GEORGE V. NASH.

**ANGULOËA** (dedicated to Don Francisco de Angulo). *Orchidaceæ*. Stout coolhouse orchids, with large pseudobulbs, the scales at the base passing into lvs.

Leaves large, plicately nerved: scapes from the base of the pseudobulbs, clothed with large lax sheaths; fls. subglobose; sepals and petals connivent, fleshy; lip shorter than sepals and petals, 3-lobed, the middle lobe much smaller than the lateral lobes, linear and recurved, or broader and 2-lipped. — Species 3, all in cult., natives of S. American Andes, at elevations of 5,000-7,000 ft.

This interesting genus comprises but few species, but these are singular, since all are well worthy of culture. Coming from the Andes of Colombia, a moderate temperature of 50° in winter will be ample for their needs, and a cool, shaded structure in summer, as the foliage is easily scorched by direct sunlight in hot weather. The peculiar structure of the flowers has given the popular name of "boat orchid," which suggests the general shape. This, together with the fragrance, and the hinged lip, which oscillates with the least movement, makes the plants very interesting when in bloom. The anguloas are rather terrestrial than epiphytal. The culture is very simple if, as a potting compost, a mixture is used containing some soil with the fiber and some sphagnum moss as a surfacing, the potting being very firm. Propagation is simple by division of the bulbs. The old back ones may be severed at the creeping rhizome after the new growth

207. *Angræcum superbum*. (× 1/6)

has been completed, and these will start new shoots usually in spring. Division must be made after the shoots are visible from the back bulbs. The black-spot disease of the bulbs is often fatal to anguloas. It appears suddenly and is generally due to too much moisture in the atmosphere or at the roots. Directly it is seen, the affected parts must be cut out clean, and dry sulfur applied; this, if done in time, will stop the progress of the disease. If brown scale attacks the plants, sponge with soap and water, taking care not to injure the tender leaves. (Orpet.)

A. Middle lobe of lip linear, recurved.

**uniflora**, Ruiz & Pav. (*A. virginalis*, Hort.). Pseudobulbs angled, ovate-oblong, 3-6 in. long; lvs. up to 2 ft. long, broadly lanceolate; fls. creamy white, often flushed or spotted internally with pink; sepals ovate, acute; petals oblong-elliptic, acute; lateral lobes of lip semi-orbicular, rounded at apex, the middle lobe linear, recurved. Peru and Colombia. G.C. III. 19:423. B.R. 30:60. B.M. 4807. Gt. 32:1137. A.F. 6:607.

AA. Middle lobe of lip ovate-triangular, 2-lipped.

B. Lateral lobes triangular, acute.

**Clowesii**, Lindl. Fig. 208. Pseudobulbs cylindric-oblong, 4-6 in. long; lvs. up to 2 ft. long, obovate-lanceolate; fls. lemon-yellow; sepals and petals acute, oblong-elliptic; lip with the lateral lobes triangular, acute, the middle lobe broadly ovate-triangular, fleshy, pubescent. Colombia. B.R. 30:63. B.M. 4313. Lind. 4:191. Veitch, Man. pl. p. 100. Var. **eburnea**, Veitch (*A. eburnea*, Williams). Differs in its ivory-white fls. Colombia.

BB. Lateral lobes semi-orbicular, rounded at apex.

**Rückeri**, Lindl. Similar to *A. Clowesii*, but smaller. Fls. green or yellowish green, flushed with brown on the outside, inside yellow densely spotted with red; sepals and petals oblong-elliptic; lip much as in *A. Clowesii*, but the lateral lobes rounded at apex. Colombia. B.R. 32:41. Gt. 3:106. A.F. 6:607. Lind. 2:53. Var. **albiflora**, Veitch. Fls. white, of waxy texture. Var. **sanguinea**, Lindl. Fls. uniformly deep red on inside. B.H. 3:31. I.H. 28:427.

*A. Cliftonii*, Hort. O. 4, pl. 3.—*A. intermedia*, Rolfe, a hybrid between *A. Rückeri* and *A. Clowesii*, was produced by Seden. This had fls. of nearly the size and shape of *A. Rückeri*.

GEORGE V. NASH.

**ANHALONIUM**. *Cactaceæ*. A name used in the first edition of this Cyclopædia, but now given place to the slightly older name *Ariocarpus*, which see. *A. Williamsii* and *A. Lewinii*, sometimes referred to *Echinocactus* or to *Mamillaria*, are here treated under *Lophophora*, which see.

**ANIGOZANTHOS** (Greek, *expanded flower*). *Amaryllidaceæ*. AUSTRALIAN SWORD LILY. About 8 Australian greenhouse or half-hardy perennials with sword-like lvs. and woolly-yellow, -green, or -red fls. in short 1-sided racemes or spikes and a much elongated perianth-tube. The two species likely to be met with are *A. flavida*, Red. (*A. coccinea*, Paxt.), with mostly red-woolly fls.  $1\frac{1}{4}$  in. long and appendaged anthers; and *A. Manglesii*, Don, with fls. about 3 in. long, red-

woolly at base and green beyond, the anthers not appendaged. These plants are little known in N. Amer.

**ANISACANTHUS** (Greek, *unequal acanthus*). *Acanthaceæ*. A genus of 6 species of Mexican and American shrubs, with mostly lanceolate, entire, petioled opposite or clustered lvs., and loosely spicate or scattered red fls. 1 in or more long; corolla-lobes 4, the tube 2-lipped, the upper lip 3-parted, the lower entire; stamens 2, equaling or exceeding the corolla-lobes.

**Wrightii**, Gray. Height, 2-4 ft.: lvs. 1-2 in. long, oblong- or ovate-lanceolate, acute or acuminate; fls. racemose, or paniculate-racemose, the corolla vermilion or purplish red,  $1\frac{1}{2}$ -2 in. long, the lip shorter than the tube; calyx deeply 5-cleft. S. and W. Texas. Offered by Franceschi of Santa Barbara, Calif.

**Gonzalézii**, Greenm. (*A. Conzatti*, Hort.). Sub-shrub, the st. much branched: lvs. 1-2 in. long,  $\frac{1}{2}$ - $\frac{3}{4}$  in. wide, acuminate, and obtuse at the apex: fls. cymose-racemose, brick-red, or scarlet and larger than in the preceding. Oaxaca, Mex.—Suitable for dry places. Intro. by Franceschi in 1911. N. TAYLOR.†

**ANISE**. *Umbelliferae*. An aromatic condimental and medicinal herb.

Anise (*Pimpinella Anisum*, Linn.) is an annual, easily grown from seeds in any warm and mellow soil. The seeds are commonly sown where the plants are to stand, and the plant matures rapidly. The seeds are used in medicine and in cookery, and for flavoring liquors; they yield a highly perfumed essential oil; they are mostly grown in Mediterranean countries. The lvs. are also used as seasoning and garnishing. The plant reaches a height of 2 ft. or less, bears twice-pinnate lvs. and small yellowish white fls. in large, loose umbels. The seeds are oblong and curved, ribbed on the convex side, grayish, the size of caraway seed. In common with all umbelliferous seed, anise seed does not retain its vitality long, the normal longevity being 1-3 years. Native from Greece to Egypt.

L. H. B.

208. *Anguloa Clowesii*.

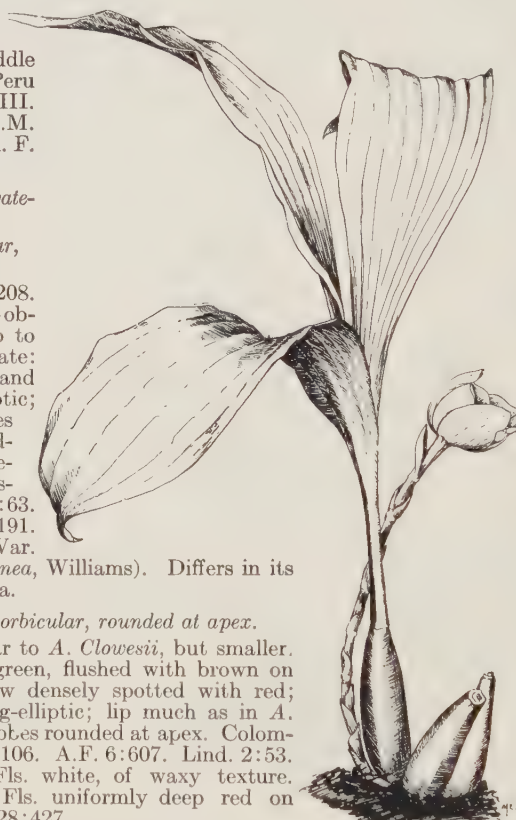

( $\times \frac{1}{4}$ )

**ANISÔTES** (Greek, *unlikeness*).

*Acanthaceæ*. Broad-leaved shrubs of about 4 Arabian and African species, one of which has been intro. to cult. recently. Fls. in short axillary clusters; sepals 5, nearly free; corolla 2-lipped, in shades of red; stamens 2, the filaments long and glabrous; fr. a caps. *A. diversifolius*, Balf., from the Isl. of Socotra, is an erect nearly glabrous shrub less than 2 ft. high: lvs. elliptic-ovate or obovate, 2 in. or less long, flame-colored or yellow, tubular and 2-lipped, the lips curved. B.M. 8219.—Warm greenhouse, blooming spring and summer. Requires the treatment given to *Justicia* and *Jacobinia*. Prop. easily by cuttings.

L. H. B.

**ANISUM**. An old generic name now referred to *Pimpinella*. *A. officinale*, D.C. (*P. Anisum*) is *Anise*, which see.

**ANNONA** (Latin, *year's harvest*, suggested by the Haitian name *anon* applied to one of the species. Commonly spelled *Anona*, but Linnæus used the double *n*). *Annonaceæ* (Richard, 1808). CUSTARD-APPLE. ARATICÚ. Tropical and subtropical woody plants cultivated for their fleshy fruits and for ornament.

Leaves 2-ranked, alternate, devoid of stipules: fls. perfect, solitary or in clusters, extra-axillary, often opposite the lvs. and sometimes subterminal; calyx usually gamosepalous, 3-parted; petals typically 6, in 2 series, but the inner series in some species reduced to small scales or even wanting; stamens numerous, crowded on the receptacle, the fleshy filament bearing a pair of linear parallel pollen-sacs on its back, these opening extrorsely by a longitudinal slit and capped by the expanded hood-like connective; pistils many, the ovaries usually clothed on the outside with minute hairs and containing a single erect ovule at the base: fr. a syncarpium, formed by the growing together of the carpels and receptacle into a fleshy mass; seeds containing a large wrinkled endosperm with small basal embryo.—Trees and shrubs, over 50 in number, chiefly from Trop. Amer., but a few from Afr., and several now widely cult. in the warmer regions of both hemispheres.

Several species have been successfully introduced into southern California and Florida. Some of those cited in catalogues and horticultural publications are merely forms of old species and others are generically distinct. Amongst these names are *A. mexicana*, which was a catalogue name used by Loddiges; *A. excelsa* of Humboldt & Bonpland, a species never fully described, the flowers and fruit of which are entirely unknown; and *A. africana*, an obscure species based by Linnæus upon an American specimen with lanceolate, pubescent leaves. *A. trilobata* and *A. obovata* are *Asimina triloba* and *Asimina obovata*; *A. asiatica* of Linnæus is not an annona at all but a rubiaceous plant, *Morinda citrifolia*; while *A. asiatica* of Loureiro is *A. reticulata*, and *A. asiatica* of Vahl is *A. squamosa*. *A. Forskahlîi* of De Candolle (*A. glabra*, Forsk., not Linn.) was based upon a specimen of *A. squamosa* growing in cultivation in Egypt; to *A. squamosa* must also be referred *A. biflora* of Mocino & Sessé, while *A. longifolia* of these authors is undoubtedly *A. reticulata*, and their *A. fruticosa* is *A. globiflora* of Schlechtendahl. *A. aurantiaca* and *A. macrocarpa* are Brazilian species, the names of which were erroneously applied to certain cultivated forms in southern California; while *A. suavissima* is only a horticultural variety of *A. Cherimola*, and *A. cinerea* of the Antilles a form of *A. squamosa*. *A. palustris* of Linnæus is identical with his previously described *A. glabra*, and the latter name must take precedence in accordance with accepted rules of priority. A number of species described as annonas belong to other genera. Among them are *A. amplexicaulis* and *A. grandiflora* of the islands of Mauritius and Madagascar, which belong to the genus *Pseudannonna*. *A. Mannii* of Oliver, an African species which has a branching inflorescence very different from that of the genus *Annona*, has been assigned to a new genus *Anonidium* by Engler & Diels; and *A. Perottetia* of A. De Candolle has been placed in the genus *Unonopsis* by R. E. Fries. *Annona obtusiflora* of Tussac, together with *A. mucosa* of Jacquin, must be placed in the genus *Rollinia* under the name *R. mucosa*, and to this genus should also be assigned the Brazilian biriba, which is probably *Rollinia orthopetala*, a species with large, fleshy fruit of delicious flavor, successfully introduced into Florida from Para. The climbing *Annona uncinata* of Lamarck belongs to the genus *Artabotrys*. *A. pyriformis*, also a climbing shrub, of Mauritius, the fruit of which is unknown, belongs undoubtedly to some other genus. For *Annona longifolia* see *Duguetia*. See also *Rollinia*, *Artabotrys* and *Cananga*.

W. E. SAFFORD.

#### Cultural notes.

While the annonas succeed best on a heavy loam, most species can be grown on light soils and under adverse conditions. The custard-apple (*A. reticulata*) thrives on the Florida keys in a semi-naturalized state; the cherimoya (*A. Cherimola*) grows and bears abundantly on steep calcareous cliffs in Central America; the sugar-apple (*A. squamosa*) is successful on dry and sandy soils with practically no attention whatever. The situation best adapted to them is a sloping piece of ground, for, with the exception of *A. glabra*, they are intolerant of stagnant water about the roots.

The cherimoya, probably the hardiest of the genus, withstands temperatures as low as 26° F. without injury, and reaches perfection only in a comparatively cool climate. The soursop (*A. muricata*) is one of the tenderest species; the sugar-apple and the custard-apple are somewhat hardier; all three are successfully grown in southern Florida, but not in California.

Propagation is usually effected by means of seeds; the most highly valued species, however, such as the cherimoya, are budded or grafted.

Seeds will retain their vitality for several years, and if planted in warm weather or under glass will germinate in a few weeks. If in a greenhouse, they may be planted at any season of the year; otherwise, it is best to plant only during spring or early summer. Sow thickly in flats or pans of light, porous soil containing an abundance of humus, covering to the depth of ½ or ¾ inch. When the plants are 3 or 4 inches high, they should be potted into 3-inch pots; care should be taken to see that the soil is perfectly drained, and waterings should not be too frequent or copious. When the plants have attained a height of 8 or 10 inches, they may either be shifted into larger pots or set out in the open ground; in the latter case, they must have careful attention until they have become established and made considerable growth.

Both budding and grafting have proved to be readily applicable to the annonas, either in the open ground or in pots, under glass. Several different species have been used for stocks, *A. Cherimola* proving the most satisfactory thus far in California, as it is best adapted to that climate; *A. glabra* has been found to be the most vigorous and satisfactory in Florida.

Shield budding, essentially the same as practised with the citrous fruits, is the method most commonly used. The work is best done in spring, shortly after the sap has begun to flow, the time varying, of course, according to locality and season. Stocks should be from ¾ to ½ inch in diameter; seedlings of this size will be eighteen months to two years old. Budwood from which the leaves have dropped, and of about a year's growth, is the most desirable. It is important that the buds be cut large,—about 1½ inches in length,—as they are likely to have difficulty in starting and be choked out, on account of the thick bark and rapid callousing of the annonas, if they are too small. The incision may be made either in the form of a T or an inverted T, raising the bark with care so that the delicate tissues lying under it will not be injured, and inserting the bud with as little pressure as possible. Waxed tape should be used for tying. Three or four weeks after insertion, the buds should be unwrapped, and, if they have united with the stock, re-wrapped loosely, lopping the stock at a point 5 or 6 inches above the bud. The wrap should not be removed until the bud has made a growth of several inches.

For grafting, two-year-old seedlings are used, the operation being a simple cleft-graft, using a scion of well-matured wood from which the leaves have dropped.

Cuttings of well-ripened wood can be rooted under glass, with bottom heat. This method of propagation is not widely practised, however.

The annonas, when grown from seed, vary greatly

in regard to productiveness as well as size, color, form, texture and quality of fruit. In southern California, many large seedling cherimoyas have been grubbed out because they were unproductive, while others produce fruit of such poor quality as to be of no value. Careful attention to culture will assist in improving the quality and size of the fruit, but the only sure way

to perpetuate choice forms and eliminate all possibility of the tree turning out to be inferior is to propagate by some asexual means.

Most species come into bearing when three or four years old. Few named varieties have been established, and these are probably confined to the cherimoya.

In some countries, the annonas are subject to certain fungous diseases and insect pests, notably the

mealy-bug. As a class, however, they seem to suffer less from these pests than most other fruit trees. They require very little pruning.

Fruits must be picked when mature,—to avoid their falling to the ground and becoming bruised,—and laid away for a few days before they are ready for eating. If they are to be shipped any distance, they must be packed in some material, such as excelsior or straw, that will allow good ventilation, each fruit being wrapped in a piece of strong paper. The selection of the toughest-skinned varieties adds greatly to the facility with which they can be shipped. F. W. POPENOE.

<i>diversifolia</i> , 5.	<i>montana</i> , 2.	<i>squamosa</i> , 9.
<i>Porskahtii</i> , 9.	<i>muricata</i> , 1, 2	<i>tripetala</i> , 6.
<i>glabra</i> , 4.		

A. Petals broadly cordate-ovate or suborbicular, the inner ones somewhat smaller than the outer.

B. Exterior petals valvate or edge-to-edge, usually acute, inner ones imbricate or overlapping, obtuse or rounded.

C. Fr. glabrous, bearing fleshy spines: lvs. glossy leathery, with minute pockets in the axils of the lateral nerves.

1. *muricata*, Linn. SOURSOP. GUANÁBANA. COROSSOL. CORAÇÃO DE RAINHA. GRAVIOLA. SUISAAS. ZUURSAAK. Fig. 209. Small evergreen tree, the size of a peach tree, in general cult. throughout the tropics of both hemispheres: lvs. leathery, ill-smelling, obovate-oblong or oblanceolate, to ovate or elliptic, acute or abruptly acuminate, glossy above and rusty beneath but at length glabrous, with the minute pockets in the axils of the lateral veins scarcely perceptible without a lens: fls. large, the exterior petals thick and fleshy, ovate-acute, valvate or edge-to-edge, the interior petals somewhat smaller and thinner, concave, rounded, imbricate or overlapping: fr. very large, fleshy, often as large as a child's head and weighing as much as 5 lbs., ovoid or heart-shaped, dark green, the glabrous ill-smelling skin bearing numerous recurved fleshy spines; pulp white and juicy, pleasantly subacid, with a slight mango-like flavor. Of Trop. Amer. origin,

but now common in the tropics of the Old World.—As in all cult. frs., there is more or less variation in its flavor. It is easily prop. from the seed or from buds, and is undoubtedly capable of improvement by selection. It begins to bear at a very early age and is consequently one of the most valuable fr. trees of the tropics. It is grown with especial excellence in Porto Rico, and is common in the markets of Key West, whither it is shipped from the islands to the southward. A favorite drink is made from the juice, and the pulp yields excellent jelly, tarts and preserves. Care must be taken, however, to remove the skin in preparing the fr. for the table.

2. *montana*, Macfadyan (*A. muricata*, Velloso, not Linn.). MOUNTAIN SOURSOP. GUANÁBANA CIMARRONA. COROSSOLIER BÂTARD. ARATICÚ PONHÊ. A forest tree, sometimes reaching the height of 45 ft., but usually of smaller dimensions: lvs. resembling those of the soursop, varnished above and dull beneath, with the pits in the axils of the lateral nerves often conspicuous: fls. similar to those of the soursop, solitary or in pairs. fr. spheroid or broadly ovoid, varying from the size of an orange to 6 in. diam., green at first, at length turning yellowish; skin glabrous, bearing numerous short erect fleshy spines; pulp not edible. This species, which is larger and more robust than the closely allied *A. muricata*, has been intro. into Fla. for use as stock upon which to bud other species of the genus. W. India. and N. S. Amer.; thus far unknown from Mex. and Cent. Amer.—The peculiar pits, or pockets in the axils of the lateral nerves of the lvs. set apart this species, together with *A. muricata*, from all other species of the genus.

cc. Fr. covered with felt-like tomentum, bearing rigid stout pyramidal spines often hooked at the tip: lvs. very large, subcoriaceous or membranaceous, undulate without axillary pockets.

3. *purpurea*, Mocino & Sessé. NEGRO-HEAD. CABEZA DE NEGRO. SONCOYA. SENCUYA. TORETA. Fig. 210. A small or medium-sized tree, sometimes reaching the height of 25 ft., the younger branches clothed with reddish tomentum but becoming glabrate at length: lvs. large, membranaceous or subcoriaceous, undulate, oblong-elliptical to oblong-obovate, acuminate at the apex, rounded or obtusely cuneate at the base, 8–12 in. long and 4–5½ in. broad; petioles short and thick: fls. resembling those of *A. muricata* but sessile or nearly so, solitary, extra-axillary, sometimes opposite a lf., inclosed when very young in an involucre of 2 bracts, the apex of which becomes more or less shriveled at length, and the base persists somewhat like an outer or second calyx; calyx 3-lobed, ferruginous-velvety on the outside; 3 outer petals very thick, valvate, usually acute or acuminate, sometimes obtuse at the apex, ferruginous-velvety on the outside, stained with purple within; inner petals overlapping, thinner and rounded, forming a dome-like covering over the essential parts, whitish on the outside, purple within; terminal connectives of the stamens velvety carpels distinct at first, the hirtellous ovaries crown. by 2

210. *Annona purpurea*. ( $\times \frac{1}{4}$ )

prismatic style about  $\frac{1}{8}$  in. long; fr. large, spheroid or broadly ovoid, sometimes 6–8 in. diam., covered with a brownish felt-like indumentum and bearing numerous pyramidal protuberances, grooved longitudinally on the ventral side and usually terminating in a hook directed toward the peduncle; seeds large, obovate, more or less flattened and marginate, sometimes exceeding an inch in length by  $\frac{1}{2}$ – $\frac{3}{4}$  in. broad; pulp fleshy, fibrous, very fragrant, edible, with a flavor somewhat like that of a mango. Mex. to Panama and perhaps N. S. Amer. It is abundant on the Isthmus of Tehuantepec and is sold in the markets of Veracruz.—The frs. differ considerably in flavor. Some of those on the Isthmus of Panama are reputed to be excellent, though here, as elsewhere, they are supposed to induce chills and fever. Intro. into S. Calif., but imperfectly known in cult. Like its congeners, it is undoubtedly capable of improvement by careful selection.

BB. *Exterior and interior petals both valvate or edge-to-edge and usually acute.*

4. *glabra*, Linn. (*A. palustris*, Linn. *A. laurifolia*, Dunal). POND-APPLE. ALLIGATOR-APPLE. MONKEY-APPLE. MANGROVE-ANNONA. MAMIN. MAMAIN. CACHIMAN-COCHON. CAYUL. CAYURES. CORK-WOOD. PALO BOBO. BOIS-FLOT. CORCHO. CORTISSO. ARATICÚ DO BREJO. Fig. 211. Small to medium-sized tree, sometimes reaching a height of 45 ft., growing in swampy places and along the banks of streams; young growth smooth: lvs. smooth and laurel-like, glossy green above, paler beneath, evergreen, ovate to oblong or elliptic, usually acute or acuminate but sometimes bluntish at the apex and rounded or tapering at the base: fls. fragrant, varying considerably in size, those of trees growing in favorable situations larger than those growing in crowded mangrove swamps; outer petals cream-colored or pale greenish yellow when fresh, usually marked within by a deep red spot near the base; inner ones somewhat shorter and narrower, whitish or dull greenish outside, usually blood-red within or spotted with red or wine-color near the base: fr. the size of a bellflower apple with a smooth leathery skin, green at first, at length yellowish, its surface covered with indistinctly outlined areoles, but these never elevated or squamose; pulp cream-colored when ripe, not edible except by iguanas and other animals. Everglades of Fla. and banks of the Indian and Caloosahatchee Rivers; also the tropical shores of Amer., W. Indies, west coast of Afr., and the Galapagos Is. — Statements that the fr. is sold in the markets of Mex. and that the tree is cult. for its fr. are based upon the confusion of other species of annona having smooth frs. with this. This species is essentially tropical and swamp-loving. Its light spongy roots are used as a substitute for cork and for floats of fishing-nets; hence its name cork-wood.

211. *Annona glabra*.  
( $\times \frac{1}{2}$ )

AA. *Petals (exterior) linear or oblong, the inner ones minute and scale-like.*

B. *Peduncles with broad persistent lf.-like bracts at the base.*

5. *diversifolia*, Safford. ILAMA. ILAMATZAPOTL. Fig. 212. Small tree with brownish-gray, aromatic, longitudinally furrowed bark; young growth glabrous,

212. *Annona diversifolia*. ( $\times \frac{1}{4}$ )

with prominent lf.-scars bordered with a margin of pale rufous hairs: lvs. thin, membranaceous, glabrous, variable in form, those near the base of the branchlets broadly elliptical and rounded at the base, those higher up oblanceolate, rounded at the apex and acute or cuneate at the base, the largest 4–5½ inches long and 1½–2 inches broad with petioles exceeding  $\frac{1}{2}$  inch in length: peduncles long and slender, recurved, glabrous, issuing from 2 suborbicular, lf.-like, amplexicaul bracts at the base of the branchlets; fl.-buds obpyriform, calyx-divisions broadly ovate or triangular, terminating at the points in a tuft of ferrugineous hairs; outer petals linear-oblong, swollen at the base and concave within, sparsely rusty-pubescent on the outside; inner petals minute, pubescent on the back and bearing 2 rudimentary pollen-sacs; carpels distinct, glabrous near the base, rufous hirtellous above, at length growing together into a compound fr. or syncarpium: fr. large, conoid or broadly ovoid with an axis of about 6 in. and a diam. of 5 in., clothed with dense grayish felt-like tomentum and when mature usually bearing stout thick protuberances directed toward the apex, but these sometimes suppressed; pulp edible, cream-colored or rose-tinted; seeds hard, smooth and nutlike, golden brown or tan-colored. Mts. and foot-hills west coast of Mex. to Salvador.—The fr. is offered for sale in the markets of Colima and Acapulco. It is described by American Consul Marion Letcher, stationed at Acapulco, as shaped like a pineapple cheese, with delicious pink-tinted pulp; and Samuel E. Magill, American Consul at Guadaluajara, states that the frs. grown on the side of the volcanos of Colima and Cerro Grande are of unusually fine quality. This species has been intro. into S. Fla.

BB. *Peduncles devoid of lf.-like bracts at the base.*

c. *Lvs. velvety beneath.*

6. *Cherimòla*, Mill. (*A. tripétala*, Ait.). CHERIMOYA. CHERIMOYA. CHERIMOYER. CHERIMOLLA. Tree, 15–25 ft. high, with young growth fulvous tomentose: lvs. persistently velvety-tomentose beneath, sparsely pubescent above, ovate to ovate-lanceolate or obovate, sometimes elliptical, obtuse at the apex or obtusely acuminate, usually rounded at the base: fls. fragrant, extra-axillary, often opposite a lf. at the base of a branchlet, usually solitary but sometimes 2 or 3 on short nodding tomentose peduncles, the exterior petals oblong-linear, not exceeding 1¼ in. length, keeled on the inside and excavated at the base, greenish yellow or rufous on the outside and clothed with velvety tomentum, pale yellow or whitish within and marked with a purple spot at the base; inner petals very small, squa-

mose, ovate or triangular, usually flesh-colored or purple and keeled on the outside; fr. variable in shape and appearance, sometimes conoid or heart-shaped, with surface bearing protuberances; sometimes spheroid or ovoid with the surface covered with concave or squamose U-shaped areoles, each bearing a small wart or tubercle; and sometimes quite smooth or with the surface having the appearance of putty marked by finger-prints; pulp white, edible, pleasantly acidulous, easily separable from the seeds; seeds usually obovate, obliquely truncate, somewhat compressed, with a thin

213. *Annona reticulata*. ( $\times \frac{1}{4}$ )

membranous brown testa which is usually more or less wrinkled or pitted, owing to the wrinkled surface of the inclosed endosperm. Andes of Peru and adjacent regions, but naturalized at a very early date in Mex. and Cent. Amer. Successfully intro. into S. Calif., Canary Isls., Madeira, the mts. of India, and Hawaii. Essentially a subtropical plant which does not yield good results in low tropical countries.—Frs. of exquisite flavor are produced on the island of Madeira, where the trees are trained on trellises and are taking the place of grapes in the economy of the island. Excellent results have also been secured in S. Calif. See *Cherimoya*.

7. *longiflora*, Wats. WILD CHERIMOYA OF JALISCO. A shrub or small tree, 3–10 ft. high; young growth softly pubescent; branches with prominent lf.-scars, which are clothed with a marginal collar of plush-like hairs; lvs. resembling those of *A. Cherimola* but distinguished when mature by being glabrate or glabrescent between the lateral nerves, which together with the midrib are persistently velvety pubescent, the blades 2–5½ in. long and 1½–3¼ in. broad, elliptical to obovate-elliptical, usually rounded but sometimes acute at the base and rounded at the apex, which is often minutely apiculate; fls. short-peduncled, pubescent, the calyx-divisions deltoid-ovate, clothed on the outside with fine soft hairs, the outer petals leathery, often 2 in. long, linear-oblong or oblong-lanceolate in shape, cream-colored or whitish, and marked within with a dark purple or blackish spot at the excavated base; inner petals minute (sometimes wanting), ovate, obtuse, finely pubescent; carpels distinct, the ovaries clothed with rufous hairs, and the styles minutely puberulent; fr. conoid or globose-ovate, its surface covered with protuberances or with reticulated areoles; pulp white, resembling that of *A. Cherimola* in flavor. State of Jalisco, Mex., especially in vicinity of Guadaluajara and Tequila. Intro. into S. Calif., but as yet little known.

cc. Lvs. not velvety.

d. Fr. smooth or nearly so, its surface divided into angular areoles by impressed lines; pulp tallow-like.

8. *reticulata*, Linn. (*A. longifolia*, Mocino & Sessé). COMMON CUSTARD-APPLE. BULLOCK'S-HEART. CORAZON. COROSSOL CŒUR-DE-BŒUF. CORAÇÃO DE BOI. MAMON. ANONAS. ANONA COLORADA. QUAUHTZAPOTL. Fig. 213. A deciduous tree, 15–25 ft. high with young growth fulvous-pubescent, at length glabrate; lvs. approximate, oblong-lanceolate or lanceolate, acute at the apex, conduplicate, glabrate, or with the midrib and lateral nerves sparsely pubescent; fls. in extra-

axillary clusters of several issuing from the new branchlets, peduncles nodding; outer petals fleshy, oblong-linear, keeled on the inside and excavated at the base, olive-green or yellowish, usually stained within with purple and with a dark purple blotch at the base; inner petals very small, scale-like, ovate, acute; carpels distinct, the ovaries covered with pale brown silky hairs, at length uniting to form a solid fr.: fr. 3–5 in. diam., smooth, with the surface divided into rhomboid or hexagonal areoles by impressed lines, usually reddish or reddish brown when ripe, or red-cheeked on the sunny side, pulp sweetish but insipid, tallow-like and usually granular, adhering closely to the seeds. Trop. Amer.; now widely spread throughout the tropics of both hemispheres.—A robust tree which has spread spontaneously in the forests of the Philippines, the island of Guam and the E. Indies, while its congeners, *A. muricata* and *A. squamosa*, occur usually only where planted. It is essentially tropical while the cherimoya, with the smooth-fruited forms of which it has often been confused, is subtropical. Its fr. is inferior in flavor to both the cherimoya and the sugar-apple (*A. squamosa*), from the first of which it may be distinguished by its long, narrow, glabrate lvs., and from the second by its solid, compact fr., as well as its larger lvs. From *A. glabra*, with which it is also confused, it may be distinguished by its elongate narrow outer petals and its small, dark brown seeds. It is common in the W. Indies and thrives in S. Fla.

dd. Fr. composed of rounded carpels loosely cohering when ripe, covered with a glaucous bloom; pulp creamy or custard-like.

9. *squamosa*, Linn. (*A. cinerea*, Dunal. *A. Forskählii*, DC. *A. biflora*, Mocino & Sessé). SUGAR-APPLE. SWEET-SOP. ANON. ATTA. ATIS. POMME-CANNELLE. KESCHTA. FRUTA DA CONDESSA. AHATE DE PANUCO. STEENAPPEL. TEXALTZAPOTL. PINHA. Fig. 214. A small deciduous tree, 15–20 ft. high, with irregularly spreading branches and zigzag branchlets bearing approximate 2-ranked lvs.; young growth pubescent, at length glabrate or clothed with scattered hairs and dotted with lenticels; lvs. conduplicate, resembling those of *A. reticulata*, but smaller, usually lanceolate or oblong-lanceolate, acute or shortly acuminate at the apex and acute or cuneate at the base, sometimes ovate or elliptical and rounded at the base with a tendency to be asymmetrical, membranaceous, minutely punctate with both surfaces pale green; sparsely hairy at first, at length glabrate or nearly so, except the petiole, which is pubescent; fls. borne on the young branchlets, closely resembling those of *A. reticulata*, extra-axillary, usually in clusters of 2, 3, or 4, but sometimes solitary; peduncles slender, sparsely and delicately pilose, at length glabrate, bearing a minute bracteole below the middle, which terminates in a tuft of floccose hairs; outer petals oblong-linear, thick, triquetrous, rounded at the apex and

214. *Annona squamosa*. ( $\times \frac{1}{4}$ )

excavated at the base, greenish yellow, usually marked within by a wine-colored or purplish red spot at the base; inner petals minute, ovate or obovate, keeled on the outside; stamens with broad terminal connectives of a cinnamon-brown or orange-red color; carpels distinct, clothed with pale brown hairs, sulcate on the ventral side and terminating in oblong or taper-pointed styles: fr. about the size of an orange, spheroid or heart-shaped, composed of loosely cohering carpels rounded at the extremities and grooved on the inner side, forming a squamose or tuberculated surface, greenish yellow and covered with a glaucous bloom at first, but soon turning black in spots when handled, and the waxy bloom easily rubbed off; pulp yellowish white, creamy or custard-like, very sweet and pleasantly flavored; seeds dark brown, smooth, closely resembling those of *A. reticulata*. Trop. Amer., now widely cult. in all tropical countries.—Less robust than *A. reticulata*, with fr. much more highly prized, and produced several times during the year instead of only once, as in that species. Like *A. reticulata*, it is essentially tropical and will not thrive in subtropical regions which are suitable for the cult. of the cherimoya. It has been intro. into S. Fla. Delicious sherbets are made from its custard-like pulp, often with the addition of a little lemon juice, but it is never cooked or made into preserves or jelly, like the soursop. The fr., when green, as well as the seeds and lvs., is used for destroying vermin; and the crushed lvs., in the form of poultices, are applied to ulcers and malignant sores in the W. Indies. The root is a drastic purgative.

W. E. SAFFORD.

**ANNUALS.** What are known to gardeners as "annuals" are plants that bloom in the open the same year the seeds are sown and that do not live over winter.

These plants are not necessarily true annuals; for annuals in the botanical sense are plants that normally complete their entire life-cycle within one vegetation-year. Perennial plants that bloom freely from seed the first year and do not usefully survive till another year may be classed as annuals by the gardener and treated as such: these are properly plur-annuals, a group standing midway between annuals and perennials. The garden *Nicotiana affinis* (properly *N. alata*) and pinks and snapdragons are such. It may be said that plur-annuals are plants of somewhat indefinite duration that are terminated by cold weather rather than by their normal maturity within the season. Many real perennials, as castor bean, are treated as annuals in northern gardens.

Some of the biennial plants—those that normally bloom and perish in the second year—may flower the first year if the seeds are sown early and the plants are hurried along. Of these, Canterbury bell, ipomopsis and some of the *cenotheras* are examples. See *Biennials*.

The annuals of gardens are grown directly from seeds, in usual practice. Some plants are reared annually from bulbs or tubers, as crocus, lilies, potato: these are really perennials that die each year to the ground and do not perish root and branch. To these plants the name pseud-annuals (i.e., false annuals) has been given.

Among the true annuals there are many grades. Some of them are winter annuals, growing in the cool part of the year and carrying over winter under the snow, as the common creeping chickweed and other crucifers. In the arid regions of the West, many annual plants spring into growth with the rains and thrive in the cool months. Many of the annuals are summer annuals and others are autumn annuals: these two classes are practically the only ones that are cultivated in the open for ornament.

Among the annuals are found some of the most

showy garden flowers. As a rule, they are easily grown, producing quick results and affording a great variety of colors, forms and foliage. Some of the annuals last only a few weeks in bloom, others continue throughout the summer. There are trailers and climbers, dwarfs and tall growers. By a judicious selection and arrangement of kinds, the handsomest effect may be produced. Many of the showy kinds are adapted to mass effects, while the dwarf-growing sorts make good flowering edgings for beds or walks. With the latter, handsome ribbon-beds are possible, but this requires care in the selection of kinds, and as the use of the trimming shears is almost precluded, it is best to limit oneself to simple designs. Annuals are well suited to the covering of bare spots of ground in the border. Like other flowers, they display best when seen against a background of foliage. The tall and leafy kinds make excellent covers for unsightly objects. For climbing and twining kinds, see *Vines*. See, also, *Everlastings* and *Grasses*.

*Classification as to hardiness.*

It is customary to divide annuals into three classes: (1) Hardy annuals are those that are sown directly in the open ground where they are to grow. They are

215. Annuals filling the formal space between a drive and a tree-group.

vitality strong, developing without artificial heat, and may be sown from February to May, according to the season and latitude. Some of them, as sweet peas, may be sown even in the fall. For this class, a well-prepared border on the south side of a fence or wall, or other sheltered place, is usually preferred for early sowings. From here the seedlings are transplanted later where they are to grow. Some sorts, however, do not bear transplanting well, consequently must be sown in the places they are to occupy. Among such are poppies, *eschscholtzia*, *bartonia*, Venus' looking-glass, lupine, malope, and the dwarf *convolvulus*. (2) Half-hardy annuals are usually sown in February or March in the window or a warm frame. The season is usually not long enough to enable them to reach full development in the open. In the early stages of growth they need protection and warmth. Such kinds are sometimes sown in the fall and wintered over in a coldframe. When once established, they are hardy with slight protection. Some of the kinds are grown to their greatest perfection only in this way. (3) Tender annuals require still more warmth, and are started from January to May in the greenhouse or other suitable place. They commonly need a temperature of 60° to 70°. The danger with early-grown seedlings, especially those started in the window, is over-crowding and want of light. As soon as crowding begins, the plants should be

thinned out or transplanted to other trays, or into pots, and reset from time to time, as they need; frequent transplanting is usually an advantage. The last transplanting is preferably into small pots, as then the seedlings may be readily set in the open ground at the proper time, with little or no check.

#### *Seed-sowing.*

The greater number of common annuals will bloom freely if the seeds are sown in the open ground when the weather becomes thoroughly settled. But there are some kinds, as the late cosmos and moonflowers, for which the northern season is commonly too short to give good bloom unless they are started very early indoors.

In the case of others than the continuous bloomers, a succession of sowings or plantings is desirable to provide for a continuous display; then as a kind begins to fail, its place may be filled with young plants of the same

Vigorous June-sown plants are better than such weaklings. It must be remembered, however, that very early bloom usually means the shortening of the season at the other end; this may be remedied to some extent by making sowings at different times.

Only the best seeds should be purchased, and it is usually best to get the colors in separate packets. In the open ground, seeds may be covered to a depth of four or five times their own thickness, but when sown indoors in trays or pots, the rule is to cover them to about their own thickness. After covering, the soil should be pressed firmly over the seed with a board or hoe, or the feet. In soils that are inclined to bake, a sprinkling of sand or fine litter over the surface after sowing will remedy this evil. Evergreen boughs placed over the beds until the seedlings have appeared will afford useful shelter from beating rains. It is desirable to sow the seeds thickly. For the reception of seeds, the surface should

be mellow and smooth. The seeds are sown in drills or concentric circles, according to the method of planting decided upon. Taller-growing kinds are sown toward the center or back of the bed. When up, the plants may be thinned to their proper distances. Particular care should be given to this matter, and to keeping down weeds, or the plants may become weak, spindling and valueless. Much trouble will be avoided if each seed-row is plainly labeled or marked so

216. A semi-formal garden space of annual flowers.

or other species. The usual method of securing succession is to sow the seeds in flats, or beds, and transplant the seedlings first to pots. The potted plants may be set out at any time, with but little check to growth.

When flowers of any annual are wanted extra early, the seeds should be started indoors. It is not necessary to have a greenhouse for this purpose, although best results are to be expected with such a building. The seed may be sown in boxes, and these boxes then placed in a sheltered position on the warm side of a building. At night they may be covered with boards or matting. In very cold "spells" the boxes should be brought inside. In this simple way seeds may often be started one to three weeks ahead of the time when they can be sown in the open garden. Moreover, the plants are likely to receive better care in these boxes, and therefore to grow more rapidly. Of course, if still earlier results are desired, the seed should be sown in the kitchen, hotbed, coldframe, or in a greenhouse. In starting plants ahead of the season, be careful not to use too deep boxes. The gardener's "flat" may be taken as a suggestion. Three inches of earth is sufficient, and in some cases (as when the plants are started late) half this depth is enough.

One trouble with early sown seedlings is "drawing up," and weakness from crowding and want of light. This is most likely to occur with window-grown plants.

that the young plants may be distinguished from the weeds, with which they must often compete.

#### *Soils and places.*

Most annuals thrive best in an open, sunny situation, but pansies, forget-me-nots, and some others, thrive where they get the full sunshine for only half the day. Some of the kinds are at their best in full sunlight, as portulaca, sunflower, and zinnia. In all cases the best results are secured only when the soil is well enriched and thoroughly prepared previous to sowing or planting; and it is far better to make this preparation a fortnight or more in advance. A considerable proportion of humus in the soil is desirable, rendering it less subject to baking and drying out. Cow-manure, stable-manure or leaf-mold, worked in liberally, will supply this. Beds should be spaded thoroughly and at least a foot deep. If the surface is then again worked over to half this depth, better results will be obtainable. The soil should not be disturbed, however, unless it pulverizes readily.

When the flowers are to be grown about the edges of the lawn, make sure that the grass roots do not run underneath them and rob them of food and moisture. It is well to run a sharp spade deep into the ground about the edges of the bed every two or three weeks for the purpose of cutting off any grass roots that may have

run into the bed. If beds are made in the turf, see that they are 3 feet or more wide, so that the grass roots will not undermine them. Against the shrub borders, this precaution may not be necessary: it is desirable that the flowers fill all the space between the overhanging branches and the sod.

The plants should not be allowed to bear seed, else they will be exhausted and the season of bloom will be short. Sweet peas, for example, soon spend themselves and dry up if the pods are allowed to ripen. The frequent cutting of blooms prolongs the season.

#### The kinds.

Most of the staple or general-purpose types of annuals in the North are the following: petunias, phloxes, pinks or dianthus, larkspurs or delphiniums, calliopsis or coreopsis, pot marigolds or calendulas, bachelor's buttons or *Centaurea Cyanus*, clarkias, zinnias, marigolds or tagetes, collinsias, gillias, California poppies or *eschscholtzias*, verbenas, poppies, China asters, sweet peas, nemophilas, portulacas, silenes, candytufts or iberis, alyssum, stocks or matthiolas, morning-glories, nasturtiums or tropaeolums, wallflowers, gaillardias, snapdragons, coxcombs, lobelias, four-o'clocks, amaranths, balsams, sweet sultans, salpiglossis, scabiosas, nicotianas, and pansies. Other species are mostly of special or particular use, not general-use types. In the South, and occasionally at the North, some of the annuals come up voluntarily year after year from self-sown seeds, e. g., petunias, phloxes and morning-glories.

Late sowings, even as late as June in the latitude of New York City, may be made of such things as China aster, sweet alyssum, California poppy (*Eschscholtzia*), calliopsis or coreopsis, portulaca, calendula, phlox, zinnia, marigold, candytuft, mignonette, petunia. Late-blooming beds of these and other annuals may be secured by this delayed sowing. The tendency to sow everything for early bloom deprives the garden of much freshness and interest in autumn.

The numbers of varieties in some of these long-cultivated species-groups are surprising large, and they often appeal to collectors. If a collector desires annuals for autumn display, for example, he will find that zinnias have about forty current varieties, annual pinks about fifty, petunias about sixty, pansies sixty to seventy, balsams over sixty, and stocks perhaps 300, all of which may be prolonged more or less into autumn. But the most appropriate and varied of these annuals are the China asters, which have about 450 varieties. Owing to the greater variety of everything abroad, collectors naturally send to Europe for large collections, and the very low duty on flower seeds has stimulated the collecting of annuals. Perennial flowers are more difficult to import, but many persons have recently imported fifty or more varieties of the following: gaillardia about 100 varieties, hardy chrysanthemums 100 and more, florists' pentstemons more than 150 (not sufficiently hardy), delphiniums over 200, and phlox 350. Unfortunately, collections of a single flower rarely give an artistic effect, even when at their best, owing to the difficulty of isolating troublesome colors in a garden that must be sunny, failures among highly bred varieties, the fact that the early, midseason and late sections mix poorly, and so on. The obvious limitation of gardens devoted to one kind of flower is that they are unattractive out of season, and therefore it is best to isolate them. There are practically no annuals that bloom satisfactorily throughout summer and autumn.

Background plants, for bold mass-displays of color in the rear parts of the grounds or along the borders may be secured from some of the coarser species. Good plants for such use are: sunflower and castor-bean for the back rows; zinnias for bright effects in the scarlets and lilacs; African marigolds for brilliant yellows; nicotianas for whites. Unfortunately, we have no ro-

bust-growing annuals with good blues. Some of the larkspurs and the browallias are perhaps the nearest approach to them.

For lower-growing and less prominent mass-displays, the following are good: California poppies for oranges and yellows; sweet sultans for purples, whites, and pale yellows; petunias for purples, violets, and whites; larkspurs for blues and violets; bachelor's buttons (or corn-flowers) for blues; calliopsis and coreopsis and calendulas for yellows; gaillardias for red-yellows and oranges; China asters for many colors except yellows.

For still less robustness, good mass-displays can be made with the following: alyssums and candytufts for whites; phloxes for whites and various pinks and reds; lobelias and browallias for blues; pinks for whites and various shades of pink; stocks for whites and reds; wall-flowers for brown-yellows; verbenas for many colors.

Vines are abundant among the annuals, the most prominent being morning-glory, sweet pea, cobeas, climbing nasturtium, Japanese hop, cypress-vine and other ipomœas, balloon-vine, scarlet-runner, moon-flowers in the South.

Some of the "everlastings" or immortelles are useful as flower-garden subjects as well as for "dry-bouquets." These "paper flowers" are always interesting to children. The colors are bright, the blooms hold long on the plant, and most of the kinds are very easy to grow. Favorite groups are the different kinds of xeranthemums and helichrysums. The globe amaranths, with clover-like heads (sometimes known as bachelor's buttons), are good old favorites. Rhodanthes and acrocliniums are also good and reliable.

Ornamental grasses should not be overlooked. They add a note to the flower-garden and to bouquets that is distinct and can be secured by no other plants. They are easily grown. Some of the good annual grasses are *Agrostis nebulosa*, the brizas, *Bromus brizaeformis*, the species of *eragrostis*, and pennisetums and *Coix Lachryma* as a curiosity. Such good lawn grasses as arundo, pampas-grass, eulalias, and erianthus are perennials and therefore are not discussed here.

The amateur would do well to make up lists from the most detailed seed catalogues. The following short lists (under trade names) suggest a few things in several categories:

#### White-flowered annuals.

<i>Ageratum mexicanum</i> album.	Matthiola (Stocks), Cut-and-Come-Again; Dresden Perpetual; Giant Perfection; White Pearl.
Alyssum, common sweet.	Mirabilis longiflora alba.
<i>Centranthus macrosiphon</i> albus.	Nigella.
China asters.	Phlox, Dwarf Snowball; Leopoldi.
<i>Convolvulus</i> major.	Poppies, Flag of Truce; Shirley; The Mikado.
Dianthus, Double White Margaret.	Zinnia.
<i>Iberis amara</i> ; coronaria.	
<i>Ipomœa hederacea</i> .	
<i>Lavatera</i> alba.	
<i>Malope grandiflora</i> alba.	

#### Yellow- and orange-flowered annuals.

<i>Cacalia lutea</i> .	Hibiscus africanus; Golden Bowl.
<i>Calendula officinalis</i> , common; Meteor; sulphurea; suffruticosa.	<i>Ipomœa coccinea</i> lutea.
<i>Calliopsis bicolor</i> marmorata; cardaminifolia; elegans.	Loasa tricolor.
<i>Cosmidium Burridgeanum</i> .	Tagetes, various kinds.
<i>Dimorphotheca aurantiaca</i> .	Thunbergia alata Fryeri; aurantiaca.
<i>Erysimum Perofskianum</i> .	Tropaeolum, Dwarf; Lady Bird; Tall, Schulzii.
<i>Eschscholtzia californica</i> .	Zinnia.

#### Blue- and purple-flowered annuals.

<i>Ageratum mexicanum</i> ; mexicanum Dwarf.	<i>Iberis umbellata</i> ; umbellata lilacina.
Browallia Czerniakowski; elata.	Kauffussia amelloides; atrovioacea.
<i>Centaurea Cyanus</i> , Victoria Dwarf Compact; Cyanus minor.	Lobelia Erinus.
China asters of several varieties.	Nigella.
<i>Convolvulus</i> minor; minor unicaulis.	Phlox variabilis atropurpurea.
<i>Gilia achilleæfolia</i> , capitata.	Salvia farinacea.
	Specularia.
	Verbena, Black-Blue; cœrulea; Golden-leaved.
	Whitlavia gloxinoides.

*Rose- and rose-red-flowered annuals.*

Cacalia, Scarlet.	Papaver (Poppy) cardinale;
Clarkia elegans rosea.	Mephisto.
Convolvulus tricolor roseus.	Phaseolus multiflorus.
Dianthus, Half-Dwarf Early	Phlox, Large-flowering Dwarf;
Margaret; Dwarf Perpet-	Dwarf Fire-ball: Black
uai chinensis.	Warrior.
Gaillardia picta.	Salvia coccinea.
Ipomœa coccinea; volubilis.	Saponaria. [Thumb.
Matthiola annuus; Blood-Red	Tropœolum, Dwarf, Tom
Ten Weeks; grandiflora,	Verbena hybrida, Scarlet Defi-
Dwarf.	Zinnia. [ance.

*Annuals useful for edgings of beds and walks, and for ribbon-beds.*

Ageratum, blue and white	Leptosiphons.
Alyssum, sweet.	Lobelia Erinus.
Brachycome.	Nemophilas.
Calandrinia.	Nigellas.
Clarkia.	Portulacas or rose moss.
Collinsias.	Saponaria calabrica.
Dianthus or pinks.	Specularia.
Gilia.	Torenia.
Gypsophila muralis.	Whitlavia.
Iberis or candytufts.	

*Late-blooming annuals.*

Probably the best annuals to bloom in late fall, even after the first frosts, are petunia, phlox, and verbena. Other excellent kinds are ageratum, alyssum, antirrhinum or snapdragon, *Calendula officinalis*, California poppy, gaillardia, marigold, and pansy. The list may be extended by

Abronia umbellata.	Erysimum Perofskianum; ar-
Adonis œstivalis; autumnale.	kansanum.
Argemone grandiflora.	Gilia achilleæfolia; capitata;
Callirhoe.	laciniata; tricolor.
Carduus benedictus.	Iberis affinis.
Centaurea Cyanus (bachelor's	Lavatera alba.
button).	Matthiolas or stocks.
Centaureidum.	(E)nothera rosea; Lamarekiana;
Centranthus macrosiphon.	Drummondii.
Cerinthe retorta.	Podolepis affinis; chrysantha.
Cheiranthus Cheiri.	Salvia coccinea; farinacea; Hor-
Chrysanthemums.	vicia Gerardii. [minum.
Convolvulus minor; tricolor.	Virginian stocks.
Dianthus of various kinds.	Viscaria elegans; oculata; Cœli-
Elsholtzia cristata.	rosa.

If sown early or in the fall, bachelor's button, annual gypsophila and poppy will re-seed and furnish plants for late fall bloom.

L. H. B.†

**ANÆCTOCHILUS** (Greek, *open lip*). *Orchidaceæ*. A group cultivated for the beautifully reticulated leaves, which are oval or ovate, membranaceous and diversely colored; the flowers are small, not ornamental.

Terrestrial, from a creeping rhizome: lvs. basal: fls. in a spike or raceme; sepals free, the dorsal erect, forming a hood with the petals, the lateral sepals spreading; lip adnate to the foot of the column, spreading; claw fimbriate, the blade 2-lobed.—About 8 species.

Although many methods have been adopted for the successful cultivation of the best species and varieties, failure has been the rule, so that at present few American collections contain even a single specimen. Plants introduced by collectors sometimes thrive for a few years and then fail, in spite of all efforts. Frequently they can be kept only a year or two.

**Bullenii**, Low. Lvs. about 2 in. long, bronze-green, with 3 longitudinal bands of copper-red. Borneo.

**regalis**, Blume. Fig. 217. One of the most attractive species of the group: lvs. oval, large, bronze-green netted, veined with gold, the surface of the lvs. like velvet. Java. B.M. 4123. F.S. 2:79 (both as *A. setaceus*).—Several good varieties exist.

**Röxburghii**, Lindl. Lvs. ovate, median line of pale green, reticulated and veined with gold. Java and India.

Several kinds are described and figured in foreign publications, but they are all fanciers' plants. Other names which appear in the American trade are: *A. Dayana* = (?) — *A. Dawsonianus* = *Hemaria*. — *A. Frédéric-Augustii*, Reichb. f. (*A. xanthophyllus*, Planch.). Lvs. dark velvety green, the broad orange stripe down the center covered with a network of gold.

G. 10:675; 27:54. — *A. Löwis*, Hort. = *Dossinia*. — *A. Petöla*, Hort. = *Macodes*. — *A. Veitchianus*, Hort. = *Macodes*.

GEORGE V. NASH.†

**ANOGRÁMMA** (Greek, *without lines* referring probably to the absence of indusia). *Polypodiaceæ*. A small group of tropical ferns, somewhat related to *Pteris*, and characterized by linear sori uncovered by indusia. The lvs. are borne in a cluster, are small, 1-2 pinnate with pinnatifid divisions and forking veinlets.

**schizophýlla**, Diels. (*Gymnogramma schizophýlla*, Baker). Lvs. 18-24 in. long, quadri-pinnatifid, the stalks, rachises and divisions slender, the ultimate segms. finely cut. A comparatively recent intro.; very graceful in cult. Jamaica. A.G. 18:421. G.F. 2:533. A.F. 10:827. I.H. 31:522. Gn. 48, p. 417. Var. *elegantissima* (*Gymnogramma elegantissima*, Hort. W. Bull.), has reddish brown rachises.

R. C. BENEDICT.

**ANOIGÁNTHUS** (from Greek words, alluding to the expanded flower). *Amaryllidaceæ*. A small probably monotypic genus of Natal and the Cape region, the plants sometimes cult. as greenhouse winter- and spring-flowering bulbs. *A. breviflorus*, Baker (*Cyrtanthus breviflorus*, Harv.), has an ovoid bulb 1 in. diam., with a short neck: lvs. 3-4, appearing with the fls., 1 ft. or more: fl.-st. to 1 ft. high, bearing a 2-10-fl. umbel: fls. bright yellow, about 1 in. long, with a short tube and oblong-lanceolate nearly equal segms; stamens 6, in 2 series: fr. a globose membranous caps., 3-valved; seeds flat. B.M. 7072. Var. *minor*, Baker (*A. luteus*, Baker), is a dwarf mountain form with narrower perianth-segms. These plants are half-hardy in the milder parts if given good protection over winter.

**ANOMATHËCA**: *Lapeyrouisia*.

**ANÓPTERUS** (referring to the seeds being winged at top). *Saxifragaceæ*. Greenhouse shrub, blooming in spring.

Shrubs or small trees, glabrous, with alternate thick evergreen exstipulate lvs., and white fls. in terminal racemes: calyx-tube very short, the lobes 6-9, persistent; petals and stamens as many as calyx-lobes: fr. a caps., oblong-conical, opening by 2 recurved valves, seeds winged at one end.—Two species in Australia and Tasmania.

**glandulösus**, Labill. Handsome evergreen shrub, becoming a small tree (to 40 ft.) in its native regions: lvs. mostly at ends of branches, elliptic-lanceolate to somewhat obovate, 4-8 in. long, somewhat serrate: fls. in somewhat drooping bracted racemes 3-6 in. long; parts of petals usually 6, about ½ in. long. Subalpine Tasmania.

L. H. B.

**ANREDËRA** (personal name). *Basellaceæ*. A monotypic genus, allied to *Boussingaultia*. Vine, with fleshy sts. and lvs., tuberous-rooted: fls. small, white, in long slender mostly axillary spikes; sepals 2, broadly winged; petals 5, not exceeding sepals; stamens 5, the filaments fattened; stigma entire. *A. scandens*, Moq., is native Texas to S. Amer., and planted in Old World tropics, a much-branched vine sometimes cult. in greenhouses, with lvs. ovate and more or less acute, entire.

217. *Anæctochilus regalis*. (× ½)

**ANSÉLLIA** (in honor of John Ansell, African explorer). *Orchidaceæ*. Epiphytic hothouse orchids with tall, thickened leafy stems.

Flowers in panicles, showy; sepals and petals similar, spreading; lip erect, sessile at the end of the column-foot; lateral lobes broad, parallel, erect; middle lobe round-ovate, spreading; pollinia 2.—A genus of 4 closely related species, perhaps all forms of 1 species.

**africana**, Lindl. Sts. up to 2 ft. tall, leafy above: lvs. 4-8 in. long, about 5-nerved, elongated-lanceolate: panicle many-fld.; fls. 2 in. across, with brown-purple spots on a light yellow-green background; sepals narrow-oblong; petals about twice as broad as sepals; lateral lobes of lip oblong, the middle lobe ovate. Fernando Po. B.M. 4965.

**gigantæa**, Reichb. (*Cymbidium Sanderstonii*, Harv.). Differs from the above in the smaller fls. with narrower segms. which are spotted on the lower part only. Natal. B.M. 4965, f. 3.

GEORGE V. NASH. †

**ANSÔNIA**: *Amsonia*.

**ANTENNÀRIA** (pappus likened to antennæ). *Compositæ*. EVERLASTING. CAT'S-EAR. LADIES' TOBACCO. PUSSY'S TOES. Field herbs, sometimes offered by dealers in native plants.

Small, white-woolly perennial plants, with spatulate or obovate root-lvs., and mostly leafless scapes, bearing small gray or white heads which remain stiff and dry: fls. diœcious, the staminate forms rare in cult., all tubular.—None is showy. They are interesting for rock-work and the edges of borders, and for this purpose have been sparingly intro. in the last few years. They are perfectly hardy, and thrive in poor soil. The fls. are often cut before fully mature and dried (and often dyed) as everlastings. About 20 species grow wild. Prop. mostly by division of the mats; also by seeds. Allied to *Anaphalis* and *Gnaphalium*, both of which are leafy stemmed plants quite distinct from the prostrate, stemless antennarias, which send up only a bracted scape, except in *A. racemosa*. See *Everlastings*.

A. *Pappus of sterile fls. not thickened at the tip, minutely roughened.*

**dimôrpha**, Torr. & Gray. Tufted, with spatulate lvs. and a sparsely lvd. fl.-st. an inch or less high, from a stout, much-branched rootstalk. Neb. west to Calif.

AA. *Pappus of sterile fls. thickened at the top.*

B. *Not spreading by stolons.*

**Geÿeri**, Gray. Stout, thick-woolly, from a woody base: fls.-st. 3 in. or more high, very leafy to the top: pistillate heads narrow: involucre with rose-purple or ivory-white tips to the inner scales. Calif. and Ore.

BB. *Spreading by stolons.*

c. *Heads solitary or in a cymose cluster.*

**dioica**, Linn. (*A. candida*, Hort.). Basal lvs. 1½ in. or less long, 1-nerved or only indistinctly 3-nerved: st. 2-12 in.: involucre bracts all light green or light brown, with white or pinkish tips. Northern states and Eu., and Asia.—The plant in the trade as *A. tomentosum* is probably a form of this species. Also in cult. under the proper name, *A. dioica*. *A. hyperborea*, Hort., a name common in the trade, is apparently a mere form of this with pinkish fls.

**alpina**, Gaertn. Plant 1-4 in.: involucre bracts in fertile heads, dark brownish green, acute. Canada, Rocky Mts., Sierra Nevada.

**plantaginifolia**, Rich. Basal lvs. 1½ in. or more long, distinctly 3-nerved: st. 6-18 in. high.—Stoloniferous, making broad patches. Common in fields and old pastures. Perhaps not in cult.

CC. *Heads loosely nerved.*

**racemosa**, Hook. Light-woolly, the flowering sts. 6-20 in. high, sparsely leafy, the heads mostly on slender

peduncles: involucre brownish, white-tipped. Ore. and Brit. Col. to the Rockies.

*A. margaritacea*=*Anaphalis margaritacea*.

N. TAYLOR. †

**ÂNTHÉMIS** (Greek name of the chamomile). *Compositæ*. CHAMOMILE. Pyrethrum-like heavy-scented plants, annual, biennial or perennial, members of a

218. *Anthemis tinctoria*. (×¼)

large, Old World temperate-region genus, used in borders and alpine gardens.

Heads many-fld., the disk yellow, the rays white and yellow and (in the common cult. species) pistillate, the receptacle conical and chaffy, the achenes terete or ribbed, and either naked or bearing a minute crown: lvs. pinnately dissected.

Two or three of the species are weeds. Others are excellent border plants. The true chamomile is a medicinal plant. The hardy perennial species, which alone are grown in this country, are easily handled in the border, where they bloom from midsummer till frost. They thrive in almost any soil, but need full exposure to sun.

Propagation is by seeds or division of the clumps, usually the latter.

A. *Rays normally yellow.*

**tinctoria**, Linn. GOLDEN MARGUERITE. Fig. 218. Of bushy habit, 2-3 ft., with angular st. and pinnately divided, and again pinnatifid or cut-toothed lvs., and large, daisy-like golden yellow fls. (1-2 in. across). Gn. 42, p. 91; V. 18:33. *A. Kélmayi*, Hort. (or var. *Kélmayi*, Hort.), has finer-cut foliage and deeper yellow fls. There is also a pale-rayed variety and a white-fld. form is sold under the name *A. montana*. Gn. 52:484.—An excellent hardy perennial border plant, and useful at the same time for cut-fls.

AA. Rays white.

B. Perennial; cult.

*nobilis*, Linn. CHAMOMILE. Half-spreading and much-branched herb, downy, the lvs. very finely dissected: pappus wanting, chaff of the receptacle blunt. Var. *grandiflora*, Hort., is larger-fl. than the

type, and sometimes yellow-fl. —A pleasant-scented herb, sometimes escaped from cult. It yields the medicinal chamomile fls. of commerce. For medicinal purposes, the heads (the single preferred) are cut as soon as fully expanded, and dried. Cult. also as a hardy border plant; often double.

BB. Biennial or annual; weeds.

*arvensis*, Linn. Pubescent, not ill-scented: lvs. rather coarsely 1-2 pinnately parted: pappus a minute border: heads 1 in. or more across; the involucre with broad, blunt scarious marginal edges; rays pistillate, spreading, 2-toothed. —Not common and rather coarse.

*Cótula*, DC. MAY-WEED. DOG FENNEL. Fig. 219. A common

weed along roadsides, ill-scented, growing 1-2 ft. high, with finely dissected lvs., neutral rays and many asterlike fls. 1 in. across.

*A. Aizdon*, Griseb. = *Achillea ageratifolia*. Gn. 24:342. — *A. arabica*, Linn. = *Cladanthus*. — *A. coronaria*, Hort. = *Chrysanthemum coronarium*. — *A. floribunda*, Hort. Dwarf: lvs. much dissected: fl.-heads pure white. — *A. Biebersteiniana*, Koch, is found in some catalogues. It is an alpine plant with pinnate lvs., which are silvery, and yellow fls. Can be cult. only in the alpine garden.

L. H. B.  
N. TAYLOR.†

ANTHER: Flower.

**ANTHÉRICUM** (Greek, *flower hedge*). Includes *Phalangium*. *Liliaceæ*. Non-bulbous liliaceous plants grown in borders and cool greenhouses.

Herbs, with tuber-like rhizomes, and racemes of rather small, white, deep-cut fls.: perianth rotate; anthers attached between their basal lobes, and the locules many-ovuled—in these characters differing from *Paradisæa*.—Some 50 species, mostly African, but a few in the western hemisphere.

The anthericums are useful for lawn vases, for borders that are protected in winter at the North, for greenhouses and also for growing under benches. Propagation naturally by stolons; increased also by division and seeds. Of easiest culture. Give plenty of water when in bloom.

*Liliago*, Linn. ST. BERNARD'S LILY. Figs. 220, 221. St. simple, 2-3 ft. high, bearing an open raceme of open-spreading fls. 1 in. or less across, the segms. linear-oblong: lvs. long and narrow. S. Eu. and N. Afr. B.M. 914. Var. *majör*, Sims, is larger in all its parts. B.M. 1635.

*ramdsum*, Linn. St. branched: fls. somewhat smaller. Eu. B.M. 1055

*A. Bichetii*, Hort. Lvs. flexible, variegated with white; elegant habit. W. Trop. Afr. — *A. californicum*, Hort. = *Chlorogalum pomeridianum*. — *A. Höfmannii*, Engler. Free-flowering: lvs. 1 ft., 1½ in. broad, shining green: fls.-sts. scarcely exceeding the lvs.: fls. in dense panicles, star-shaped, white. E. Afr. — *A. Liliastrum*, Linn. = *Paradisæa Liliastrium*. — *A. picturatum*, *A. variegatum* and *A. vittatum* are garden names for *Chlorophytum elatum*.

L. H. B.

**ANTHOLYZA** (name from the Greek, referring to fancied shape of flower). *Iridaceæ*. Cormous plants of the gladiolus kind, grown in the open for summer bloom; red and yellow.

Perianth long-tubular, curved, dilated above, the uppermost segms. largest; stamens 3; style branched; ovary 3-loculed. — About 14 or more Cape and Trop. African plants, with linear or sword-shaped lvs. and bright fls. in 2-sided spikes. Cult. the same as gladioli, being taken up in the fall. The tubers are often started in a frame or in the house before planting in the open.

AA. Perianth red; segms. very unequal.

*Cunônia*, Linn. Corm small, globose: st. simple, 1-1½ ft.: lvs. about 4, linear, 1 ft. or less long: fls. 4-6, in a lax spike, bright red, tube an inch long, the stamens reaching to the tip of the upper segm.: seeds discoid, winged. Cape. L.B.C. 20:1971 (as *Anisanthes*).

*cáffa*, Ker. Corm large, globose, long-necked: st. 2 ft. or less: lvs. narrow-linear, 1 ft.: fls. 12-20, in a lax spike, bright red, tube 1-1½ in. long, stamens not quite reaching tip of upper segm.: seeds 3-angled, narrowly winged. Cape. — Has been hybridized with gladiolus.

AA. Perianth red and yellow; segms. less unequal.

*æthiópica*, Linn. (*A. ringens*, Andr.). Corm large, globose: st. branched, 3-4 ft.: lvs. several, sword-shaped, 1 in. broad and 1-1½ ft. long: spikes 6-9 in. long, rather dense; fls. 1½-2 in. long, red-yellow; stamens reaching to the tip of the upper segm.: seeds turgid, not winged. Cape. B.M. 561. Var. *minor*, Lindl. (*A. bicolor*, Gasp.). Dwarf: lvs. narrow: fls. red at top, pale yellow below. B.R. 1159. Var. *vittigera*, Baker, (var. *ringens*, Nichols.). Tall as the type: fls. bright yellow, striped red. B.M. 1172. Var. *immarginata*, Baker. Fls. red, with dull yellow.

*paniculata*, Klatt. Corm large, globose: st. stout, much branched, 3-4 ft.: lvs. lanceolate, oblique, 2 ft. or less long, to 3 in. broad: spikes dense, many-fl., with wavy rachis; fls. bright red-yellow, tube curved, to 1¼ in. long, upper segm. ligulate. Natal. Var. *majör*, Hort. A form with larger lvs. and fls.

*crocosmioides*, Hort. Said to be a hybrid of *A. paniculata* and *Crocsmia*: 3 ft.: spikes branching; fls. brilliant orange-red, shaded to gold.

*A. abyssinica*, Brongn. Corm globose, 1 in. diam.: st. 2 ft. or less: lvs. 3-4, linear, 1 ft. long: spike simple, few-fl.; fls. bright red, the curved tube 1 in. long. Abyssinia. — *A. quadrangularis*, Burm. (Gladiolus quadrangularis, Ker.). Corm large, globose, plant stoloniferous: st. slender, 2-3 ft.: lvs. 2-3, narrow: spike very lax, 2-4 fl.; fls. bright red and yellow, tube 2 in. long. Cape. — *A. Schweinfurthii*, Baker. St. terete, 1 ft. to spike: lvs. 5 to 6, grass-like, 6 in. long: spike simple and lax, many-fl.; fls. bright red shading to yellow, about 1½ in. long, the tube curved and dilated. Abyssinia. B.M. 7709.

L. H. B.

220. *Anthericum Liliago*.

219. *Anthemis Cotula*. (× ½)

**ANTHOXÁNTHUM** (Greek, *anthos*, flower, and *xanthos*, yellow). *Gramíneæ*. Aromatic grasses with spike-like panicles. Spikelets with 1 awnless perfect floret, and two 2-lobed, awned sterile lemmas. Species 4, Eu. A perennial species, sweet vernal grass (*A. odoratum*, Linn.), is occasionally cult. as a meadow grass to give a pleasant odor to hay. Dept. of Agric., Div. of Agrost., Bull. 20:55. Another species, an annual (*A. Puellii*, Lecq. & Lam.), is more rarely cult.

A. S. HITCHCOCK.

**ANTHRÍSCUS:** *Chervil*.

**ANTHÚRIUM** (Greek, *tail-flower*). *Aráceæ*. Choice hothouse foliage plants.

Perennial, the st. creeping, climbing, assurgent or arborescent: lvs. variable, net-veined, with a prominent midnerve and lateral nerves, and a well-defined nerve at or near the margin: fls. in a spike (spadix), subtended or inclosed in the spathe: fr. a berry. Tropical herbs and climbing plants of perhaps 608 species besides varieties, mostly from the central and warmer parts of S. Amer., though probably not one-tenth are in cult. in this country. Grown either for their showy spathes and spadices, or their handsome velvety lvs. Spathe usually spreading or even reflexed, only rarely partially inclosing the spadix. Differs from *Alocasia* and allied genera in technical characters. Monogr. by Engler in De Candolle's *Monographiæ Phanerogamarum*, Vol. 2 (1879), and *Pflanzenreich*, hft. 21 (1905).

The genus *Anthurium* appears to be a constantly increasing one as regards the number of species. Index Kewensis, when first issued in 1893, gave the number of known species as 213. The supplements have now recognized 365 more species, making in all about 578 known species, though there are probably not more than fifty in cultivation in this country and perhaps not more than ten or fifteen known to the trade. Of those that are in cultivation there are several varieties or hybrids, as the species seem to cross readily.

Anthuriums are tropical aroids of great beauty, and at least a few species should be included in every collection of choice plants. They seem to fall naturally

221. Stolon of *Anthericum Liliago*.

into two sections or groups, viz., foliage and flowering. Although anthuriums all flower, those that have the large handsome velvety leaves, such as *A. crystallinum*, *A. Warocqueanum*, *A. splendidum*, and the like, have very inconspicuous or decidedly unattractive flowers, while *A. Andræanum*, *A. Brownii*, *A. Regnellianum* and *A. Scherzerianum* and many others have remarkably showy, usually scarlet spathes and spadices but much less handsome foliage. All are striking plants.—Anthuriums such as *A. Andræanum*, *A. ornatum*, and their numerous hybrid progeny, require at all

times a high and humid atmosphere. Under these conditions and in a good rooting medium, they ought to be continually in flower. A bloom is produced from the axil of each leaf, and immediately beneath this leaf a new root is produced, thick and succulent at first, becoming tough with age, and, if not allowed to bury itself among the compost in which the plant grows, it eventually hardens and is of no help in the sustenance of the plant.

Therefore, the growing point of the specimens should not be allowed to get too high, or the flowers will be few and poor. When the plant forms stems above the pot, the compost should either be built up around the stem, to catch the roots, or the plant may be cut over, rooted afresh in sand, and given a new start in a pot. The two ornamental-leaved species, *A. Veitchii* and *A. Warocqueanum*, should be treated in the same manner. When cut down, one may look for the old stocks to send out small growths, which in course of time may be taken off and put in small pots. All of the above are such free-rooting kinds that they may, with the addition of some rotted manure, be grown in sphagnum moss. A good mixture is as follows: sphagnum, chopped not too fine, one part; fern or kalmia roots, chopped up and the fine substance removed,

222. *Anthurium Scherzerianum*. ( $\times \frac{1}{2}$ )

one part; another part to be made up equally of sand and rotted manure. With well-drained pots, this forms an admirable rooting substance.—Most of the other species and their forms, including *A. Scherzerianum* and *A. crystallinum*, will thrive better in material mainly composed of rough, fibrous loam and peat with the fine material sifted from it. This rough, fibrous material should be mixed with a small quantity each of sphagnum, charcoal and sand. Good drainage, and less water than is needed for the *Andræanum* and *Warocqueanum* groups will be necessary. *A. Scherzerianum*, although thriving well in the hottest house, will succeed in an intermediate house.—Established plants of anthurium will need repotting only once in two or three years, but should have a fresh top-dressing every year; the best time to overhaul them is about the end of January, or before active growth begins. They should be given a shaded position, free from draughts of cold air, and ordinary stove temperature. Care must be taken not to mar the leaves by hard spraying. The temperature during winter should not fall below 55°.—Propagation is by suckers or cuttings of the rhizome inserted in small pots containing a mixture of peat fiber, chopped sphagnum moss and silver-sand in equal proportions, and plunged in a propagating-box in a temperature of 75° to 80°, with bottom heat. About the end of January is the most suitable time to take the cuttings. Anthuriums may also be propagated by seeds sown in a mixture of very fine fibrous peat and chopped sphagnum moss in 4-inch pots. The seeds should be lightly covered with sphagnum, and the pots placed either in a propagating-case or under bell-glasses, where a temperature of 80° can be maintained. A constant humid atmosphere is very necessary to induce the seeds to germinate. To prevent damping, the seedlings should be pricked off round the edge of a 3-inch pot as soon as the first leaf is large enough to handle. Seeds of such kinds as *A. crystallinum* and *A. regale* will germinate well on the moss of nepenthes baskets.

Seeds are secured by pollinating the flowers, the stigmas of which become mature long before the anthers. Anthuriums of the Scherzerianum type may be increased by division of the crown. (E. J. Canning and G. W. Oliver.)

A. Lvs. plain green: grown mostly for the showy "flowers."

B. Spadix coiled.

1. *Scherzerianum*, Schott. Fig. 222. A foot or two high, evergreen: lvs. long-lanceolate (the blade 1 ft. or more long and petiole of nearly equal length), thick, usually somewhat revolute, with a strong vein parallel with each edge and close to it, and many cross-veins: scape long and slender (1-2 ft.), red; spathe ovate-oblong, 3-4 in. long, spreading or deflexed, intense red (sometimes double, I.H. 37:107); spadix slender, curled, yellow. Cent. Amer. B.M. 5319. R.B. 22:121. Gn. 33, p. 89. G.C. II. 12:301. G. 3:55. A.F. 6:569 (in variety).—An old favorite. Runs into many forms: spathe white, vars. *album*, *album magnificum*, *lacteum*, *maximum album*, *Williamsii*, *Vervænum*; spathe parti-colored, vars. *andegavense* (scarlet on the back, white and scarlet spotted above), *mutabile* (white-bordered), *nebulosum* (double white spotted rose), *Rothschildianum* (scarlet mottled white, Gn. 30:454), *Warocqueanum*, not *A. Warocqueanum* (white spotted red); spathe very large, vars. *giganteum*, *maximum*, *Wardii*, *Woodbridgei*. Very dwarf is var. *pygmæum*; rose-salmon spathe and orange spadix is var. *pariense*; sharp pointed lvs. and spathes is var. *Bennettii*; rose-colored spathes, var. *roseum*; deep blood-red spathes, var. *sanguineum*.

BB. Spadix not coiled.

c. Spathe narrow, green.

D. The lvs. narrow, not cordate.

2. *spathiphyllum*, N. E. Br. Two ft. or less, stemless or nearly so: lf.-blade 2 ft. or less, narrow-lanceolate, attenuate in a straight line from the middle to the base, acuminate, bright green above and grayish beneath,

223. *Anthurium Andræanum*. (× 1/2)

with prominent midrib: spathe 2 in. or less long and a half or more as wide, erect, boat-shaped, pale green or whitish; spadix 1 in. long and very blunt, pale yellow. Trop. Amer.

3. *Regnellianum*, Engl. Lvs. 5-6 in. long, about 2 in. broad, obtuse or slightly emarginate at the base, gradually narrowed to an acute apex, green: spathe

about 1 1/2 in. long, 1/4-1/2 in. broad; spadix dark green, 1 1/2-2 in. long, on a short stipe. Brazil.

DD. The lvs. broad, deeply cordate.

4. *Bröwnii*, Mast. Lvs. 2-3 ft. long, a deep sinus separating the rounded basal lobes, leathery, dark shining green above, paler beneath, with 12-15 pairs of prominent lateral nerves: spathe 6-8 in. long, lanceolate, greenish, rose-tinted; spadix 10-15 in. long. Colombia. G.C. II. 6:744-5.

cc. Spathe cordate-ovate, colored.

5. *Andræanum*, Lind. Fig. 223. Low species, with lf.-blades drooping like an alocasia and cordate ovate-lanceolate: spathe cordate-ovate, thick in texture, 6-10 in. long, orange-red, widely open-spreading; spadix 3-4 in. long, yellowish, with white band marking the zone in which the stigmas are receptive. Colombia. B. M. 6616. A.F. 6:569; 10:1065. Gt. 38:1293. I.H. 24:271; 37:105. V. 9:259; 11:138. G.C. II. 13:497.—Beautiful and popular. Runs into many varieties. Spathes white, var. *album*; spathe very bright red, shining, var. *Gæmeri* (R.H. 1907:30, desc.); spathes very large, pure white, var. *Láwrenciæ*; spathes of a soft rose-color in upper part passing into light green on lateral lobes, var. *rhodochlorum* (R.H. 1901:452); spathes shining rose-pink, var. *roseum*; spathes salmon-color, var. *salmoneum*; spathes dark crimson, var. *sanguineum*.

AA. Lvs. prominently marked with white or colors, or with deep bands of green: cult. mostly for foliage.

B. The lvs. not bullate.

c. Markings green or greenish.

6. *Veitchii*, Mast. Fig. 224. Tall and robust species (st. 2-3 ft.): lf.-blades pendent, like a fine alocasia, often 3-4 ft. long, cordate or eared at base, metallic green, but marked by deep-sunk nerves, which arch off the midrib: spathe 1 ft. long, horizontal, green; spadix 6-8 in. long, straw-color. Colombia. G.C. II. 6:773. B.M. 6968. Mn. 8:187. I.H. 27:406. Gn. 29, p. 453. G.C. III. 44:181.—Striking.

cc. Markings white or essentially so.

7. *Warocqueanum*, Moore. Fig. 225. Very vigorous: lvs. oblong-lanceolate, long-tapering, hanging, 2-4 ft. long, deep velvety green, with rib and principal veins of a prominently lighter shade, making handsome contrasts. Colombia. I.H. 27:392. G.C. III. 44:180.—A handsome and striking foliage plant.

8. *magnificum*, Lind. Lf.-blade deep cordate, oval, 2 ft. long, upper surface olive-green with white nerves; petiole 4-angled: spathe small, oblong, green; spadix green, cylindrical. Colombia.

9. *crystallinum*, Lind. & André. Like *A. magnificum*; differs in petiole terete or only very imperfectly angled, sinus of blade smaller, veins wide-banded and whiter and very regular: lf.-blade ovate-cordate, short, deep velvety green, with the midrib and two consecutive bands crystal white: spathe linear-oblong, acuminate,

224. *Anthurium Veitchii*. (× 1/2)  
Young leaf, not yet showing the arched depressions.

green. Peru. I.H. 20:128. G.C. III. 24:417 (var. *illustre*). G. 21:98. G.W. 15, p. 254.

10. *regale*, Lind. Lf.-blade cordate-oblong, long-cuspidate, 3 ft. or less, at first tinged rose, but becoming dull green and marked with white veins; petiole nearly terete: spathe broad-lanceolate, greenish. Peru.

BB. *The lvs. bullate.*

11. *spléndidum*, Hort. Lvs. large, cordate-ovate, coriaceous, sea-green, glaucous above, bullate, the depressions and nerves brownish. Colombia.

Various horticultural forms and hybrids are in cult. in this country: *A. amabile*. Lvs. soft rose (crystallinum  $\times$  magnificum).—*A. Archiducis Josephii*, Lind. Spathe shining carmine, broadly cordate (Andraeanum  $\times$  Lindenianum).—*A. atropurpureum*, Pynaert. Spathe black-purple, spadix white.—*A. bicolor*, Crousse. Spathe white beneath, above whitish and rose-colored. R.H. 1904:40.—*A. carneum* is a hybrid of Andraeanum and ornatum.—*A. Chantiniæ*, Mart. Spathe rose, with paler nerves.—*A. Chantrieri*. Lvs. triangular, with wide-spreading basal lobes: spathe ivory-white, erect (nymphæfolium  $\times$  subsignatum).—*A. chelseiense*, N. E. Br. (Andraeanum  $\times$  Veitchii). G.Z. 31, p. 169.—*A. Clarkianum*. Lvs. large and broad: spathe resembling that of Andraeanum but salmon-rose.—*A. ferrierense*. Lvs. large, cordate: spathe cordate, brilliant red (ornatum  $\times$  Andraeanum).—*A. floribundum*, Lind and André= *Spathiphyllum floribundum*. I.H. 21:159.—*A. Fræbelii*. Lvs. large and cordate: spathe deep carmine (Andraeanum  $\times$  ornatum).—*A. grande* = *A. magnificum*.—*A. Hrúbyi*, Hort. Spathe flesh-colored or almost white.—*A. hybridum*. Lvs. large, lobed at base, obtuse, green.—*A. musaicum*.—*A. ornatum*. Lvs. oval or oblong, cordate: spathe linear-oblong, white, purple-tinted.—*A. Reynoldsianum*, various forms (ferrierense  $\times$  Andraeanum?).—*A. Siebrechtianum*. Lvs. much as in *A. magnificum*, rich, velvety green, with thick margins: spathe light green shading to cream; spadix large, crimson.—*A. triumphans*. Lvs. long-heart-shaped, bright green with lighter veins: spathe narrow, green; spadix greenish white.

*A. acule*, Schott. Fls. fragrant: lvs. 1-2 1/4 ft. long, very broad. W. Indies.—*A. acutum*, N. E. Br. Lvs. 8-10 in. long, triangular and long-acuminate, green: spathe reflexed, green; spadix deep green. Brazil.—*A. Allendorffii*=Andraeanum  $\times$  Grusonii.—*A. Bakeri*, Hook. Lvs. elliptic-lanceolate or linear, green: spathe small, reflexed, green; spadix 3 in. long, yellowish green, becoming longer and red and drooping in fr.—the chief merit of the plant. Costa Rica. B.M. 6261. G.C. III. 29:2.—*A. bogotense*, Schott. Lvs. with a very broad halberd-shaped base and a long-acuminate middle lobe, dark green. Gt. 46, p. 525.—*A. brevifolium*, N. E. Br. Lvs. oval-acuminate, cordate, 8-10 in., paper-like, green: spathe lanceolate, purplish: spadix purplish brown.—*A. carneum*, Hort. Chant. Spathe a beautiful rose color.—*A. Chamberlainii*, Mast. Lvs. 4 ft. long, broadly cordate-ovate and narrowly long-pointed, green: spathe erect, boat-shaped, 8-9 in. long, purplish outside, crimson inside, partially inclosing the purplish spadix. Venezuela. G.C. III. 3:465. I.H. 35:62. B.M. 7297.—*A. Clémentinae*, DeSmet. Spathe white

225. *Anthurium Warocqueanum*.

with rosy nerves.—*A. coriáceum*, Endl. Lvs. very thick, leathery, 2 ft. long. Brazil.—*A. Eduardii*, Pynaert. Spathe white (Andraeanum  $\times$  Lindenianum).—*A. Forstii*, N. E. Br. Related to *A. crystallinum*, but smaller and with petate lvs. of a deep rich green with a velvety sheen, the veins not quite so marked. Colombia.—*A. Glaziovii*, Hook. Lf.-blade obovate-oblong, not hanging; tapering to petiole, green and strongly light-veined: spathe linear-oblong, often twisted, purple (as is also the spadix). Brazil. B.M. 6833.—*A. grandiflorum* var. *perfectum*, Hort. Spathe very large, of a pronounced red color.—*A. Gustávii*, Regel. Lvs. broadly ovate-cordate, bright green: spathe cylindric, about 1 ft. long, and dark violet-purple like the spadix. Colombia. B.M. 7437.—*A. Hardyæ*, Mart. Spathe rose, spadix white.—*A. Hookeri*, Kunth. Lvs. dotted with black, spathe lanceolate. B.M. 2987 (as *Pothos crassinervia*). W. Indies.—*A. insignis*, Mast. G.C. II. 6:365.—*Philodendron tripartitum*.—*A. Kalbreyeri*, Hort. Climbing: lvs. 9-parted. Colombia. G.C. II. 16:117.—*A. Laucheanum*, Hort., Sand. Resembles *A. Andraeanum*, but lvs. reticulated: sts. climbing. Colombia. G.C. III. 43:258.—*A. Lindenianum*, Koch & August. Lvs. ovate-cordate, green, coriaceous: spathe pure white, linear-oblong, 5-6 in. long; spadix dark purple. Colombia. B.M. 5848. F.M. 1876:236 (both as *A. ornatum*).—*A. Miquelianum*, Koch. St. climbing: lvs. shining, elliptic-oblong, 1-2 ft. long: spathe lanceolate, green. Brazil. G. 7:435 (as *A. ornatum*).—*A. Nicolaiæ*, Engl. Spathe yellowish, flushed with rose.—*A. nymphæfolium*, Koch. Spathe white; spadix purple. Venezuela.—*A. purpureum*, N. E. Br. Lvs. oblong-lanceolate, thick, green: spathe and spadix purple. Brazil.—*A. rotundispatheum*, Lind. & Rod. Spathe nearly round, intensely sanguineous.—*A. Sanderi*, Hort. R.B. 34, p. 196.—*A. signatum*, Koch. Lvs. 3-lobed, deep green. Venezuela.—*A. trifidum*, Oliver (B.M. 6339)=*A. signatum*.—*A. trinerve*, Miq. Climbing: lvs. oblong-elliptic, 4-7 in. long: spadix up to 2 in. long, 3/4 in. thick in fruit: berries lilac. S. Amer. B.M. 8251.—*A. watermaliense*, Hort. Allied to *A. Andraeanum*. Spathe of a metallic black. Colombia. Intro. from Watermall, Belgium.

L. H. B.

GEORGE V. NASH.†

**ANTHÝLLIS** (Greek, meaning *downy flowers*). KIDNEY VETCH. *Leguminosæ*. Perennial herbs, or somewhat shrubby, prized for their spikes or heads of yellow, purple or white flowers and usually silky pinnate foliage; also for forage; in the Old World, prized mostly for rockwork.

Calyx-tube inflated near the base, dentate or lobed above; petals pea-like; the stamens all connected into a tube: legume usually ovoid.

The culture is the easiest, as the plants thrive even in poor soil. Propagation is by seeds or division, or, rarely, by soft cuttings. Not generally known in United States.

A. *Lfts. 4 or more pairs.*

**Vulneraria**, Linn. SAND CLOVER. WOUNDWORT. A foot high: lfts. 5 or more: fls. normally yellow, but there are red and white varieties. Eu.—A deep-rooted, clover-like, hardy plant, excellent for sandy and light lands. Useful for forage, and, for that purpose, occasionally grown in this country. Requires 20 lbs. of seed to the acre. See Cyclo. Amer. Agric., Vol. II, p. 308 and fig. 416.

**montana**, Linn. A foot or less high, silky-hoary: lfts. numerous: fls. purple in dense heads subtended by a leafy involucre. Herbaceous. Var. *rúbra*, Hort., is a reddish fld. form suitable for rock-gardens. Eu. L.B.C. 6:578.

**Bárba-Jóvis**, Linn. JUPITER'S BEARD. Glasshouse silky evergreen, 3-8, or even 12 ft. high, with several to many pairs of narrow, pointed lfts.: fls. straw-colored or whitish, in clover-like heads. S. Eu. B.M. 1927.—In frostless countries, endures sea-winds and salt spray.

AA. *Lvs. unifoliate or trifoliate.*

**Hérmannia**, Linn. Two to 4 ft.; dwarfier and more bushy than the preceding: lvs. almost sessile, simple or trifoliate, the lfts. oblong-cuneate: fls. yellow in axillary almost sessile, few-fld. heads. S. Eu. B.M. 2576.—Good for dry places. Intro. by Franceschi in 1910. N. TAYLOR.†

**ANTIARIS** (name derived from Greek word for *arrow*, the sap being used for arrow poison.) *Moracæ*. Five or 6 trees or shrubs of the E. Indies and Malaya famous because of the upas-tree, *A. toxicaria*, Lesch., fabled for years to be so poisonous that men or animals were destroyed who came within some distance of it. These

legends are apparently Javan. The tree has been grown in botanic gardens, however, with no disastrous results. The dried milky juice is very poisonous, and the natives use it with other ingredients (the ipoh poison) for poisoning arrows. The tree grows 60–70 ft. high, with alternate distichous short-std. oblong or oblong-ovate, entire lvs. and monoecious fls., the sterile fls. in dense heads and the fertile fls. solitary; fr. a 1-seeded fleshy drupe. A fiber is yielded from the inner bark. Another species, *A. innoxia*, Blume, yields fiber that is used for the making of sacks.

**ANTIDÉSMA** (Greek, *for* and *band*, the bark of *A. Bunius*, being used for cordage). *Euphorbiaceæ*. Tropical trees rarely cult. Lvs. large, alternate, simple: fls. small, in spikes; calyx imbricate; petals none; ovary 1-celled, 2-ovuled. The 1 species cult. for its currant-like berries used in preserves. The very tough fiber of the bark also used. The tree is very ornamental and suited to the subtropical parts of this country. Prop.

226. *Antigonon leptopus* var. *albus*. ( $\times \frac{1}{5}$ )  
From a plant grown under glass.

by cuttings. There are about 70 other species in the warmer parts of the Old World.

**BUNUS**, Spreng. NIGGER'S CORD. SALAMANDER TREE. CHINESE LAUREL. BIGNAY of Malays. A medium-sized evergreen tree with dark green laurel-like foliage, and small red berries in racemes. Malay region.

Two similar shrubs, *A. nitidum*, Tul., from Malaya, and *A. venosum*, Mey., from S. Afr., have been intro. by U. S. Dept. of Agric.

J. B. S. NORTON.

**ANTIGONON** (name from Greek, probably referring to the kned or angled character of stem). *Polygonaceæ*. Showy-flowered climbers, abundant in southernmost United States and southward, and sometimes grown in warmhouses.

Tropical tendril-climbers: sepals 5, colored petal-like and cordate, the 2 interior ones narrower; stamens 8; styles 3, and ovary 3-angled: lvs. alternate and entire: fls. in racemes, which end in branching tendrils. —Species 3 or 4, in Mex. and Cent. Amer.

The usual species is *A. leptopus*, one of the most conspicuous and beautiful climbers grown in Florida, and always in flower from early spring to late autumn. It grows 30 to 40 feet high in good soils. Some plants are shy bloomers, while others are often covered from top to bottom with a mass of bright deep rosy red. Too much fertilizer effects a very vigorous growth at the cost of the flowering. Verandas covered with antigonon look extremely beautiful, and cabbage palmettos decorated with masses of its pendent flower-trusses

form charming objects. The plants form large tubers and when killed down by frost, sprout readily again in spring. Seeds, looking much like buckwheat, are abundantly produced and form a ready means for propagation. Small plants from self-sown seeds come up everywhere in Florida gardens. (H. Nehrling.)

**léptopus**, Hook. & Arn. MOUNTAIN ROSE. ROSA DE MONTANA. SAN MIGUELITO. CORALLITA. LOVE'S CHAIN. Plant tuberous-rooted: st. slender and tall, glabrous, or nearly so: lvs. cordate and acuminate, or hastate-ovate, 3–5 in. long: fls. 6–15 in the raceme, handsome rose-pink. Mex. B.M. 5816. G.C. III. 17:797. Gn. 68, p. 320. G.M. 49:317. Var. *álbus*, Hort. (Fig. 226), has fls. nearly or quite white.—One of the handsomest summer-blooming greenhouse climbers, requiring abundance of light and recommended to be planted near heating-pipes and to be trained on the rafters; usually grown from seeds, but also from cuttings. Give plenty of water when in flower but keep dry when at rest. In the S. and the American tropics it is one of the commonest vines on fences, arbors and verandas.

*guatemalense*, Meisn. (*A. insigne*, Mast.). Pubescent: lvs. broader: fls. more numerous, the sepals nearly twice longer (1 in. long) than in the last. Guatemala. G.C. II. 7:789.

L. H. B.

**ANTIRRHINUM** (Greek, *snout-flower*). *Scrophulariaceæ*. SNAPDRAGON. Flower-garden and greenhouse herbs.

Erect or climbing herbs or even half-shrubs: lvs. usually opposite below and commonly entire, never compound: corolla saccate or gibbous at base, but not spurred, personate or closed at the throat; stamens 4: seeds not winged.—Closely allied to *Linaria*, from which it differs in the spurless fls. About 30 or 40 species in the northern hemisphere, particularly in N. Amer.

Snapdragons are flowered either in the open or under glass. The common varieties are forms of *A. majus*, and are perennial, although the first crop of bloom is usually the only one that is desired. Most of the varieties of this species are hardy in the North, if well covered during winter. Seeds sown very early in the spring, especially under frames, and transplanted, produce blooming plants the same season. It is usual, however, if early bloom is desired, to sow the seeds in August or September, and cover the plants with a mulch on the approach of cold weather. These fall-sown plants may be transplanted into pots (or grown in them from the first) and flowered in the house. For growing under glass in this way, snapdragons are very satisfactory. The temperature and treatment required for geraniums and carnations suit them well. Dwarf varieties are used for edgings.

A. Plant erect, herbaceous.

B. Root annual: small-fl'd.

**Oróntium**, Linn. SMALL SNAPDRAGON. Fig. 227. A low, slender annual, with linear lvs. and small fls. purple or white ( $\frac{1}{2}$  in. long) in the axils. An occasional weed in cult. grounds, 6–12 in. high; not cult.

**Orcuttianum**, Gray. Slender, 2–4 ft., glabrous: corolla  $\frac{1}{2}$  in. long, white or violet, lower lip not much larger than the upper: lower lvs. spatulate-lanceolate, the upper linear. Lower and S. Calif.—Intro. by Orcutt in 1891. Tendril-like branchlets are produced in the fl.-clusters.

BB. Root perennial: large-fl'd.

**majus**, Linn. COMMON or LARGE SNAPDRAGON. Fig. 228. Perennial, or practically a biennial under cult.: 1–3 ft., not downy except in the fl.-cluster: lvs. oblong or lanceolate, entire, sometimes variegated: fls. large,

long-tubular, with spreading, very irregular lobes, in an elongated terminal spike or raceme. In many colors and varieties (ranging from red and purple to white), in forms both tall and dwarf. *Medit. region*; sometimes running wild about gardens. A.F. 9:909; 13:949. I.H. 41:22. A.G. 17:379. F.E. 7:711.—There are double

forms. Some of the varietal names used by horticulturists are *album*, *bicolor*, *coccineum*, *procerrum*, *pumilum*, *variegatum*. Peloric forms are reported, with regular corolla and the much-reflexed limb 5-7-lobed. Gt. 53:1524.

AA. *Plant erect, perennial and shrubby; fls. about 1 in. long.*

**speciosum**, Gray. Three to 4 ft., somewhat pubescent, leafy: lvs. oval or oblong, short-petioled, thick: fls. scarlet or pink-red, the corolla-tube three times length of the lips (which are narrow). S. and Lower Calif., on the islands.

AAA. *Plant trailing or procumbent, perennial, with small fls.; used mostly in rock-gardens. June, July.*

**Asarina**, Linn.

Grayish-clammy, procumbent: lvs. 5-lobed, cordate, crenate, long-petioled: fls. axillary, solitary, white and sometimes tinged red, the palate yellow. S. W. Eu.

**sempervirens**, Lapeyr. Procumbent, woolly, small: fls. white with purple blotch. Pyrenees.

**glutinodsum**, Boiss. & Reut. Prostrate, glandular-pilose: lvs. alternate, elliptic to elliptic-ovate, short-petioled: fls. pale yellowish white, the lip striped red. Spain. B.M. 7285.

AAAA. *Plant climbing, perennial.*

**maurandioides**, Gray (*Maurandia antirrhiniflora*, Willd.). Fig. 229. Climbing 2-6 ft. by means of the coiling petioles and peduncles: lvs. 3-lobed, halberd-shape: fls. axillary, 1 in. or more long, violet or purple, handsome. Texas to Calif. B.M. 1643.—Attractive plant for the window, cool greenhouse or conservatory. Suitable for baskets. L. H. B.

**ANTRÔPHYUM** (Greek, *growing in caverns*). *Polypodiaceæ*. A genus of simple-lvd. herbaceous ferns, rarely found in cult. Native in tropics, in damp forests. All the species are epiphytes, and not of commercial value except as rarities. Require high temp.

**ANTS, Their Habits, Activities, Injuries and Control.** Various kinds of ants are troublesome to gardeners; and all the ants are most interesting animals.

The ants belong to the same great group of insects (Hymenoptera) that contains the wasps, bees, sawflies, and others; and like the honey bee and common wasps are congregate in their habits of living. The abdomen of all the common ants is attached to the thorax by a

slender waist, or peduncle; and each segment (there may be one or two) of this peduncle is expanded on the top side and forms a lens, or button-shaped knot, a character that distinguishes ants from all other insects.

Everyone is familiar with ants; they occur in all lands and all regions, from the dry deserts to the damp forests, from the timber line of mountains to the lowest valleys and among the dwellings and habitations of man. They seem to thrive in all kinds of environment and multiply enormously, so that they outnumber all other terrestrial animals.

*The nature of an ant colony.*

Ants are social; that is, they live in colonies or communities where every individual ant works for the good of the whole and not for itself alone. A colony of ants furnishes an illustration of a more perfect communistic society than any ever established by man, and perhaps a more amicable one than any he will ever be able to organize.

In a typical colony of ants, there are at least three kinds of individuals, the queen, the males, and the workers. The queen is not the ruler but the mother of the colony. Her only business seems to be to lay eggs which hatch into workers and other forms to take the places of those that disappear or die, thus maintaining the full and continuous strength of the community. When the queen comes forth from the pupal stage, she has wings which she retains until after the swarming period. After the swarming flight is over and the queen alights, her wings fall off or are torn off by herself or workers and from that time she remains wingless. In some species of ants there may be modified forms of the queen, for example, giant queens, dwarf queens, worker-like queens, and other forms.

The males, which have wings, exist only to mate with the queens, and after the swarming period is over they eventually die. The males are also often modified into giant males, dwarf males, worker-like males, and other forms.

The workers, which are undeveloped females, are wingless and constitute the great majority of individuals that we see running about in the vicinity of an ant-nest. The workers are just what their title implies. They do the work of the community, build the nest, keep it clean, care for and procure food for the queen and larvae, care for the eggs, fight the battles, and so forth. The workers may exist under several different forms. One especially interesting form has a very large head and strong jaws, thus fitting it for war-like functions. Ants of this form are known as the soldiers.

*The nests and activities of ants.*

The nests of ants, in a general way, consist merely of a system of passageways or cavities communicating with each other and connected to the outside world with one or more openings. There are some species of ants that live below the surface of the earth and have no openings from their nests into

227. *Antirrhinum Orontium*. ( $\times \frac{1}{2}$ )

228. Young spike of a dwarf form of *Antirrhinum majus*. ( $\times \frac{1}{2}$ )

the air, except at the swarming period. The style of construction and the materials used by ants in making their nests vary with the different species and with the environment in which the animals live. Moreover, the nests are very irregular, especially when compared with those of wasps and bees.

The passageways of the nests are enlarged here and there into comparatively large cavities, or chambers. It is in these different chambers that the activities of

229. *Antirrhinum maurandoides*, in bud.  
( $\times \frac{1}{2}$ )

the colony are conducted. The queen lies deep within the interior of the nest in a dry, dark chamber. Here she is carefully tended and fed by the workers who bear the eggs as they are laid, to other chambers and zealously care for them. Many insects never see their young;

others may see them but do not care for them; others, like the bees and wasps, put food into the gaping mouths of their young but have no further association with them. The ants, however, stand alone among insects in their very intimate relations with their progeny from the egg to the adult. Some of the chambers in the nest are reserved for the eggs, some for the larvæ, and some for the pupæ. If, as often happens, the eggs, larvæ and pupæ are all in one chamber, then they are each grouped by themselves in separate piles, reminding one, as Lubbock says, "of a school divided into five or six classes." In the simpler and more primitive ants, this grouping and separation may not be so distinct. The ants are constantly transferring their young from one part of the nest to another in search of the right degree of moisture, temperature, and the like. In the warm part of the day, the young will be transferred to near the surface but at night will be carried down again away from the cool air. The ants are constantly cleaning the young, caring for the eggs to prevent mold from growing on them, helping the callow ants to emerge from their cocoons, bringing food, cleaning, enlarging and reconstructing the nest and doing thousands of things contributing to the comfort, growth and happiness of the community.

#### *The relation of ants to plants and to insects.*

It has been argued and many observations have been offered to show that there is a most intimate relation between ants and many kinds of plants. Certain observers think that many plants not only offer special inducements to attract ants to them by affording favorable nesting-places, but also offer the ants delectable food in the way of a sweet liquid, the floral and extrafloral nectar. In return for the domiciles and the food, the ants are supposed to protect their plant hosts from certain insect and other animal enemies. In other words, the relationship is one of mutual benefit, or a symbiotic one. It is certainly true that many species of ants make their homes in the hollow stems of plants, in the thorns of acacias which the ants easily hollow out (see *Bull-horn Acacias*), in cavities in bulbs, leaves, and so on, and in the dried seed-pods of plants. It is also true that ants assiduously collect and carry to their nests the sweet nectar excreted by many plants. It is not so clear, however, that these favorable nesting-places and the nectar are provided by the plants on purpose to attract the ants, nor is it clear that the ants afford the plants protection from their animal enemies.

In other words, more definite proof is needed to show that the relation between ants and plants is a purposely mutual one.

On the other hand, the relation of ants to plant-lice, tree-hoppers and certain scale insects is clearly, in many cases, a mutually helpful one. Especially is this true of the relations between ants and plant-lice. The aphids secrete a sweet liquid material known as honey-dew, of which the ants are very fond and which they are active in collecting and carrying to their nests. It can hardly be supposed that the aphids excrete the honey-dew solely for the ants. The liquid is an excretion from the alimentary canal and is exuded whether ants are in attendance or not. On the other hand, ants are very solicitous in their care of aphids in return for the honey-dew. The ants sometimes build "sheds" over the lice for their protection and sometimes take the lice into their own nests to care for them. In the case of the corn-root louse, the ants collect the eggs of the aphid in the fall, carry them into their own nests, and care for them all winter. In the spring, the newly-hatched aphids are carried out by the ants and placed in burrows dug beforehand among the roots of certain early food-plants. Later, the ants excavate burrows along the roots of the corn and transfer the aphids to these plants.

It is interesting to watch the ants collecting the honey-dew from the aphids. An ant approaches a louse and gently strokes the latter with its antennæ, whereupon the aphid exudes a drop of the sweet material which is quickly gathered up by the ant. This action may be repeated with three or four of the aphids until the ant has all it desires, when it hurries down the stem of the plant and away to its nest with its load of sweet provender.

#### *The life-history of ants.*

Enough observations have now been made to enable us to say that most, if not all, colonies of ants are started by a solitary queen or occasionally by two queens working together. The queen, after the swarming period, alights, breaks off her wings, and digs a burrow in the soil or in decayed wood, forms a small chamber, and then closes the opening. Here she remains until her eggs are laid and have hatched into small larvæ that finally mature into normal but diminutive workers. All this time the queen has taken no food but has lived and fed the first workers on the reserve material in her body. The small workers now begin to enlarge the nest and soon other larger workers are reared and the community begins to multiply and increase.

The eggs laid by the queen are small and white and rarely seen by the ordinary observer. These are solicitously cared for by workers and finally hatch into white, footless, soft, grub-like larvæ. The larvæ are also tenderly cared for by the workers and changed from chamber to chamber in conformity with variations in temperature and moisture. The workers feed the larvæ either on food which has been predigested and which the workers now regurgitate, or on bits of dead insects, leaves, or seeds that have been chewed fine. The larvæ finally, after attaining their growth, change to whitish pupæ which, in some species, are inclosed in cocoons, while in others they are not. These the workers treat with the same solicitude and care that they show toward the larvæ. The pupæ are often mistaken for eggs. Often, on raising up a flat stone, one will see the workers running this way and that with the larvæ and pupæ in their jaws, evidently seeking a place of safety for them. The pupæ finally transform to the adult ants of the various forms, workers, queens, and males.

#### *Economic importance of ants.*

Ants, as a whole, may probably be considered as agents in making the earth more habitable for man,

Some of the species are neutral, perhaps, in relation to the economic status of mankind. A great many species are certainly beneficial through their action in stirring and aerating the soil. They are constantly burrowing deep into the earth and bringing up the particles which they distribute over the surface. Their action in this respect is similar to that of earthworms, the value of which was revealed to us by the classic investigations of Darwin. Ants are also important agents in aiding in the decomposition of organic substances. Their work in this respect is little appreciated or realized because it is invisible. It must be remembered, however, that this work of ants is gradual, incessant, and extends through tremendously long periods of time.

Again, ants are great insect-destroyers. Their food consists, in great part, of the juices and tissues of dead insects or insects that they kill. The interesting driver ants of the Old World and the legionary ants of tropical Africa pass through a territory killing and devouring multitudes of living insects, rats, mice, and the like. Hunter and Hinds tell us that there are twelve species of ants known to attack the immature stages of the Mexican cotton boll-weevil. "In some cases more than half of the immature stages in fields have been found to be destroyed by ants alone. To find 25 per cent so destroyed is not a rare occurrence."

On the other hand, certain household species of ants are very annoying and troublesome. Moreover, the leaf-cutting ants of tropical America are very injurious to plants. They will strip a fruit tree of its foliage in a very short time. One species of these leaf-cutting forms (*Atta texana*) found in Texas, attacks cotton, corn, fruit trees, sorghum and other plants, and has become of considerable economic importance. In some places, land is not planted on account of fear of attack by these ants.

The mound-building prairie ant (*Pogonomyrmex occidentalis*), distributed over a large part of the western plains of the United States, has become a distinct pest since man has begun to occupy the prairies. Its large mound-nests in fields of alfalfa or grain become serious obstacles to harvesting the crops. Moreover, when the nests are disturbed, the ants emerge in large numbers and attack man and beast, inflicting painful wounds with their stings. In dooryards and lawns and along paths, they are liable to attack the passerby, especially dawdling children.

The agricultural ant (*Pogonomyrmex barbatus molefaciens*) of Texas may build its mound-nests in fields of alfalfa, corn, or cotton, and, since it allows no vegetation to grow over a considerable area around the nest, the injury may be serious. Moreover, they are pugnacious and sting intruders severely.

Perhaps the most injurious rôle assumed by ants is their protection and fostering of plant-lice, scale insects, and the like. Aphids and scale insects are among the most injurious insect pests, and anything that protects them or aids them in increasing may be considered an enemy to man.

As a pest, the Argentine ant (*Iridomyrmex humilis*), stands by itself. Professor Newell says, "As a household pest I venture the opinion that this ant has no equal in the United States." Unfortunately, it has also become a serious menace to horticultural interests as well. It destroys the buds, blossoms, and fruit of certain plants and protects and fosters certain scale insects that are very injurious to sugar-cane. Moreover, it has in a few instances actually shown itself to be dangerous to human life by nearly suffocating young infants.

The Argentine ant was probably first introduced into the United States through the port of New Orleans, and is now found in Louisiana, Mississippi, parts of California, and probably Texas. It is an exceedingly tenacious ant, holding on where once established, increasing with great rapidity, and driving out all the native ants.

*The termites, or white ants.*

The termites are not true ants. In fact, they stand at the opposite end of the insect-world, widely separated from the ants just discussed. They resemble the true ants, however, in many important respects. For example, they live in great colonies, and many tropical species build large mound-like nests. Moreover, in each colony there are several kinds of individuals, for example, the queen, the males, the workers which are blind or have imperfect vision, and, finally, the soldiers. The food of termites usually consists of dead or decaying wood, and the species in the United States live mostly underground or in old logs, in the timbers of buildings, or in the walls and floors of houses. Occasionally they injure young pecan and orange trees by mining into the stems and sometimes attack sugarcane. The greatest injury performed by termites, however, is by burrowing into the sills and foundation-timbers of buildings, thus undermining the whole structure. They also injure books and documents stored in damp basements and sometimes become serious pests to greenhouses.

*The control of ants in gardens, lawns and fields.*

The only method of getting rid of ants permanently is by locating the nests and treating them in such a way that the queen will finally be destroyed. The substance most used for treating the nests is carbon bisulfide. One or more holes should be made in the nest with an iron bar and an ounce or two of the liquid poured into each hole. The openings to the holes should be quickly and tightly closed with a clod of dirt. A heavy wet blanket thrown over the nest will aid in retaining the gas and tend to make the fumigation more effective. The liquid evaporates and the gas penetrates the whole nest, killing queen and workers, thus exterminating the colony.

Within the past few years, several workers have used potassium cyanide with good success in destroying ants in the field. J. D. Mitchell conducted experiments against the leaf-cutting ant in Texas. He dissolved the cyanide at the rate of one ounce in one quart of water and poured a quart into each of the openings of the nests. In every case the colony was destroyed by one or two applications. This method may be followed to advantage in destroying ants in gardens and on lawns, but the solution may be made weaker—one ounce of the cyanide to two to four quarts of water. Best results will be secured by using 98 per cent pure potassium cyanide. It must be remembered that this is a deadly poison and great care should be exercised in handling and storing it.

G. W. HERRICK.

**AÔTUS** (without ear; no calyx appendages). *Leguminosæ*. Greenhouse plant, blooming April to June in N.

Shrubs, with simple scattered or 3-whorled revolute-margined lvs., and yellow or reddish fls. in axillary clusters or short terminal racemes; calyx 2-lipped; petals long-clawed, the standard nearly orbicular and longer than lower petals, the wings oblong and keel incurved; stamens free; pod ovate, flat or turgid, 2-valved.—Ten or 11 species in Austral.

**gracillima**, Meisn. Tall shrub, with long slender branches, hoary or slightly tomentose; fls. yellow with crimson or dark-colored keel, in long leafy dense racemes, the petals twice as long as calyx. W. Austral. R.B. 26:193.

L. H. B.

**APËRA ARUNDINÆA**: *Stipa arundinacea*.

**APHANANTHE** (Greek, *aphanes*, inconspicuous, and *anthe*, flower). *Ulmææ*. Ornamental deciduous tree cultivated for its foliage and sometimes planted as a shade tree.

Trees or shrubs: lvs. alternate, petiolate, serrate; stipules free; fls. monœcious, inconspicuous; staminate

in axillary corymbs; sepals and stamens 5; pistillate solitary, axillary; ovary 1-celled with 1 ovule, styles 2: fr. a drupe.—Three to 4 species in E. Asia and Austral. The only species in cult. is a deciduous tree of the appearance of a hackberry, with slender branches forming a dense head; fls. and fr. inconspicuous. Not hardy north of Ga. Prop. by seeds sown after maturity and by cuttings of mature wood in fall; it also may be grafted on *Celtis*.

*áspera*, Planchon (*Homoicéltis áspera*, Blume. *Homoicéltis japonica*, Hort.). Tree, to 60 ft.: lvs. ovate to ovate-oblong, broadly cuneate at the base, long-acuminate, 2–3½ in. long, serrate with straight veins ending in the teeth, with appressed hairs on both sides, rough to the touch, on short stalks ½ in. long; fls. greenish, with the lvs.: drupe globular, black, ½ in. diam., short-stalked. Early spring: fr. in autumn. Japan. S.I.F. 1:37.—This tree has been confused with *Celtis sinensis*, but is easily distinguished by the straight veins ending in the teeth, while in *Celtis* they are curved and form loops along the margin.

ALFRED REHDER.

**APHELÁNDRA** (Greek-made name). *Acanthaceæ*. Tropical American evergreen shrubs or tall herbs, grown in hothouses for the fine foliage and very showy 4-sided terminal spikes of red or yellow gaudy-bracted flowers.

Leaves mostly opposite, simple, entire or toothed, usually many and large; fls. labiate, the upper lip mostly 3-lobed and the middle lobe erect or arching, the lower lip more or less 2-lobed or notched; stamens 4, rising from the base of the corolla, the anthers connivent and 1-celled; style 2-lobed: fr. a 4-angled caps.—About 60 species.

Aphelandras are of easy culture, if given plenty of diffused light in the growing season, and plants are not allowed to become tall and leggy. It is well to grow new plants frequently. Propagation is by seeds when obtainable, or by cuttings of partially ripened wood at any season or the young growths taken off with a heel. They bloom in autumn, but can readily be brought into flower at other seasons. When done blooming, the plants should be rested in an intermediate temperature, kept rather dry, but not allowed to wilt or shrivel. They require treatment of *justicias*, and thrive along with allamandas and poinsettias.

A. Fls. in yellow series.

*squarrōsa*, Nees (*A. Leopoldii*, Hort. *A. chrýsops*, Bull). Lvs. large, ovate to ovate-elliptic, acuminate, dark green above (pale below), with white rib and main veins: infl. a simple, erect, or compound spike, up to 1 ft. long; fls. pale yellow and exserted one-third their length beyond the yellow crenate-dentate bracts. Brazil. *A. squarrosa* itself is not in cult., the showy plant in the trade (and described herewith) being Var. *Leopoldii*, Van Houtte. Fig. 230. F.S. 9:889. G.C.

III, 1, p. 737. Var. *Lobisæ*, Van Houtte. Dwarfier and smaller in all its parts than var. *Leopoldii*: St. slender, dark reddish green, terete, covered in parts with soft pilose hairs, upper part of the st. below the infl. quite glabrous: lvs. 3–5 in. long, elliptic, rich dark green with brighter colored silvery markings along the midrib and principal veins: infl. 3–6 in. long, unbranched; bracts ovate, ¾ in. long, rich canary-yellow, with green markings in the middle; fls. exserted beyond the bracts over half their length, rich canary-yellow, ½ in. diam., lower 3 petals forming a lip and reflexed, upper 2 hooded, reflexing with age; tube broad, broadening out upwards with a narrow base, 1¼ in. long. Brazil. G.W. 3:157.

*Chamissoniāna*, Nees (*A. punctata*, Bull). An erect herb or sub-shrub: sts. slender, erect, terete, green, lower part more or less woody: lvs. petiolate, elliptic or elliptic-lanceolate, tapering at apex and base, and up to 6 in. long, upper part light green, marked along the principal veins and midrib with dull silvery white or yellowish white, the silvery markings sometimes spreading over nearly the entire l.; petiole short or up to an inch or more long, lower side dull light green: infl. an erect unbranched spike, as much as a foot long when strong and 2–3 in. wide; bracts ovate-lanceolate, bright yellow, tipped with green, coarsely serrate, slightly reflexed; calyx ½ in. long; sepals lanceolate; corolla bright yellow, an inch diam.; tube 1½ in. long, curved outward and tapering upward; lobes ovate, nearly equal; anthers yellow. S. Brazil. B.M. 6627. I.H. 29:457.

*Blanchetiāna*, Hook. f. (*A. amēna*, Bull). St. terete, green, tinted with dull purple, with deeper shading around the base of petiole and at the nodes, thick and stout: lvs. ovate-acuminate, with many pairs of conspicuous nerves, green, the midrib, and often the main veins, white; petiole, 1–2 in. long, terete, glabrous: fls. dark yellow, exceeding the long, entire, cusp-pointed red scales: spike sessile. Brazil. B.M. 7179.—Known in the trade as *A. amēna*, having been described under that name before it had flowered in cult.

AA. Fls. in red-orange series,—i.e., scarlet, or verging to orange.

*aurantiaca*, Lindl. Lvs. ovate-elliptic, deep green above, light green below, strongly veined, but not particularly wavy edged: fls. orange, with a tinge of scarlet, the spreading limb overhanging the greenish sharp-toothed scales.—A dwarf-growing species of easy cult. and readily raised from seed. Mex. B.M. 4224. B.R. 31:12. Var. *Rœzlii*, Nichols. (*A. Rœzlei*, Carr.). Fls. with more scarlet: lvs. twisted, with silvery hue between the veins. Mex. Gn. W. 20:576.—Showy and good. Not so tall as *A. aurantiaca*.

*Macleayi*, Bedd. Lvs. ovate-elliptic, 3 in. or less long, acute, entire, green both sides with white band along midrib above: spike cone-like, orange-scarlet, nearly 2 in. long. Country unknown.—Said to have been cult. as *A. punctata* and *A. squarrosa*.

**tetragōna**, Nees (*A. cristata*, Lindl. *Justicia cristata*, Jacq. *J. tetragōna*, Vahl). An erect or spreading, shrub: sts. terete, woody below, green, tinted with red when young; lvs. opposite and decussate, petiolate, green, glabrous or nearly so, elliptic or elliptic-ovate, acuminate or acute, 6–12 in. long, and 2–7 in. diam., entire or crenate, slightly undulate; petiole as much as 6 in. long, slender, hairy; infl. an erect-terminal cluster of spikes, the central one hairy, 6–8 in. long, with shorter ones branching from its base, often, when well grown, bearing from 10–12 lateral spikes of various lengths; fls. bright scarlet, crowded on the spike, and the bulk of them opening together; bracts erect, closely adpressed to the rachis, green, ovate, acute,  $\frac{1}{2}$  in. long, ciliate; bracteoles lanceolate, hairy; corolla scarlet,  $1\frac{1}{4}$  in. diam., tube 2 in. long, narrow at the base, broadening upwards, lip reflexed,  $1\frac{1}{4}$  in. long; upper pair of petals hooded, lateral ones reduced to short obtuse lobes. Trop. S. Amer. B.M. 8272. Gt. 40: 1354.—The finest species in cult.; a magnificent stove plant.

**nitens**, Hook. f. An erect herb or sub-shrub: st. terete, green, stout, usually dwarf and compact; lvs. shortly petiolate, ovate-acute, entire, thick, rich dark olive-green above, bright vinous purple below, highly glabrous on both sides, margins recurved; petiole very short or none, winged; infl. an erect terminal spike, 6 in. or more long; bracts green and erect,  $1-1\frac{1}{2}$  in. long, serrate; sepals  $\frac{1}{2}$  in. long, linear-lanceolate; corolla bright vermilion-scarlet,  $1-1\frac{1}{2}$  in. diam.; lip ovate, larger than the rest of the petals and slightly reflexed; upper pair of petals hooded; tube  $1-1\frac{1}{4}$  in. long, yellow. Colombia. B.M. 5741. Gn. 48:122.—A fine dwarf-growing stove plant readily prop. by cuttings and often setting seed if kept in a cooler and drier house when in flower.

**fascinator**, Lind. & André. Habit stiff and erect, with fls. opening in succession over a period of some 4–6 weeks: st. terete, green, glabrous; lvs. elliptic, lanceolate or ovate-lanceolate, acuminate, entire, shortly petiolate, 6–9 in. long, upper side dark green with narrow band of silvery white along midrib and principal veins, lower side dull wine-red with veins of a darker shade; infl. an erect unbranched terminal spike up to 6 in. long; bracts ovate or elliptic, basal ones an inch long, tapering upwards to  $\frac{1}{2}$  in. long, covered with short pilose hairs; sepals  $\frac{1}{2}$  in. long, lanceolate, glandular, green; corolla bright vermilion-scarlet,  $1\frac{1}{2}$  in. diam. with large and prominent front lobe; tube slender.  $1\frac{1}{2}$  in. long. B.M. 8398. I.H. 21:164.—A beautiful and striking species, well worth growing for its handsome foliage apart from its beautiful fls. It should be kept rather on the dry side as soon as the fls. appear, otherwise the plant is likely to lose all its roots.

*A. atrovirens*, N. E. Br. Dwarf: lvs. very dark green above and purplish beneath; fls. yellow, 1 in. long. Brazil. I.H. 31:527.—*A. liboniana*, Lind. Dwarf: lvs. ovate and long-acuminate, with a white rib, green below; fls. deep yellow, small, scarcely exerted beyond the red bracts. Brazil. B.M. 5463.—*A. macedoniensis*, Lind. & Rod. Said to be a form of *A. atrovirens*. Lvs. with white rib and main veins. Brazil. I.H. 33:583.—*A. margaritæ*, E. Morr. Lvs. elliptic-acuminate, barred with white, purple below; fls. yellow, the bracts strong-toothed. Brazil. G.C. III. 2:585.—*A. orientalis*, offered in Amer. is possibly a form of some well-known species.—*A. pumila*, Hook. f. Less than 1 ft.: lvs. large, acute; fls. orange, bracts purplish. Brazil. B.M. 6467.—*A. variegata*, Morel. A near ally of *A. Blanchetiana* with bright scarlet bracts, and bright yellow fls. Probably not now in cult. B.M. 4899. F.S. 10:981.

L. H. B.  
C. P. RAFFILL.

**APHELÉXIS**: *Helichrysum*.

**APHÝLLON** (Greek, *leafless*). *Orobanchææ*. Two species of small N. American parasitic herbs, now often united with *Orobanchæ*, and by others kept distinct under *Rafinesque's* name, *Thalesia*. These plants are not cult., but are always interesting to the collector and surprising to one who runs across them in woods or fields. *A. uniflorum*, Gray, Fig. 231, produces very

few leafless 1-fl. pale scapes, 3–8 in. high, and 5-lobed, curved, white or violet fls., and known as cancer-root. *A. fasciculatum*, Torr. & Gray, has the scaly st. rising higher out of the ground and bearing several crowded peduncles: fls. purplish yellow.—These plants occur sparingly nearly or quite across the continent.

**APICRA** (*not bitter*, from the Greek). *Liliacæ*, tribe *Aloineæ*. Aloe-like plants, grown with other succulents.

Shortly caulescent small succulents: lvs. spirally arranged or crowded along the st.: fls. greenish, often striped with white, straight, tubular or prismatic, with short, flat or spreading white limb surpassing the stamens. Cape region.—Agave house or cactus house; suitable for rockeries during the summer. Prop. like Aloe. Monogr. by Baker. G.C. II, 11:717 (1879). Journ. Linn. Soc. Bot. 18:216. Berger in *Das Pflanzenreich* 1908, hft. 33.

231. *Aphyllon uniflorum*. ( $\times \frac{1}{2}$ )

INDEX.

| deltoidea, 7.  | pentagona, 3, 5. |                 |

*A. Lvs. warty on the back: fls. smooth.*

1. **áspera**, Haw. (*Alde áspera*, Haw. *Haworthia áspera*, Haw.). St. mostly simple, erect, 4–6 in. high,  $1\frac{1}{2}$  in. diam., including lvs.: lvs. half-globose, acuminate, slightly keeled,  $\frac{5}{8}$  in. long, green, smooth on the rather convex upper surface, green-warty on the back, the margin granular; infl. scarcely 1 ft. high, unbranched; fls. somewhat rosy,  $\frac{3}{8}$  in. long, twice as long as the pedicels. Cape. Salm. Aloe §2. f. 2.—A large form with white-warty lvs. twice as long, is var. **mājor**, Haw.

2. **bicarināta**, Haw. (*Alde bicarinata*, Roem.). St. erect, 6–12 in. high: lvs. faicately short-ovate, acute, acutely keeled,  $\frac{5}{8} \times \frac{3}{4}$  in., green, smooth on the somewhat concave upper surface, irregularly white-warty on the back, the margin and keel granular roughened. Cape. Berger 40.

3. **bullulāta**, Willd. (*A. pentagōna bullulata*, Baker. *Alde bullulata*, Jacq.). St. erect: lvs. lanceolate, acute, obliquely keeled,  $\frac{5}{8} \times 1\frac{1}{4}$  in., pale, the back unequally

232. *Apicra pentagona*.

white-warty, the margin and keel finely denticulate: fls. somewhat yellow. Cape.

AA. Lvs. not warty.

B. Fls. warty: lvs. smooth.

4. *spirâlis*, Baker (*A. imbricatâ*, Willd. *Alde spirâlis*, Linn. *A. imbricatâ*, Haw. *A. cylindrica*, Lam. *Hawôrthia imbricatâ*, Haw.). Sts. somewhat clustered,

233. *Apios tuberosa*. ( $\times \frac{1}{4}$ )

erect, 6–12 in. high; about  $2\frac{1}{4}$  in. diam., including lvs.: lvs. broadly triangular-acuminate, biconvex,  $\frac{1}{2} \times 1\frac{1}{4}$ – $1\frac{1}{2}$  in., glaucescent, the margin slightly granular: infl. about 1 ft. high, unbranched; fls. greenish,  $\frac{1}{2}$  in. long, more than twice as long as the pedicels. Cape. DC., Pl. Gr. 56. Jacq., Fragm. 110. B.M. 1455. Salm, Aloe §1. f. 1. Dillenius, Eltham. 13. Commelin, Præl. 32.

BB. Fls. smooth: lvs. sometimes granular in the first.

5. *pentagôna*, Willd. (*Alde pentagôna*, Haw. *Hawôrthia pentagôna*, Haw.). Fig. 232. St. mostly solitary, erect, 6–12 in. high; about 4 in. diam., including lvs.: lvs. distinctly 5-ranked, broadly triangular-lanceolate, acute, biconvex, somewhat low-keeled,  $\frac{3}{4} \times 1\frac{1}{2}$ –2 in., green, slightly (sometimes granularly) white-dotted, the margin slightly granular: infl.  $1\frac{1}{2}$  ft. high, sometimes forked; fls. greenish,  $\frac{3}{8}$  in. long, twice as long as the pedicels. Cape. Jacq., Fragm. 111. B.M. 1338. Salm, Aloe §1. f. 4. Berger 40.—Varies into forms with lvs. less obviously 5-ranked: large, in somewhat evident oblique ranks, var. *Willdenôwii*, Baker (*A.*

*spirâlis*. Willd. *Alde spirâlis*, Haw. *A. pentagôna spirâlis*, Salm-Dyck), Salm, Aloe §1. f. 5; smaller, scarcely in distinct ranks, var. *spirêlla*, Baker (*Alde spirêlla*, Salm-Dyck. *Hawôrthia spirêlla*, Haw.), Salm, Aloe §1. f. 3.

6. *congêsta*, Baker (*Alde congêsta*, Salm-Dyck.). St. solitary, erect, about 1 ft. high and 4 in. diam., including lvs.: lvs. broadly ovate, acuminate, rather flat above, more or less keeled,  $1-1\frac{1}{4} \times 1\frac{1}{2}$  in., green, glossy, the margin granular: infl.  $1\frac{1}{4}$  ft. high, simple; fls. greenish, nearly  $\frac{5}{8}$  in. long, with rather large spreading segm.-tips, thrice as long as the pedicels. Cape. Salm, Aloe §2. f.

7. *delloîdea*, Baker (*Alde delloîdea*, Hook.). Sts. somewhat clustered, 6 in. or more high, about  $2\frac{1}{4}$  in. diam., including lvs.: lvs. distinctly 5-ranked, ovate, sub-acute, somewhat concave and low-keeled,  $1 \times 1\frac{1}{4}$ – $1\frac{1}{2}$  in., green, glossy, the margin and keel serrulate: infl. 1 ft. high, simple; fls. nearly sessile, yellow-green, about  $\frac{3}{8}$  in. long, the rather large spreading white segm.-tips at first rosy. Cape. B.M. 6071.—Varies in a form with more turgid lvs. less obviously 5-ranked, var. *turgida*, Berger (*A. turgida*, Baker), and a smaller form with evidently 5-ranked sometimes bluish lvs., var. *intermêdia*, Berger.

8. *foliolôsa*, Willd. (*Alde foliolôsa*, Haw. *Hawôrthia foliolôsa*, Haw.). Sts. somewhat clustered, erect, at length a foot or more high;  $1\frac{1}{8}$  in. diam., including lvs.: lvs. broadly ovate-acuminate, flat above, acutely keeled,  $\frac{3}{8}$ – $\frac{5}{8}$  in. long and wide, green, glossy, the margin granular: infl. over 1 ft. high, simple; fls. greenish, about  $\frac{3}{8}$  in. long, twice as long as the pedicels. Cape. B.M. 1352. Salm, Aloe §2. f. 4. Berger 40.

WILLIAM TRELEASE.

ÂPIOS (pear, from the Greek, alluding to the shape of the tubers). *Legumindœ*. Hardy twining herbs, with tuber-bearing roots, infrequently planted.

Leaves pinnate, of 3–9 mostly ovate-lanceolate scarcely stipellate lfts.: fls. in dense, short racemes, papilionaceous, the standard broad and reflexed, keel incurved and coiled; stamens 9 and 1: pod linear and flat, several-seeded.—Two species in E. N. Amer., and 3 others in Asia.

*tuberôsa*, Mœnch. GROUNDNUT. WILD BEAN. Fig. 233. Four to 8 ft., climbing over bushes: root bearing strings of edible tubers, 1–2 in. long: lfts. 5–7, ovate-lanceolate: fls. fragrant, chocolate-brown, the standard very broad and turned back, the keel long, incurved and scythe-shaped. July, Aug.—Common in low grounds and swamps. The fr. often fails to mature. Prop. by the tubers, 2–4 of which should be planted together at a depth of 3–4 in.; also, by seeds. Grows well in the wild border, in any loose, rich soil. Under these conditions, the plant covers a trellis or other support in a comparatively short time. Dry tubers offered by seedsmen are likely to start slowly. The brown of the fls. is a very unusual color in hardy herbs. Likely to become a weed in rockeries and wild gardens.

234. Fruit of *Aplectrum hyemale*. Nearly natural size.

*A. Fortunei*, Maxim., is occasionally cult. in Japan for its small, ovate, edible tubers. A.G. 13:77.—*A. Piceana*, Rob., native to Kentucky, may be expected to appear in the trade: root a single large tuber, becoming 6-7 in. diam.; fls. pale rose-color; a vigorous climber, first described in 1898 (Bot. Gaz. 25:451, with illus.).

**APIUM:** *Celery*.

L. H. B.

**APLÉCTRUM** (Greek, *with no spur*). *Orchidaceæ*. A small orchid, with smallish dull-colored fls. in a raceme, on a leafless scape, which springs from a large corm-like tuber. Single species (or possibly two), in woods in the northern states.

Flower spurless and sacless; petals and sepals similar, narrow; lip 3-lobed and crested, deflexed; fertile anther 1, the pollen-masses 4, smooth and waxy; column free, compressed, the anther borne below the top.

**hyemåle**, Nutt. (*A. spicatum*, B. S. P.). PUTTY ROOT. ADAM-AND-EVE. Fig. 234. Sends up a pointed green lf. 2-6 in. long, which lasts through the winter, and in spring a stalk about a foot high, bearing a raceme of rather large greenish brown fls., which are succeeded by hanging, oblong-pointed pods (Fig. 234).—Hardy. May be grown in rich, loamy borders. Interesting, but not showy.

L. H. B.

**APLOPÁPPUS** (Greek, *simple pappus*). Syn., *Haplopappus*. *Compósitæ*. Herbaceous perennials, sometimes offered for the hardy border.

Leaves mostly stiffish or rigid, alternate: heads radiate, many-fld., the rays pistillate; involucre hemispherical, with several series of closely imbricated bracts: pappus simple, of many unequal bristles, the achene short and narrow.—A genus of about 115 species

235. *Aponogeton distachyus*. ( $\times \frac{1}{2}$ )

of herbaceous perennials, rarely shrubs, mostly from Calif. and Chile. Fls. yellow, in summer and autumn. Separated only by technical characters from *Bigelovia*, into which it insensibly grades. (*Bigelovia* has discoid few-fld. heads and pappus in single row.) The only 3 species known to have been in the American trade are

**lanuginosus**, Gray. Hardy alpine herb, woolly, 4 in. high, from creeping rootstocks; lvs. soft, narrowly spatulate, or upper linear, 1-2 in. long; rays 15-20. Mts. of Wash. and Mont.—Intro. 1889, by F. H. Horsford.

**Párryi**, Gray. Alpine herb, 6-18 in. high, green and almost glabrous; lvs. oblong-obovate, 2-4 in. long; fl.-heads about  $\frac{1}{2}$  in. high, pale yellow, the involucrel bracts oblong and obtuse; rays 12-20, small and narrow.—Suitable for rockwork.

**cræceus**, Gray. St. about 1½ ft., erect and stout, and with radical lvs. a foot or less long; cauline lvs. ovate-oblong to lanceolate, partly clasping; fls. showy, saffron-yellow, the rays about an inch long, the inner involucrel bracts ragged. Rocky Mts. June-Oct.

*A. ericoides*, Hook. & Arn. Shrub, 2-5 ft. high; lvs. very numerous, filiform, those of the dense fascicles, 2 or 3 lines long; fls. very numerous. G.C.III. 20:301.

N. TAYLOR.†

**APÓCYNUM** (Greek for *dog-bane*). *Apocynaceæ*. DOG-BANE. INDIAN HEMP. Native herbs, sometimes planted in borders.

Flowers small, the calyx with acute teeth; corolla

bell-shaped, with 5 appendages inside; stamens 5, inserted deep in the corolla, the filaments very short; style 0: seeds silky.—Tough perennial herbs, with milky juice, chiefly of north temperate zone, with oblong or ovate, opposite lvs., milkweed-like fls. in small cymes, and slender follicles or pods. About 25 species, 10 native to N. Amer.

**androsæmifolium**, Linn. SPREADING DOG-BANE. Three ft. or less high, usually glabrous, the branches spreading; lobes of corolla revolute and tube of corolla longer than the calyx; lvs. oval or ovate, mucronate, short-petioled; cymes loose, axillary and terminal; fls. bell-like, white or pink. N. N. Amer.; common. B.M. 280.—Sold by dealers in native plants. Useful for the hardy border as it will stand dry open places. Root used in medicine; sometimes gathered by drug-collectors for *A. cannabinum*, but as its action is different, it should not be substituted.

**cannabinum**, Linn. Branches erect or nearly so: lobes of corolla nearly erect, the tube not longer than calyx; lvs. ovate to lance-oblong, short-petioled; cymes dense; fls. greenish white. Northern states; common.—Not known to be in the trade, but likely to be confounded with the above. Root emetic, cathartic, diaphoretic, expectorant, and diuretic. The tough fibrous bark of the stalks formerly used by the Indians for making twine.

L. H. B.

**APODOLÍRION** (Greek combination, *footless lily*, the peduncles not being evident). *Amaryllidaceæ*. Greenhouse bulbs of S. Afr., of which one or two of the half-dozen species are rarely cult. Bulb tunicated: fl. 1, borne or hidden in the bulb-neck in the manner of

crocus, white or reddish: lvs. usually not appearing with the fls., narrow. **A. Êttæ**, Baker, and **A. lanceolatum**, Baker, are probably best known as cult. plants. The former has a white, tinged red fl. 3 in. long and crocus-like lvs.; the latter (*Gethyllis lanceolata*, Linn. f.) has a much shorter fl., white or whitish, and a solitary lanceolate lf. appearing with the fls. The apodolirions are prop. by offsets or seeds.

**APONOGÈTON** (Greek name, referring to its habitat in the water). *Aponogetonaceæ*. Aquatics, mostly with flat floating lvs. and emerging spikes of fls. Includes *Ouvirandra*.

Submerged herbs, with tuberous rhizomes and fibrous roots; lvs. long-stalked, oblong or linear, sometimes lacking the parenchyma and having a lattice-like character: fl.-characters those of the family (p. 13).—About two dozen species of warm countries, Asian, African and Australian. Krause & Engler, *Das Pflanzenreich*, hft. 24 (1906). There are two main species in cult., the aponogeton proper with solid lvs., and the ouvirandra with open-work lvs. The former is grown mostly out-of-doors; the latter in warm green-houses.

**distachyus**, Linn. f. CAPE POND-WEED. WATER HAWTHORN (from the fragrance). Fig 235. Fls. in twin spikes on the emersed ends of long scapes, wholly naked, but subtended by a double row of petal-like bracts, very fragrant, with purple anthers:

lf.-blade floating, oblong-lanceolate, round-based, parallel-veined, 3-6 in. long. Cape of Good Hope. B.M. 1293. F.R. 1:463. P.G. 4:106. G.W. 5:195. Gng. 2:25. —A charming and interesting plant. In a protected pool, especially if it can be covered in winter, the plant is hardy in the N., blooming nearly all summer. Removed to tubs in the fall, it blooms nearly all winter; or it can be grown permanently in tubs or deep pans in the house. Requires about 2 ft. of water, or out-of-doors it may have twice that depth. Prop. chiefly by seeds, but fls. should be pollinated and kept above water at least 24 hours afterward, and seeds not be allowed to become dry. Var. *Lagrängei*, Hort. (A.

236. *Aponogeton fenestralis*, the lace-leaf plant. Known to gardeners mostly as *Ouvirandra*.

*Lagrängei*, Hort.), is a rare and beautiful variety, with violet bracts and lvs. violet beneath. It props. slowly. R.H. 1895:380.

*fenestralis*, Hook. f. (*Ouvirandra fenestralis*, Poir.). LACE-LEAF. LATTICE-LEAF. Fig. 236. Lvs. oblong, 6-18 in. long and 2-4 in. broad, reduced to skeletons, floating just under the surface of the water: fls. small, consisting of 6 stamens, 3 pistils and 2 white petal-like bodies, numerous, in 2 spikes each about 2 in. long, which are united at the base, and borne on the top of a scape a foot or so long. Madagascar. A.F. 7:67. A.G. 15:169. B.M. 4894. Gt. 1863:387. G.M. 38:830. Gn. 30, pp. 344, 345. Mn. 6, p. 231. F.S. 11:1107. I.H. 8:300. G.W. 10:595 (var. *major*).—The lvs. are merely a tracery of nerves and cross-veins, but despite their lace-like delicacy they can be handled with considerable roughness. The venation of the lace-leaf plant is like that of the common aponogeton, and now and then a lf. occurs in which the spaces between the veins are partly or wholly filled with green matter. There is another species with skeletonized lvs. (*A. Bernierianus*), but the open spaces are smaller and the plant is less desirable for cult.

The lace-leaf plant can be grown in a tub in a warm greenhouse. For some unknown reason the plant seems rarely to succeed in a jar or glass aquarium. Some cultivators think that the water must be changed every day, but this is not necessary. If confervæ appear, introduce a few tadpoles and snails; these will devour the green scum, and help to keep the plant in good health by furnishing oxygen. See *Aquarium*. The plant should be potted, and plunged not more than 18 in. below the surface of the water. For potting soil use a rich compost, such as is recommended for water-lilies. The water should be kept clean and sweet, and a

237. *Aporocactus flagelliformis*. ( $\times \frac{1}{2}$ )

temperature of 65-70° provided. Avoid direct sunlight. In Madagascar the streams often dry up, and the tubers carry the plant over the dry season. In imitation of nature some cultivators take the tubers out of the soil, and leave them on a shelf in a hot-house during the month of Feb. It is doubtful whether

this is necessary. Potting should be done while the plant is in active growth, not dormant. Prop. by division. The lace-leaf is cult. in all the finest collections of aquatics, and is prized as a curiosity.

*A. angustifolius*, Ait. (A. capensis, Perry). Like *A. distachyus*, but much smaller: fls. small, white. S. Afr.—*A. Bernierianus*, Hook. f., differs from *A. fenestralis* in having smaller open spaces in the lvs., and pinkish 4-parted spikes.—*A. Dinteri*, Engl. & Kr. Tuber globose: floating lvs. oblong, rounded or somewhat emarginate at base, long-nerved, not lace-like: inflorescence 2-spiked, yellowish. German S. W. Afr. G.W. 14:659.—*A. Henckelianus*, Hort. Allied to *A. fenestralis*, but rhizome larger and not creeping: lvs. pale green, less lasting. Madagascar. G.C. III, 40:270.—*A. monostachyus*, Linn. f. (A. natans, Engl. & Kr.) Lf. linear-oblong infl. in 1 spike, pink. India, Austral. G.W. 9:62.

L. H. B.

WM. TRICKER.

### APOROCÁCTUS (Greek, *impenetrable* and *cactus*).

*Cactaceæ*. A very slender vine-like creeping, clambering, or hanging cactus, sending out aerial roots: fls. rather small, slender, somewhat irregular, bright red: fr. small, globose, reddish, setose.—Three species recognized, the one below and *A. flagriformis*, Lem., and *A. leptophis*, Britt. & Rose. Only one appears to be in cult. These plants are commonly referred to *Cereus*.

*flagelliformis*, Lem. (*Cereus flagelliformis*, Mill.). RAT-TAIL CACTUS. Fig. 237. Sts. about  $\frac{1}{2}$  in. diam., branching: ribs 10-12: fls. 2-3 in. long. Trop. Amer.—This is commonly hybridized with other species. It is a well-known window-plant. It is easily grown and is a great favorite with people who know little about cacti. It is often grafted on other cacti and worked into various fantastic designs. It is rather a free bloomer, and with proper care a most charming plant can be obtained.

J. N. ROSE.

**APOSÈRIS.** An alpine composite, now included in the genus *Hysomeris*, which see.

**APPLE.** *Rosaceæ*. The fruit and tree of *Pyrus Malus*, one of the rosaceous group. The name is also applied, with qualifications, to many other edible fruits, as may-apple, pond-apple, rose-apple.

The apple is native to southwestern Asia and adjacent Europe. It has been cultivated from time immemorial. Charred remains of the fruit are found in the prehistoric lake dwellings of Switzerland (Fig. 238). Now widely cultivated and immensely variable, the apple is grown in every temperate climate, and is probably the most important commercial pomological fruit.

The apple has come apparently from two original stems. All the common apples are modifications of *Pyrus Malus* (see *Pyrus*), a low round-headed tree, with thick and fuzzy irregularly dentate, short-stemmed leaves and fairly compact clusters of woolly-stemmed flowers. The crab-apples are derived chiefly from *Pyrus baccata*, commonly known as the Siberian crab. This species is probably of more northern or eastern origin than the other. It is of smoother and more wiry growth, with narrower and thinner essentially glabrous long-stemmed leaves, and more open clusters of glabrous-stemmed flowers. The apple is small and hard, and the calyx-lobes fall at maturity, leaving the eye or basin of the fruit smooth and plain. Hybrids between these species apparently have given the race of large-fruited crab-apples, of which the Transcendent and Hyslop are examples. The race known to pomologists as *Pyrus prunifolia* is perhaps a hybrid group. Certain apples are native to North America. Two species, *Pyrus ioensis* and *P. coronaria*, are of interest to the pomologist. The former is the prairie-states crab, and is the more promising. In characters of growth, leaves

238. Apple remains from the Swiss lake dwellings.

VII. The flowers of the apple tree.

and flowers, it bears a striking resemblance to forms of *Pyrus Malus*. The fruit is spherical or spherical-oblong, short-stemmed, very hard, and remains green-colored. The fruit of the eastern-states crab, *Pyrus coronaria*, is distinctly flattened endwise, and is long-stemmed. The leaves are deep-cut and often three-lobed. There are no improved varieties of this eastern species, and no authentic hybrids between it and the common apples. The fruit is sometimes used by settlers, but it has little comestible value. *Pyrus ioensis* has produced a number of promising hybrids with the common apple, and this mongrel race is known as *Pyrus Souldardii*. The Souldard crab is the best known of these. Its value lies only in its extreme hardiness. The pomological value of the native crabs is prospective. For a completer account of the native apples, see Bailey, "Evolution of our Native Fruits."

One of the most perfect apple regions of this country—considering productiveness, quality, long-keeping attributes, longevity of tree—is that which begins with Nova Scotia and extends to the west and southwest to Lake Michigan. Other important regions are the Piedmont country of Virginia and the highlands of of adjacent states; the Plains regions; the Ozark and

especially important, in our hot and sunny country, that the roots extend deep enough to escape the disastrous effects of drought. The ideal treatment of orchard land is to fit the ground deep before the trees are replanted, to plow deep for a year or two or three in order to force the roots down and thoroughly to ameliorate the soil, and to practise shallow tillage to conserve moisture. Since trees make most of their growth early in the season, the tillage should be begun as soon as the land is fit in spring; and it may be discontinued by midsummer or August. This cessation of

241. Showing the side bud that is to continue the spur the following year.

the tillage allows of the growing of some cover-crop or catch-crop late in the season, in order to provide humus and to improve the physical texture of the soil. If the land is well handled in the first few years, it will not be necessary to turn a furrow in the orchard frequently thereafter, but merely to loosen the surface in the spring with a spading-harrow, spring-tooth harrow, or other tool, to reestablish the surface mulch. The only reasons for turning a furrow will occur when the land is so hard that the surface tools cannot mellow the surface, or when it is desirable to turn under a green-manure crop. Even hard lands may be got in such condition, by means of tillage and green-manures, that they may be worked up with harrow tools when the orchard comes into bearing. Plowing the orchard, therefore, has two legitimate objects: to mellow and ameliorate the land to a considerable depth, so that the roots may forage deep; to turn under a cover-crop. The former purpose should not be necessary after the first few plowings. An incidental object of plowing is to facilitate the making of the annual surface mulch; and this mulch is to save the moisture.

On good lands in which there is a sufficient natural supply of moisture, the sod-mulch treatment may take

239. Spur and fruit-bud of apple.

240. Only one fruit may set in a cluster.

Arkansas region; the intermountain region from Montana to New Mexico; the Northwest, including both large and small areas in British Columbia, Washington and Oregon; and the Pacific region, comprising the foothills and parts of the coast in California. All parts of the United States north of Florida and the Gulf borders, and excluding the warm-temperate parts of the Southwest, are adapted to the apple in greater or lesser degree. North America is the leading apple-growing country of the world. A full crop for the United States and Canada, of all kinds and grades, is probably not much less than 100,000,000 barrels, although it is doubtful whether more than one-third of this vast quantity is marketed in a fresh state. The apple is a cosmopolitan fruit, and, since it thrives almost anywhere, it is commonly neglected.

The apple was early introduced into this country. In the first days it was prized chiefly for cider. It is an ancient and common notion that any apple is good enough for cider; and this is one reason for the neglect in which the apple plantation was commonly allowed to stand.

#### Brief or summary statement.

The best results in apple-growing are to be expected in general when the land is tilled. The reasons for tilling the orchard are those that apply to other crops,—to make plant-food available, to extend the area in which the roots can grow, to conserve moisture. It is

242. The flower-cluster and the leaf-cluster.

the place of tillage. This procedure keeps the land in sod, and the grass is mown and allowed to remain on the ground or is spread under the trees.

The apple thrives in a variety of soils. Lands that yield good crops of wheat and corn may be expected to be good apple lands, if other conditions are right. Rolling, inclined, or somewhat elevated lands are generally considered to be most desirable. Their value lies in the better drainage of water and air. The trees may be set in either fall or spring. Forty feet apart each way is the standard distance for apple trees; but some varieties, as the Wagener and the crabs, may be set closer. In the South and on the plains, trees may

be set closer, as they do not attain such great size as in the northeastern states. In general, it is best to devote the land to apples alone; but persons who are willing to

give the plantation the best of care may plant other trees between the apples as fillers. The more diverse the kinds of trees which are planted together, the more difficult it is to give the proper care to each. Some of the shorter-lived varieties of apples make excellent fillers in the apple orchard; and in special cases dwarf apples may be used.

Although it should be the general purpose to till the apple orchard throughout its life, whenever the trees seem to be growing too rapidly, the plantation may be seeded down for a time. That

is, tillage is the general practice; seeding down and sod-mulching are the special practices. For the first few years, annual crops may be grown in the apple

orchard; but every year a more open space should be left about the trees. As often as the land becomes crusted it should be tilled. On strong lands which are well handled, it is rarely necessary to apply concentrated fertilizers until the trees are old enough to bear. What fertilizers are then needed, and how much to apply, are to be determined by the behavior of the trees. If the trees are making insufficient growth, and the foliage lacks color, one or all of three things may be the

that they lack nitrogen, this material may be supplied in the form of nitrate of soda, sulfate of ammonia, or the unburned animal substances, as blood and tankage.

Two to three hundred pounds to the acre of the nitrate of soda or sulfate of ammonia are liberal applications on well-tilled lands. If the trees are making vigorous growth, the probability is that they are not in need of more nitrogen. Potash and phosphoric acid may then be applied. Three hundred pounds of muriate of potash, or other concentrated material, should be sufficient for an acre, under ordinary conditions. As a rule, all orchards in full bearing should have a liberal annual application of fertilizing materials. In the East, apple trees should be in profitable bearing at twelve years from planting, and should continue for thirty years. In recent years, lime has been applied in many cases with good results, about 1,000 pounds to the acre every four or five years.

The two staple enemies of the apple are the apple-worm (the larva of the codlin-moth), and the apple-scab. These are readily held in check by spraying,—with arsenical poisons for the worm, and with lime-sulfur or bordeaux mixture for the scab. See *Spraying*. Spraying for the worm should be performed as soon as the last petals fall; for the scab as soon as the buds are well burst. In badly infected regions and on very susceptible varieties, it may be necessary to spray first

247. Gano. ( $\times \frac{3}{8}$ )

248. Black Gilliflower. ( $\times \frac{5}{8}$ )

249. Grimes. ( $\times \frac{1}{2}$ )

243. Baldwin. ( $\times \frac{1}{2}$ )

244. Ben Davis. ( $\times \frac{3}{8}$ )

trouble: the trees may need water; they may be suffering from insects or disease; they may lack nitrogen. If it is thought

245. Blue Pearmain. ( $\times \frac{3}{8}$ )

246. Esopus (Spitzenberg). ( $\times \frac{3}{8}$ )

for the scab before the buds swell. Since there are insects (as canker-worms, case-bearers, bud-moth) that appear before the flowers open, it is advisable to add arsenical poison to the fungicide at the early spraying. The number of times to spray depends on the thoroughness of the work, the pests to be combated, and the season; but it is a good rule to expect to spray with the combined fungicide and insecticide mixture when the buds burst, and again when the petals have fallen. In the plains country, less spraying may be necessary for the fungous diseases.

The apple commonly bears on spurs. The fruit-bud is distinguished by its greater size (usually somewhat thicker than its branch), its greater width in proportion to its length, and more conspicuous pubescence. It is also distinguished by its position. A fruit-bud is shown in Fig. 239. A fruit-scar is shown near the base of the branch. If this fruit was borne in 1912, the side branch grew in 1913 from a bud which came into existence in 1912. If we go back to the spring of 1912, the matter can be made plain. A cluster of flower appeared. One flower set a fruit

(Fig. 240). This apple is at the end of the branchlet or spur. The spur cannot increase in length in the same axis. Therefore, a bud appears on the side (Fig. 241). The fruit absorbs the energies of the spur. There is little nourishment left for the bud. The bud awaits its opportunity; the following year it grows into a branchlet and makes a fruit-bud at its end (Fig. 239); and thereby there arises an alternation in fruit-bearing, although not all alternating in fruit-bearing may be attributed to this cause. The difference between fruit-buds and leaf-buds becomes apparent when the buds burst (Fig. 242).

The apple is budded or root-grafted on common apple seedlings. These seedlings are usually grown from seeds secured from cider mills. In the East, budded trees are preferred. In the upper Mississippi Valley, root-grafted trees are preferred, largely because own-rooted trees of known hardiness can be secured. In Russia, seedlings of *Pyrus baccata* are used as stocks. They prevent root-killing, and give earlier fruit-bearing. Apple trees are usually planted when two or three years old.

Apples are dwarfed by working them on various kinds of Paradise and Doucin stocks. These stocks are merely naturally dwarf forms of the common apple, and which, in some remote time, have originated probably from seeds. Dwarf apples are much grown in Europe, where small-area cultivation and wall-training are

250. Hubbardston. ( $\times \frac{3}{8}$ )

254. Rome Beauty. ( $\times \frac{3}{8}$ )

251. Yellow Newtown. ( $\times \frac{1}{2}$ )

255. Wealthy. ( $\times \frac{3}{8}$ )

253. Rhode Island Greening. ( $\times \frac{3}{8}$ )

257. York Imperial. ( $\times \frac{3}{8}$ )

common, but they are little known in America, and, because of economic conditions, are usually not profitable here. See *Dwarfing*.

#### Varieties.

The varieties of apple trees actually on sale in North America in any year are not far from 1,000 kinds. Each great geographical area has varieties that are particularly adapted to it. In the northern Mississippi Valley, there are few of

258. Tompkins King,—the flat or oblate American apple. ( $\times \frac{1}{2}$ )

the eastern-states apples that thrive. Varieties have been introduced from Russia with the expectation that they will be adapted to the region; but more is to be expected of their progeny than of themselves. Varieties of local origin, coming from various stem types, are now providing that region with satisfactory apples. In the selection of varieties, one should be guided by this adaptation to the region, and by the purpose for which the fruit is designed to be grown. Consult the recommended lists of the state horticultural societies; ask persons who have had experience in the given region; write to the experiment station; enquire at the markets. The leading commercial varieties in North America are Golden Russet (N. Y.), Red Astrachan, Baldwin (Fig. 243), Ben Davis (Fig. 244), Blue Pearmain (Fig. 245), Oldenburg (Duchess of), Esopus (Spitzenberg) (Fig. 246), Fameuse, Gano (Fig. 247), Black Gilliflower (Fig. 248), Gravenstein, Grimes (Fig. 249), Hubbardston (Fig. 250), Ralls, Jonathan, Tompkins King, McIntosh,

259. The oblate and spherical forms of apple.

260. The conical and ovoid forms of apple.

262. Monument to the Baldwin apple.

263. Tablet to the Primate apple.

Missouri (Pippin), Newtown (Albemarle) (Fig. 251), Northern Spy (Fig. 252), Peck (Pleasant), Fennock, Rhode Island Greening (Fig. 253), Rome Beauty (Fig. 254), Shockley, Twenty Ounce, Wealthy (Fig. 255), Willow (Twig), Winesap and Stayman Winesap (Fig. 256), Wolf River, Yellow Bellflower, York Imperial (Fig. 257), King (Fig. 258). Baldwin and Ben Davis, the former of secondary quality and the latter of worse, hold the supremacy in American market apples. The apples of the eastern and central country tend toward flattened or oblate shape (Figs. 258-9). The typical form of the so-called long or conical American apple may be seen in Fig. 260. Many odd and unusual varieties are grown for dessert, one of which is shown in Fig. 261.

261. Lady, a small dessert apple. ( $\times \frac{1}{2}$ )

Monuments or markers have been erected to a few of the most noted varieties of apples. Fig. 262 shows the monument erected in Wilmington, near Lowell, Mass., in 1895, to the Baldwin, with the following inscription:

THIS PILLAR ERECTED IN 1895  
BY THE

RUMFORD HISTORICAL ASSOCIATION

Incorporated April 28, 1877

Marks the estate where in 1793 Samuel Thompson, Esq., while locating the line of the Middlesex Canal, discovered the first Pecker apple tree. Later named the

BALDWIN

The first tablet in New York state in memory of any apple was erected in the town of Camillus, Onondaga County, on the original site of the Primate apple tree (Fig. 263). John T. Roberts, Syracuse, N. Y., on September 11, 1903, caused a bronze tablet to be erected there. On this tablet is the following inscription:

On this farm Calvin D. Bingham, about 1840, produced  
the marvellous

PRIMATE APPLE

Named by Charles P. Cowles

GOD'S EARTH IS FULL OF LOVE TO MAN

A second marker was erected in New York in 1912 to the Northern Spy, Early Joe and Melon apples, at Bloomfield, by the Ontario County Fruit-Growers' Society (Fig. 264), with the following tablet:

264. Northern Spy monument  
(4 ft. high.)

### THE ORIGINAL NORTHERN SPY APPLE TREE

stood about 14 rods south of this spot, in a seedling orchard planted by Heman Chapin about 1800.

THE EARLY JOE AND MELON APPLES  
ALSO ORIGINATED IN THIS ORCHARD

The McIntosh apple (McIntosh Red) is commemorated (Fig. 265) by a monument at Dundela, Dundas County, Ontario, as follows:

### THE ORIGINAL MCINTOSH RED APPLE TREE

stood about 20 rods north of this spot. It was one of a number of seedlings taken from the border of the clearings and transplanted by John McIntosh in the year 1796.

ERECTED BY POPULAR SUBSCRIPTION 1912.

The history is that John McIntosh came to Canada with the United Empire Loyalists. After spending some time along the frontier, he settled on his homestead in the county of Dundas in 1790 at a place later called McIntosh's Corners, although that place has now become extinct and Dundela has taken its place. In the year 1796 while clearing some forest land, he came upon a clump of young apple trees, about twenty in number. As apples were at that time a luxury, the apple trees were left unharmed, and a few days after were replanted in a clearing nearer his house. Most of the trees thrived for a few years but finally died. In 1830 only one tree out of the twenty remained. As this apple was unnamed, Mr. McIntosh combined

265. Monument to the McIntosh apple. (5 ft. high.)

color of the apple and christened it "McIntosh Red." From the time it was transplanted, it grew rapidly and in a few years bore an abundance of fruit the color and flavor of which attracted the attention of the earlier settlers. It was situated about fifteen feet from the house, and when in 1893 the house was burned, the tree also received its share of the fire and one side was badly burned. Nevertheless, the other side continued to bear until 1908. That summer the leaves began to wilt and the apples to fall off until it was entirely bare. Thus the old tree which had withstood the storm of 112 years was forced at last to submit to the injuries received from the fire of 1893 (Fig. 266). The wide circulation of the McIntosh apple is due to his son, the late Allen McIntosh, who, fully appreciating the fruit, wished others to enjoy it also and started propagating by grafting and budding from the original tree. This has been repeated year after year since 1836.

The origin of the Wealthy apple, the leading variety of the upper Mississippi Valley, is commemorated on the monument erected to the memory of Peter M. Gideon, Excelsior, Minnesota (Fig. 267). The tablet was unveiled and dedicated with appropriate ceremonies on the old farmstead, where he passed the last forty-six years of his life, at 2 o'clock on the afternoon of Saturday, June 15, 1912. The memorial consists of a block of granite, raised on a platform of solid concrete, surrounded by a chain supported by a number of black iron posts. On the sloping top of stone is a bronze tablet bearing this inscription:

This Tablet commemorates Peter M. Gideon who grew the original

### WEALTHY APPLE TREE

from seed on this<sup>a</sup> his homestead, in 1864.  
Erected by the Native Sons of Minnesota, June, 1912.

The triangular piece of ground on which this is placed containing approximately a half-acre, is surrounded by a chain and post fence. This ground, the gift of O. P. Briggs, is dedicated as "Gideon Memorial Park." It lies on the main traveled boulevard between Excelsior and Minnetonka Beach, a few hundred feet south of the Manitowish station on the electric line.

266. Original McIntosh apple tree.

### Special literature.

Several books devoted wholly to the apple have appeared in North America: Warder, Apples, 1867; Todd, Apple Culturist, 1871; Waugh, The American Apple Orchard, 1908; Burritt, Apple Growing, 1912; Woolverton, Canadian Apple Grower's Guide. For varieties, the two volumes, Beach, Apples of New York, published by the New York Agricultural Experiment Station, at Geneva, are invaluable. Consult, also, Vol. 25, Nebraska State Horticultural Society, 1894; The Apple, a report of the Kansas State Horticultural Society, 1898. Nearly all the fruit manuals devote space to the apple.

L. H. B.

### Apple-growing in the northeastern states.

Although the eastern region (New England, New York, Pennsylvania) early developed an apple industry, it had few commercial orchards until near the middle of the last century. About that time many named varieties of American origin were disseminated. At first the product was used largely for the making of cider. Gradually there arose a demand for fresh fruit,

267. Monument to Peter M. Gideon and the Wealthy apple.

and as transportation facilities improved and the business became more profitable, there was a rapid increase in the number and size of the orchards. The production of apples increased more rapidly than the facilities for distribution and soon the supply apparently exceeded the demand. The low prices received in the following years discouraged the growers from further planting. Many growers, being attracted by the

alluring settlement of the West and others by the opportunities in the rapidly growing manufacturing centers, forsook their orchards. Of those who remained, many cut down the trees to make room for more profitable crops. The orchards that remained were mostly neglected and many of them may still be found, although few of them are now profitable. There have been two or three attempts at reviving the industry and these mark well-defined epochs of orchard planting.

With the phenomenal amassing of population in the eastern cities and with the marked improvement in transportation facilities, there has developed within the past ten years a remarkable opportunity in the growing of apples. As a result, enormous areas are being planted and many of the old and neglected orchards are being revived. Many persons from the cities are being attracted to the cheap lands in the East and most of them are planting apple trees. It is difficult to ascertain, even in an approximate way, the number of trees being planted in any section. The thirteenth census shows that there are over 7,425,000 apple trees in the eight states under discussion that had not reached the bearing age in 1910, and there has been much greater activity in tree-planting in the three subsequent seasons than ever before. Many of the old orchards, however, are fast passing out of existence. From the census reports it may be seen that despite the number of young orchards coming into bearing in the ten-year period, there were 10,488,000 more trees of the bearing age reported in 1900 than in 1910.

The question of the probability of over-production immediately arises. Most of the growers are still optimistic, thinking that for various reasons many of the orchards will never reach the bearing age and that with the rapidly growing population, the increasing opportunities for exporting, the raising of varieties of better quality, and with better methods of grading and packing, the supply will not exceed the demand for any considerable time.

#### *Apple regions.*

It is remarkable that the apple industry has reached its highest development in certain restricted regions. When pomologists speak of the western New York fruit-belt or the Champlain Valley district, a fairly definite area is understood. Usually such districts are marked by exceptionally favorable soil or climatic conditions. The conspicuous apple regions of the Northeast, although frequently hundreds of miles apart, possess about the same set of conditions. This is especially true within the same parallels of latitude. The distinctive features of these regions are:

(1) A favorable climate, that insures protection from extreme temperature, affords sufficient rainfall in summer, and that furnishes long days and abundant sunshine throughout the growing season.

(2) A favorable soil, that insures good drainage, ease of cultivation, and a spacious feeding-ground for the roots.

(3) A suitable topography, that affords adequate atmospheric drainage and insures protection from frosts and freezes. Lands adjacent to large bodies of water, however, are not necessarily dependent upon variations in altitude to insure protection from frost.

While favorable soil, climate and topography often are determining factors and are considerations of great

importance, there is now known to be much greater latitude in this respect than was generally considered. In recent years, apples have been successfully and profitably grown under conditions that formerly were thought to be very undesirable. This is mentioned here to show that the proper selection of varieties and the adoption of special methods of treatment are also important factors, and that the "fruit-belt" is not the only controlling factor.

The accompanying table gives some information regarding the number of apple trees and the production of apples in the states under consideration. One column also shows the relation of the production of the various states to the total production of the United States:

VARIOUS APPLE STATISTICS FOR THE NORTHEASTERN STATES, ACCORDING TO THE CENSUS REPORTS FOR 1900 AND 1910.

State	Bushels 1899	Bushels 1909	Per cent of total pro- duction of U. S. 1909	Trees of bearing age		Trees not of bearing age 1910
				1900	1910	
Maine.....	1,422,000	3,636,000	2.48	4,185,000	3,477,000	1,045,000
N. Hampshire..	1,979,000	1,108,000	.08	2,034,000	1,241,000	207,000
Vermont.....	1,177,000	1,460,000	.10	1,675,000	1,184,000	220,000
Massachusetts..	3,023,000	2,550,000	1.73	1,852,000	1,367,000	356,000
Rhode Island...	339,000	213,000	.01	214,000	152,000	55,000
Connecticut....	3,709,000	1,541,000	1.04	1,167,000	799,000	212,000
New York.....	24,111,000	25,409,000	17.22	15,055,000	11,248,000	2,829,000
Pennsylvania...	4,641,000	11,048,000	7.49	11,774,000	8,000,000	2,501,000
Total.....	40,401,000	46,965,000	31.83	37,956,000	27,468,000	7,425,000

By comparing the production from the various counties, it is easy to determine the conspicuous apple sections. The following table shows the production from the twenty-four highest producing counties in the northeastern states:

TABLE SHOWING PRODUCTION OF APPLES FROM THE TWENTY-FOUR HIGHEST PRODUCING COUNTIES IN THE NORTHEASTERN STATES, CENSUS OF 1910.

County	State	Bushels
Wayne .....	New York	3,304,000
Monroe.....	New York	2,592,000
Niagara.....	New York	2,367,000
Orleans.....	New York	2,229,000
Ontario.....	New York	913,000
Columbia.....	New York	893,000
Dutchess.....	New York	795,000
Ulster.....	New York	668,000
Chautauqua.....	New York	646,000
Middlesex.....	Massachusetts	633,600
Greene.....	New York	630,000
Wyoming.....	New York	625,000
Erie.....	New York	623,000
Worcester.....	Massachusetts	595,000
Genesee.....	New York	581,000
Cattaraugus.....	New York	558,000
Albany.....	New York	528,000
Cayuga.....	New York	484,000
Oxford.....	Maine	443,000
Berks.....	Pennsylvania	426,000
Oswego.....	New York	406,000
Tioga.....	Pennsylvania	399,000
Kennebec.....	Maine	392,000
Franklin.....	Maine	389,000

It will be seen that of the twenty-four counties, seventeen are in New York state, three in Maine and two each in Massachusetts and Pennsylvania.

The territory under consideration lies mostly between the 68th and 81st degrees of longitude and the 40th and 46th degrees of latitude. It possesses, on the whole, a very irregular topography, resulting from glacial deposits. It is drained in almost all directions by rivers of various sizes. It includes many fertile valleys, elevated plateaus, and several mountainous areas. Along

the coast in many sections, and on the shores of the Great Lakes are fairly broad low-lying plateaus. These areas, with the broad river valleys and their bordering slopes, are of great importance from a fruit-growing standpoint.

In a rough way, the lands may be divided into two main groups. The first embraces the river valleys, including the valley slopes, and the lower plains adjacent to the Great Lakes, and certain areas near the coast. To this group belong the most conspicuous apple-growing areas, such as those along the valleys of the Connecticut, the Hudson, the St. Lawrence, the Mohawk, the Susquehanna and other smaller rivers, and the shores of Lake Erie, Lake Ontario, Lake Champlain and various inland lakes.

The second group of lands embraces the uplands, composed usually of more or less rolling land with innumerable hills, narrow valleys, and great plateaus. This territory embraces much rough mountainous land that is of little value except for forestry. In general, the upland territory is devoted mainly to diversified farming. As a rule, only the hardier varieties of apples are grown, but in the uplands there are innumerable areas of restricted dimensions that are well adapted to the growing of apples in conjunction with other interests.

In the East apples are extensively grown for home use and for local market. For this reason the apple industry is not so centralized as it is in some other regions, although there are many large commercial orchards. Many individual orchards are small, being on diversified farms. According to the thirteenth census, the average value of farm lands throughout the eight states is \$23.28 per acre. The price recorded for the states of Pennsylvania, New York, Massachusetts, Connecticut and Rhode Island was about the same, averaging \$33.92 per acre, while that for the remaining three states, Maine, New Hampshire and Vermont was much lower, averaging \$13.31 per acre.

The apple-growing area in the northeastern states is rapidly extending and comprises much of the cheaper lands of the territory. In New England, the area embraces the southern half of Maine, New Hampshire, and Vermont, projecting somewhat northward along the western border of the latter state, and extending southward to include the greater part of Massachusetts, Connecticut, and Rhode Island. Here the leading varieties in the older orchards are Baldwin, Rhode Island Greening, Northern Spy, Roxbury, Ben Davis, Fameuse, Tolman, Hubbardston, Oldenburg, Red Astrachan, Bethel, Twenty Ounce, McIntosh, Yellow Bellflower, and Wealthy. The later plantings are mostly of higher quality varieties, including Northern Spy, McIntosh, Wealthy, Fall Pippin, Sutton, Wagener, Red Canada, Esopus (Spitzenberg), Gravenstein, Yellow Transparent, Red Astrachan, Fameuse, Tompkins King, and Williams. The Baldwin, however, continues to be the most popular variety in New England.

In New York, the main apple-growing section extends along the south shore of Lake Ontario, but the industry is rapidly developing in many other parts, including the Hudson, Champlain, St. Lawrence, and lower Mohawk valleys, and the lands surrounding the central lakes. The leading varieties in the bearing orchards are Baldwin, Rhode Island, Northern Spy, Tompkins King, Roxbury, Hubbardston, Esopus (Spitzenberg), Golden Russett, Ben Davis, Tolman, Black Gilliflower, Twenty Ounce, Swaar, Westfield, Pumpkin Sweet, Fameuse, Fall Pippin, Yellow Bellflower, McIntosh, Wealthy, Oldenburg, Red Astrachan, Jonathan, Yellow Newtown, Green Newtown, Maiden Blush, Gravenstein, Blue Pearmain, Early Harvest, Alexander, and Yellow Transparent. Many of these varieties are still

being planted, but the tendency is to set fewer varieties and more of the leading commercial sorts.

The apple-growing area in Pennsylvania is limited largely to the southeastern part of the state. The industry has reached its highest development in the Cumberland Valley, especially in Cumberland, Adams and Franklin counties. Much planting is now being done along the upper Susquehanna in Luzerne, Lackawanna, and Wyoming counties. In the southwestern part of the state, Bedford and Somerset counties also have many commercial orchards. Southern Pennsylvania has a longer growing season than New York and New England and this is plainly shown by the nature of the varieties most commonly grown. The older orchards are composed mainly of York Imperial, Baldwin and Northern Spy, but the newer plantings are mostly Stayman Winesap, McIntosh, Delicious, and Northern Spy.

#### *Cultural peculiarities.*

While there is diversity of opinion regarding cultural methods, the common practice embraces a sys-

268. Apple orchard at bearing age, as seen in the northeastern states.

tem of clean culture with cover-crops. In some regions, especially on the heavier soils, it has been found that this treatment, if practised year after year, produces too much growth. In such cases, the cover-crop, instead of being turned under, is allowed to stand till about June, when it is cut and allowed to remain on the surface as a mulch. In New England, clover is most commonly used as a cover-crop. In New York and Pennsylvania, various crops are used for the purpose; among these the most common are clover, vetch, rye, buckwheat, turnips, cowpeas, and soybeans. Some growers in various parts have secured good results from growing their trees in sod, mowing the grass and leaving it as a mulch. The success of this method depends largely on the quantity of herbage that can be grown in the orchard. If the orchard does not produce enough, it must be supplemented with some form of coarse material from other sources. A system of this kind may be very satisfactorily employed in various parts of Pennsylvania, New York and New England, where there is much land that, although well adapted to apple-growing, is oftentimes too steep for cultivation.

As a rule, chemical fertilizers are used in the orchard. Since the supply of humus may be maintained in the orchard by the use of cover-crops, most growers prefer to use the available stable manure for crops like corn, hay, or vegetables, that are not so easily adapted to cover-crop treatment. Stable manure, however, is

often used in sod orchards to supply additional mulch as well as the elements of plant-food. Many growers are coming to realize that the apple tree does not require heavy applications of fertilizers. More important than fertilizers is moisture supply, and this is maintained by increasing the humus and by cultivation. Very few growers are applying much nitrogen, depending upon leguminous cover-crops to keep up the supply. As a source of phosphoric acid, raw ground bone is the most common material. In recent years, very large quantities of basic slag have been used, 600 to 800 pounds per acre usually being applied. Potash is usually applied in the muriate form, but some growers prefer to use the sulfate of potash. Recently, growers have realized the necessity for applying lime, and this is being used largely in the form of ground limestone.

There is a growing feeling that in the past young trees have been pruned too severely. Progressive growers think that the young apple tree should not be pruned very severely during the dormant season. With this is associated the idea that when much pruning is necessary, some of it, at least, should be performed in the growing season. This practice tends to bring the

269. Harvest time in the apple orchard.

trees into bearing earlier and to make better-shaped trees. Summer pruning, when employed, is usually performed about July 1 or just before growth ceases. Mature trees tend to overbear, and pruning them in the dormant season is the rule.

A striking feature in the work of renovating old orchards is the severity with which many of the trees are pruned. High-headed trees, especially those that are very weak, are cut back to mere stubs on which the growth of water-sprouts is encouraged. From these sprouts new heads are formed. Trees treated in this way often produce fair crops of fruit, when properly trained, the fourth or fifth year following the treatment. Other trees that are in better shape to start with, are dealt with less severely, only the higher branches being removed and the remaining ones shortened in.

Spraying practices are about the same throughout the various regions of the Northeast. The concentrated lime-sulfur wash, either prepared or home-made, has become the standard remedy for scale. In some sections and especially for use on old apple trees, the miscible oils are preferred. For the various fungous troubles, of which scab, black-rot, rust and sooty-blotch are the most conspicuous, a weak lime-sulfur preparation is generally employed. Applications are usually made just before the blossoms open, again after the petals fall, and one or two later applications at intervals of three or four weeks. Arsenate of lead is usually added for the control of insects. In New England, the lime-sulfur as a summer spray has not given satisfaction, and the tendency is to use regular bordeaux

mixture for the first application and a very weak bordeaux for the subsequent treatments. With most varieties, and under ordinary conditions, the one application is sufficient to control the various diseases. One or two applications of arsenate of lead, either with or without bordeaux, is usually applied after the blossoms have fallen.

The practice of thinning apples is becoming somewhat general among the commercial growers of New England and in most sections of New York and Pennsylvania. The work is usually performed about July 1, or just after the so-called "June drop." In some sections in western New York, where the evaporating trade takes the greater part of the crop, the practice is almost unknown.

#### Marketing.

The apple crop in general farming districts is mostly disposed of within the limits of the territory and usually in the local market. The more extensive growers, however, ship large quantities to the eastern cities, and varying quantities, depending upon the supply, are exported. Progress in grading and packing has been slow, chiefly because of lack of necessity. There is great demand in the manufacturing centers for a medium grade of fruit and in such places it has not paid to increase the price of apples by fancy grading and packing. Some growers, even at the present time, say that they make as much from their lower grades as from their higher grades. This applies especially to sections where peddlers come to the orchard, take the fruit away and bring the barrels back. The enormous number of varieties has also affected progress in the way of improved methods. Methods of packing and selling are very diverse. The barrel still remains the most popular package, although the box is being largely used. In the vicinity of the large cities and towns, special packages are used for the retail trade. Around Boston, a slatted bushel box is in common use. In Connecticut, the common Jersey peach basket is largely used, with a growing tendency toward the climax basket. Near Philadelphia, the familiar hamper is still in use. The box package as used in the West has been adopted by many growers in New York and in northern New England. In Connecticut, there is a movement to adopt a distinctive package, like the climax basket, for the fancy retail trade and to continue to use the barrel for the general crop.

C. D. JARVIS.

#### The apple in Canada.

Apples have been cultivated in Canada for about 300 years. In the early part of the seventeenth century, the French settlers brought with them seeds and trees to the banks of the St. Lawrence River, along which the first settlements were made. In that part of Canada which in the French régime was known as Acadia, now the province of Nova Scotia, apple trees were planted early in the seventeenth century also. Trees were top-grafted in Nova Scotia as early as 1764, and some of these old trees are still alive. On account of poor transportation facilities in Canada until comparatively recent years, the development of apple-growing was slow for a long time and it has been only during the past fifty or sixty years that a rapid growth in the industry has taken place. Now, however, the production of apples is large and is increasing very fast. In 1911 the number of bushels of apples grown in Canada was estimated at 10,384,985.

#### Regions.

The area in Canada over which apples can be grown is very large. In the provinces of Ontario and Quebec, there is a belt of about 700 miles in length, where apple trees can be successfully grown, while in the province of Ontario alone the best winter apples can be

grown over an area of about 350 miles long by 30 to 150 miles in width. Over this great winter-apple area, which may be roughly divided into, first: that part bordering on Lake Ontario and extending for 30 and more miles inland; second, that bordering Lake Huron and for several miles back; and third, the southwestern part of Ontario,—the Northern Spy, Baldwin, Tompkins King and Rhode Island Greening are the predominant winter varieties of the better class.

Nova Scotia has long been noted for its winter apples, which ship and keep well. The most favored parts are the Annapolis and Cornwallis valleys, which have a total length of about 100 miles and vary in width from 6 to 11 miles. Here apples of British or European origin, such as Blenheim, Ribston, Gravenstein, Cox Orange Pippin, and Yellow Bellflower do particularly well. But it is being found that winter apples can be grown successfully along the southeastern part of Nova Scotia, and a large area will no doubt be eventually planted to apple trees there. In the northern part of Nova Scotia, the harder apples, including some winter varieties, do well. Prince Edward Island, the smallest province in Canada, produces excellent apples, and here may be found, perhaps, the longest-keeping fruit in Canada of the varieties grown, due no doubt to the cool autumn. The season is somewhat short for some of the latest-maturing varieties. The province of New Brunswick has for a long time shown its adaptability for apple-culture, and in this province some of the highest-colored and best-flavored apples are grown. The climate over a large part of New Brunswick is much the same as the southern part of the province of Quebec and eastern and central Ontario, and over this great area such apples as Wealthy, Fameuse, McIntosh, Alexander, Wolf River and others are grown to great perfection.

In the far West, British Columbia has many districts and valleys well suited for summer, autumn and winter varieties of apples, but some varieties do better in one district than in another. At present the three most important parts are, first, that comprising the damp climate of the lower mainland near the coast, and Vancouver Island; second, the dry interior country where irrigation is, as a rule, necessary, including the Okanagan and other valleys; and third, the Kootenays, East and West, the Salmon Arm, and other districts where irrigation is in most places unnecessary. Many valleys farther north than the present commercial orchards extend are being found suitable for apple-culture.

In the prairie provinces of Manitoba, Saskatchewan and Alberta, few apples have as yet been grown, but it is thought that before long some parts of these provinces will be producing large quantities of apples. In southern Manitoba the Russian varieties of apples are succeeding well in places where cared for, and considerable quantities of fruit have been obtained there. The chief causes of failure in the prairie provinces appear to be, first, too late growth, preventing proper ripening of the wood, and due, we believe, to the rich soil with its large percentage of available nitrogen; second, to the drying out of the trees in winter on account of their being exposed to dry and very cold winds for a long period; and third, on account of early growth in spring followed by hard frosts. All of these causes of failure may in a large degree be overcome by planting the hardiest varieties in well-drained, light soil, protecting them from winds in winter by means of windbreaks, and choosing exposures where growth will not start early. In the wooded country in northern Saskatchewan and Alberta, where the springs are cooler and where there is natural protection, it is thought that ultimately large quantities of apples will be grown. At present crab-apples are being grown in a number of places and also the small hybrid apples originated by William Saunders.

The farthest north that apples have been grown in

Canada east of the Rocky Mountains, of which we have a record, is at Fort Vermilion, Peace River, in latitude 56°, where, in 1910, fruit was grown of the hybrid apples referred to.

#### *Varieties of apples recommended for different parts of Canada.*

ONTARIO (districts bordering Lake Ontario and Lake Huron, and southwestern Ontario): *Summer*—Red Astrachan, Oldenburg, Fall—Gravenstein, Wealthy, Alexander, McIntosh, Fameuse, Blenheim. *Winter*—Tompkins King, Rhode Island Greening, Baldwin, Northern Spy, Cranberry, Stark.

NOVA SCOTIA (Annapolis, Cornwallis, and adjacent valleys): *Summer*—Red Astrachan, Oldenburg. *Fall*—Gravenstein, Wealthy, Blenheim, Ribston. *Winter*—Tompkins King, Yellow Bellflower, Wagener, Cox Orange Pippin, Rhode Island Greening, Stark, Northern Spy, American Golden Russet, Fallawater, Roxbury Russet (Nonpareil), and Ben Davis.

NOVA SCOTIA (northern and colder parts) NEW BRUNSWICK, QUEBEC (except coldest parts), EASTERN AND CENTRAL ONTARIO: *Summer*—Transparent, Lowland Raspberry, Oldenburg. *Fall*—St. Lawrence, Wealthy, Dudley, Alexander, McMahon. *Winter*—McIntosh, Fameuse, Wolf River, Bethel, Milwaukee.

PRINCE EDWARD ISLAND: *Summer*—Transparent, Oldenburg, Fall—Wealthy, Dudley, Gravenstein (which keeps well into winter here). *Winter*—Alexander, Wolf River, McIntosh, Stark. Such varieties as Blenheim, Ribston, Tompkins King, Northern Spy, and many others can be grown on Prince Edward Island, but are not so reliable for commercial purposes.

BRITISH COLUMBIA (lower mainland, Vancouver Island): Yellow Transparent, Oldenburg, Gravenstein, Wealthy, Tompkins King, Grimes. For irrigated districts of Southern British Columbia: Transparent, Red Astrachan, Oldenburg, Wealthy, McIntosh, Jonathan, Wagener, Rome Beauty, and in addition for the most favored parts, Esopus, Yellow Newtown, and Winesap. Other temperate parts where irrigation, if practised, is not general, including the Kootenays, Salmon Arm, and Armstrong district: Yellow Transparent, Oldenburg, Gravenstein, Wealthy, McIntosh, Jonathan, Wagener, Grimes and Northern Spy.

Hardest varieties for coldest parts of Canada: *Summer to Autumn*—Blushed Calville, Lowland Raspberry, Oldenburg, Chalamoff. *Autumn to Winter*—Antonovka, Wealthy, Hibernial, McMahon, Longfield, and Patten. *Crab-apples*—Whitney, Virginia Martha, Transcendent, Hyslop and the small hybrid apples originated by Wm. Saunders.

Up to comparatively recent years, Canada had depended mainly on the other parts of the world for varieties to plant, but some excellent apples of Canadian origin are now in commerce, such as Fameuse, McIntosh, St. Lawrence, and Baxter. Within the past twenty years under the direction of the Dominion Government, many new varieties have been originated with a view to furnishing suitable kinds for the prairie provinces, and secondly to obtain apples of the best color and quality which would succeed over a wider range than those on the market at present. The results so far have been very promising.

#### *General outlook.*

Canadians are fully alive to the importance of practising the best methods of apple-culture, and in those parts of the Dominion where the industry is an important one, the methods employed and culture given are equal to those in other countries.

The coöperative movement is strong in Canada, and there are many coöperative associations for the buying of horticultural supplies and for the marketing of fruit. There has been an Act in force in Canada since 1899 by which Dominion inspectors may examine fruit packed in closed packages before shipment in any part of Canada. The Act empowers the inspectors to mark the package "Falsely Marked" if the fruit within the package is not of the grade or quality indicated by the marks outside, and the person who packs the fruit and marks the package is liable to a fine.

There is a minimum standard or legal barrel of 96 Imperial quarts for apples throughout Canada, and a uniform box of 10 x 11 x 20 inches, inside measurements. The barrel is still the popular package in eastern Canada, although the use of the box is steadily increasing. In British Columbia, however, the box is used practically altogether.

The outlook for apple-growing in Canada is bright. The market for Canadian apples appears to be

unlimited, if the fruit is well packed and properly distributed, and the quantity of apples that Canada is able to produce is enormous. For further information, see *British North America, Horticulture in.*

W. T. MACOUN.

**The apple in the southern Alleghany Mountain region. Fig. 270.**

With respect to climatic conditions, the Alleghany region presents the widest range of extremes within short distances in eastern North America. Extending through nearly seven degrees of north latitude, its great

270. The Alleghany apple region.

valleys, plateaus, detached hills and long ridges vary in elevation from 500 to more than 4,000 feet above sea-level, presenting in their varied slopes almost every angle of exposure to the sun. Correspondingly varied soils occur also, often in close proximity, so that within short distances, combinations of soil and climatic conditions adapted to more widely differing types of plants are found than elsewhere in the humid regions of the United States. The extreme contrasts occur in western North Carolina, where in the sheltered valleys and thermal belts of the eastern slopes of the Blue Ridge, the fig and the European grape are grown with a fair degree of success within a few miles of higher lands well adapted to a wide range of winter apples.

While fewer chronological records have been preserved of the earlier history of apple-culture in this region than is true of some of the more northern apple districts, it is evident from scattered references that in some localities in Virginia and North Carolina, rather systematic culture of this fruit was undertaken in a small way at a very early date.

It is known that as early as 1686 there was one apple orchard of 2,500 trees in Virginia, mostly grafted, and that by the close of the seventeenth century, few plantations in that state were without orchards. In these, the apple was the leading fruit along with the peach, the pear, the plum, the quince and some others. As early as 1773 Thomas Jefferson recorded in his "Garden Book" the grafting of "Newtown Pippin" in Albemarle County, Virginia, and in 1778 the planting of these grafted trees on his Monticello estate. This variety had apparently reached that section from the vicinity of Philadelphia as early as 1755 in the form of cions brought in the saddle-bags of Dr. Thomas Walker, the commissary officer of the Virginia troops in Braddock's army, when he returned after the disastrous defeat of that year. (See Bulletin 5, Division of Pomology, U. S. Department of Agriculture, p. 360.-1898.)

But if written records were entirely lacking, the large size and evident age of the surviving trees about farm dwellings and the abundant distribution of seedling apple trees of great age and large size at the present time would sufficiently establish the fact of early introduction and the general adaptability of the conditions to the requirements of the apple. The late T. K. Bruner, of North Carolina, cites an example of an

orchard in Haywood County in that state in which, though never cultivated, a hundred trees had attained a size of full 3 feet in diameter of trunk, the largest having a girth of 11 feet and 9 inches. While these exceptionally large trees are usually found in the lower slopes or in mountain coves where the wash from the mountainsides above brings to them the moisture and fertility of considerable areas of land, many unoccupied benches and gradual slopes exist where such soil conditions could be approximately duplicated by the orchardist.

*Varieties of the Alleghany region.*

While less attention has probably been given in this region to the systematic study of the seedling fruits that have originated there than in most of the earlier settled parts of the country, upwards of fifty varieties of the 319 included in the last catalogue of fruits of the American Pomological Society are traceable to this region. These include such commercially important varieties as Ben Davis, Grimes' Golden, Kinnard, Paragon and Willow, together with such highly esteemed home-use sorts as Bonum, Buckingham, Gilpin, Pilot, Red June, Shockley, Summer King, Terry and Virginia Beauty. R. L. Watts, working in Tennessee, and C. C. Newman, in South Carolina and Georgia, have made a beginning in the canvass of the region for valuable seedlings in connection with their experimentation work, but this region undoubtedly remains at the present time the most promising field in America for the searcher after promising new varieties of apples.

As in most of the earlier settled parts of the country, commercial development of orchards in this region is comparatively recent. The first plantings were solely for home-supply. Later, small orchards were planted for the production of sun-dried apples, cider, apple-brandy and similar products in a commercial way, rather than for the sale of the fresh fruit on any extensive scale. So long as these uses determined the selection of trees for planting, little attention was paid to varieties, or, in fact, to the perpetuation of varieties at all; hence the numerous small seedling orchards persisting throughout the less accessible portions of the region at the present time. Gradually, in certain localities, the quality of fruit produced gave the more durable winter varieties a money value for marketing by wagon, river-boat or railroad to more distant markets. The longer-keeping Winesap and other winter apples of Tennessee found profitable wagon-market demand in the lower valleys of Alabama and Georgia where this

271. A mountain orchard, Virginia.

fruit did not succeed. The Willow, Gilpin and Bentley of the northern Panhandle of West Virginia found eager buyers when transported by boat down the Ohio and Mississippi Rivers as far as New Orleans. The Yellow Newtown, rechristened Albemarle Pippin in the county of that name (under the impression that it was a dis-

tinct sort) found its way from Virginia by railroad to the eastern seaboard cities and at an early date moved across the Atlantic in considerable quantities, where its durability and fine dessert quality created an active demand at prices that yielded a good profit to the grower.

#### *Extent of the planting.*

Gradually commercial orcharding has been differentiated from ordinary farm fruit-growing and a considerable number of farms have become distinctively orchard farms on which the apple is the main crop, with merely such cereals and forage crops as can be grown without interfering with the essential orchard operations, such as orchard cultivation, spraying, harvesting, and the like.

Most of the systematically planted and cared for orchards are under thirty years of age and a large proportion of the acreage in these has been planted since 1900. Accurate statistical information regarding the acreage or number of trees of orchard fruits in the United States is lacking, and this is peculiarly true of those regions in which, because of varying topography and the resulting eccentricities of climate and variations in soil, the orchard areas vary greatly in size and form, as is true of much of this region. Outside of the Great Valley of Virginia, and Tennessee, and those portions of the Piedmont region of Virginia that are adapted to orcharding, most of the best orchard sites occur as coves, benches or broken slopes, possessing at the same time suitable depth and character of soil, and adequate atmospheric drainage. (Figs. 271, 272.) Some of the best orchards are strung out along the lower slopes, varying in width in accordance with particular soil types. This is especially true of the "pippin orchards" in the Blue Ridge district of Virginia and North Carolina where certain particular combinations of soil and slope are considered important for the Yellow Newtown.

The following summary of the number of trees, both bearing and non-bearing, and of yield and value of crop in the eight states comprised in the region, is compiled from the advance sheets of the census of 1910:

APPLE IN SOUTHEASTERN UNITED STATES, CENSUS OF 1910.

	Trees, April 15, 1910		Product, 1909.	
	Of bearing age	Not of bearing age	Bushels	Value
United States ..	151,323,000	65,792,000	147,522,000	\$83,231,000
Virginia .....	7,005,000	3,436,000	6,104,000	3,130,000
W. Virginia .....	4,571,000	2,772,000	4,225,000	2,461,000

Georgia .....	1,878,000	822,000	896,000	556,000
Alabama .....	1,468,000	738,000	888,000	621,000
Tennessee .....	4,839,000	2,117,000	4,640,000	2,172,000
Kentucky .....	5,538,000	2,106,000	7,368,000	3,067,000
	30,791,000	14,095,000	29,260,000	\$14,298,000
	20 per cent	20 per cent	19 per cent	17 per cent

It will be observed on comparison of these tables with those of the United States as a whole that this region is credited with approximately 20 per cent of both bearing and non-bearing trees, and that the product of the region in the crop year of 1909 was of somewhat smaller proportion (19 per cent) and value (17 per cent).

#### *Outlook for the Alleghany region.*

In contrast with the more northern apple districts, most of this region was until recently somewhat at a disadvantage so far as commercial production is concerned. Higher humidity favored the development of certain injurious diseases in foliage and fruit; the warmer weather commonly prevalent in autumn accelerated

ripening and therefore shortened the storage durability of the fruit; relatively long hauls from orchards to railroad station over rough roads resulted in much bruising and, by prolonging the exposure of the fruit to the weather, still further impaired its keeping quality. The development of efficient remedies and spraying equipment, and the improvement in methods of handling the fruit, coupled with the marked improvement in roads that has been accomplished in many sections is rapidly changing this. The railroads also, in recognition of the need have accelerated and improved their ser-

272. Apple orchard in Piedmont region of the Alleghenies.

vice so that certain parts of the region are handling their apples as well as the best eastern or barrel-fruit districts, and better than in much of the older commercial apple territory.

The conspicuous essent als of success in orcharding in this region, as in others, are:

(1) *Suitability of site*, as regards character of soil and adequacy of atmospheric drainage.

(2) *Adaptability of varieties to the soil and climate of the location.*—

The standard northern varieties, though growing and frequently bearing well, are unreliable in most localities, especially below elevations under 200 feet, although in certain localities succeeding well under careful management. The thoroughly proved and distinctively important commercial sorts of the region are York Imperial, Winesap, Stayman Winesap, Kinnard, Ben Davis, Yellow Newtown, Grimes, Willow and Rome Beauty. In some sections less well-known sorts, such as Paragon, Arkansas (syn. Mammoth Black Twig), Bonum, Virginia Beauty, Lowry, Shockley, and Terry, are considerably planted in commercial orchards.

Gano, Delicious, Jonathan and some other sorts of Mississippi Valley or northern origin are promising in certain localities, but these have not yet been sufficiently tested to justify extensive planting.

Summer varieties, though succeeding well throughout most of the region and universally found in sufficient quantity for home use, have not become so important commercially as in the lower lands of the tidewater districts and of the Mississippi Valley. This is in a large measure due to the earlier ripening of the fruit at lower elevations, which frequently gives it a distinct advantage in northern markets. Recently, considerable plantings of Yellow Transparent, Williams, Oldenburg, Gravenstein and some other sorts have been made in the more northern districts of the region, especially in West Virginia and western Maryland.

(3) *Abundance of water for spraying.*—The necessity of thorough and systematic spraying of orchards to protect against insects and fungi makes the orchard water supply an important factor. In many places, flowing springs are available at considerable elevations from which the supply can be piped by gravity to convenient mixing stations, thus permitting prompt distribution without long wagon haul of liquid. The use of compressed-air spraying-outfits, charged at conveniently located air-compressing and spray-mixing stations, has developed more largely in the lower Shenandoah Valley part of this region than elsewhere, but the gasoline engine is the prevailing type of equipment.

(4) *Adaptability of land to cultivation.*—While occasional orchards in this as in other humid regions do well without systematic tillage, especially if heavily mulched with stable manure, straw or other humus-producing material, annual or at least alternate-year plowing and cultivation, supplemented by leguminous crops, is rapidly becoming the generally accepted best practice of the region. Some sites otherwise admirably adapted to apple-growing are too rocky or too steep to plow, and therefore of doubtful value to the orchardist. Much can be done on such sites by contour-terracing, however, both to dispose of loose rocks and to reduce washing of the slopes, thereby conserving the soil moisture against droughty periods.

(5) *Adequacy of transportation facilities.*—This includes both railroads and highways. Some of the earlier-planted commercial orchards were located as much as 15 to 25 or even 30 miles from the shipping station. The expense incident to this long haul and the ill effect of the jolting and exposure of the fruit to the weather are evident. Every additional mile beyond a distance of 3 miles from the station over a good road is a handicap which the orchard

planter should avoid unless it is overbalanced by other important advantages. As roads are improved, the practical distance will increase.

Several of the State Experiment Stations, as well as the United States Department of Agriculture and the North Carolina Department of Agriculture, have published bulletins bearing on different phases of apple-orcharding, especially Maryland, Virginia, West Virginia, Tennessee, and South Carolina.

WM. A. TAYLOR.

### The apple in mid-continental or plains districts.

In that vast region of the interior of the United States which lies between the Great Lakes, Ohio, Kentucky, and Tennessee on the east and the Rocky Mountain states on the west, the Canadian boundary on the

in the valley of the Red River of the North and a rather narrow strip along the northeast boundary lies in the basin of the Great Lakes.

The larger part of this mid-continental district, as outlined, has an elevation of 500 feet to 2,000 feet above sea-level. The southwest point of Indiana, southern Illinois, southeastern Missouri, and eastern Arkansas have an elevation of less than 500 feet. The remainder of Indiana and Illinois, much of Missouri, and a portion of southern and eastern Iowa lie between 500 feet and 1,000 feet elevation. The range of elevation of 1,000 to 2,000 feet takes in the remaining parts of Iowa, most of Minnesota, and the eastern part of the Dakotas, Nebraska, Kansas, Oklahoma, and the Ozarks. The remainder lies to the west in the Great Plains Plateau at an elevation above 2,000 feet.

In the more northern and western districts of this region, there is little or no commercial orcharding.

Only in their more favored localities are apples produced at all, and the lists are restricted to the hardier varieties. This is because the recurring extremes of temperature and of drought make the environment unfavorable to the apple, at least during critical periods. But throughout the states of the corn-belt, the apple is very generally grown for home use and certain sections show a notable development of commercial orcharding (Figs. 274, 275). In fact, the most extensive individual apple orchards known are found in parts of Arkansas, Missouri, Kansas, and Illinois, some of them being several hundred acres in extent.

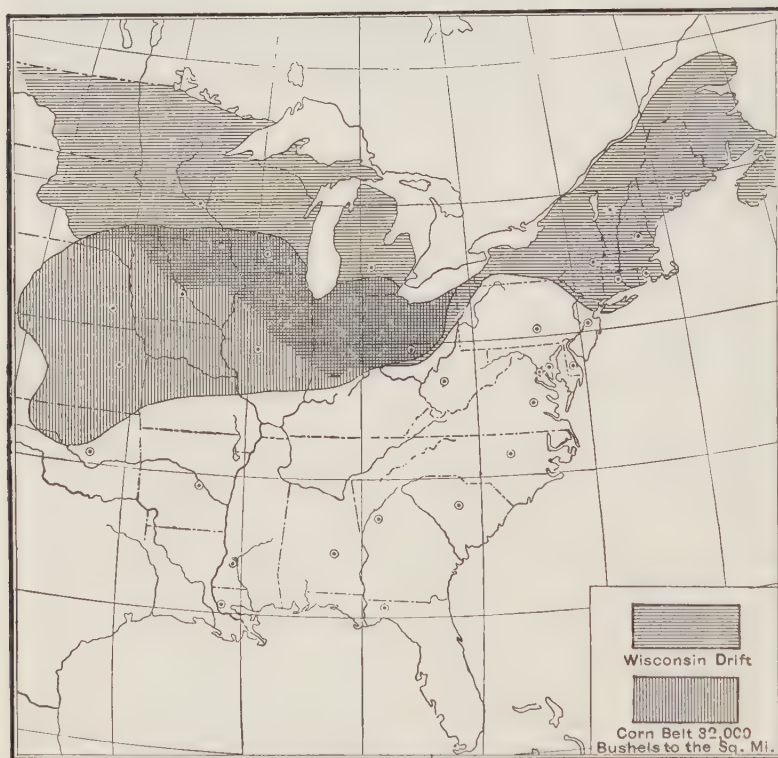

Orchards well located and rightly managed are proving to be profitable in different sections of the corn-belt states. With the rapid growth of the United States in population and wealth, must come a corresponding increase in the home-market demand for good apples at remunerative prices. This, with the improvement and extension of storage and transportation facilities and the contemporaneous expansion of our foreign trade, tends to make the outlook encouraging for the apple-growing industry in this region. The more general adoption

of up-to-date methods of marketing and of orchard management will help to put the industry on a more stable basis, and gradually to enlarge it and extend it.

### Rank in apple-production.

According to the United States census reports of 1910, approximately 40 per cent of the bearing apple trees of the United States is found in the territory above outlined, together with 33 per cent of the young trees not yet of bearing age. In the census year of 1909, it produced approximately one-fourth of the apple crop of the entire United States.

Following is a list based on United States census reports, which indicates something of the relative standing. For comparison they are also ranked as to their averages in apple-crop production for 1905, 1907, and 1909, combined on the basis of the crop reports published in the American Agriculturist Yearbook:

273. The mid-continental corn-belt, in which the apple is the leading fruit; and the Wisconsin drift, on which the Ben Davis family is not at its best.

north and the Gulf states on the south, the leading fruit is the apple. This mid-continental territory includes the greater part of that exceptionally rich agricultural region which has come to be known as the corn-belt of America. (Fig. 273.) It extends also into the northern wheat-belt of the Upper Mississippi Valley plains and into the wheat and livestock country of the Great Plains Plateau of Oklahoma, Kansas, Nebraska, and the Dakotas.

### Geography.

The topography may be indicated in a very general way by the statement that this region takes in the Upper Mississippi Valley plains, a large part of the Great Plains Plateau, and all of that more limited area known as the Ozark Plateau. Its great river valleys are those of the Ohio, Mississippi, Missouri, Arkansas, and Red. A limited area in Minnesota and the Dakotas lies

### Apple belts.

In comparing the great apple-growing regions of the continent it is convenient to designate each by its leading variety. In the eastern part of the continent, there is the Fameuse or Wealthy belt on the north, the Ben Davis belt on the south, and the Baldwin belt lying intermediate between these two. It is seen that varieties differ greatly as to their adaptability to different regions. The degree of soil aeration and of soil moisture and the range of atmospheric and soil temperatures are among the most important determining factors of the geographical range of commercial apple-growing with any variety.

274. Apple areas in the Mississippi Valley—Yields, 1909 crop.

Passing westward into the mid-continental region, it is found that the Baldwin belt does not extend west of Lake Michigan. The climatic extremes are here too severe for that variety and many of its eastern associates of a similar degree of hardness. In

all that vast territory which extends westward from the Great Lakes, these varieties disappear and do not again appear till the states of the Pacific Coast are reached. Instead, the Wealthy belt extends southward till it reaches the region where Wealthy yields leadership to Ben Davis. In this connection it is worthy of note that from the Atlantic Coast westward to the Missouri River the north margin of the Ben Davis belt approximately coincides with the southern boundary of the geological area covered by the Wisconsin drift. (Fig. 273.)

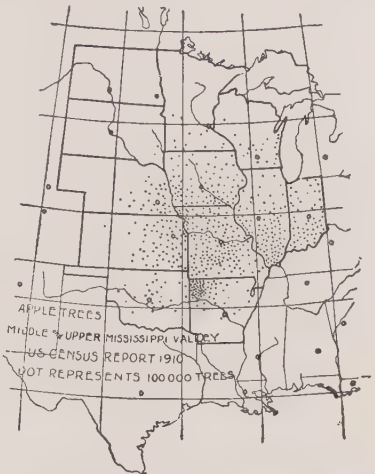

*Wealthy belt.*—The mid-continental territory in which Wealthy is, generally speaking, the leading variety, includes northern Illinois, the north half of Iowa, and practically all of the apple-growing districts of Wisconsin, Minnesota, South Dakota, and northern Nebraska. Among the more important varieties associated with it are, for the more northern parts, Oldenburg, Okabena, Patten (Patten Greening), and Malinda. Among the very hardiest of the large-size apples for the North are those of the Hiberna group, but their fruit is so austere that it is esteemed of little value except for culinary uses. In the southern part of the Wealthy belt are grown hardy varieties of more or less local value such as Salome, Windsor, Black Annette, and Colorado Orange, varieties which as yet have not established themselves in the great world markets but which are valued where better varieties cannot be satisfactorily grown.

*Ben Davis belt.*—Generally speaking, Ben Davis is the leading variety in central and southern Illinois, the south half of Iowa, and the apple-growing districts of Arkansas, Oklahoma, Missouri, Kansas, and the south half of Nebraska. With its close kin, the Gano and the Black Ben Davis, which evidently are highly-colored bud-sports of Ben Davis, it probably produces at least one-half of the commercial apple-crop in this region. Winesap and Jonathan appear to be next in order of importance, with Winesap perhaps in the lead. Other important varieties are Grimes, Rome Beauty, Willow (Twig), Missouri (Pippin), Minkler, and Ralls. York Imperial is gaining ground. Stayman Winesap is one of the newer kinds which will be more largely planted. Delicious, also, is attracting attention, particularly because of its agreeable dessert quality and good appearance. The Stayman and Delicious are being planted to some extent in the southern part of the Wealthy belt, as Jonathan and Grimes have been.

### Varieties.

The following varieties of apples are those most commonly grown in the prairies and plains regions:

Arkansas (Mammoth Black Twig).	Jonathan.	Salome.
Ben Davis.	Minkler.	Stayman.
Black Ben Davis.	Missouri.	Wealthy.
Gano.	Oldenburg.	Willow (Willow Twig).
Grimes Golden.	Ralls (Ralls Genet.	Winesap.
Ingram.	Geniton).	Yellow Transparent.
	Rome Beauty.	York (York Imperial).

275. Apple areas in the Mississippi Valley—Trees.

*Status of the apple industry in the mid-continental states.*

**Wisconsin.**—Apples are grown mostly in small plantings about homesteads. The crop is important chiefly in supplying the home and the local markets with summer and fall fruit. The varieties are those of the Wealthy belt.

**Minnesota.**—Apple-growing is chiefly confined to the southeastern quarter of the state, although crab-apples and the very hardiest apples are being planted in other sections. From Minneapolis southward to the Iowa line, many farm orchards are found and some commercial plantings. Heretofore, these have seldom produced enough fruit to supply the local demand at any time and then for a brief period only. However, apple-production is gradually increasing in the state and apple-planting is being slowly extended. It will doubtless assume greater proportions as late-keeping varieties are developed which are hardy and desirable.

**North Dakota.**—This state raises but very few apples or crab-apples and those only of the kinds most resistant to cold and drought. It ranks next to the bottom of the list in apple-production among the states of the Union.

**South Dakota.**—Apples are produced in very limited quantities and chiefly near the Missouri River in the southeast corner of the state and in the Black Hills district. The varieties are those of the northern section of the Wealthy belt. The recommended list of the State Horticultural Society includes: Northern District—first degree of hardiness—Hibernal, Oldenburg (Duchess); second degree of hardiness—Patten (Greening), Anisim, Wealthy. Southern District—in addition to the above—Northwestern Greening, Malinda, and, in favorable locations, Ben Davis. Planting increases slowly.

**Nebraska.**—Apples are grown in the eastern third of the state and under irrigation in some places farther west. It has some important commercial orchards, the majority of them being in the southeastern part of the state and within three counties of the Missouri River. The northern third of the state grows the varieties common to the Wealthy belt. In the southern two-thirds are grown the Ben Davis and its kin and also Winesap, Grimes, Arkansas or Mammoth Black Twig, Jonathan, Missouri (Pippin), Willow (Twig) and others of the Ben Davis associates. Planting is not active, but growers are beginning to take a more lively interest in modern methods of orchard management.

**Iowa.**—In the amount of crop produced, Iowa was ranked sixth in the Union by the 1910 census, but often it drops as low as the eighteenth or nineteenth place. The greater proportion of the crop is grown in home orchards and goes to supply home and local market demands, but in the aggregate there is a considerable number of commercial orchards. These are found in all parts of the state. They are sparsely scattered in the north and gradually increase in number to the southward, being most abundant in the south tier of counties. The most important commercial apple district includes the counties bordering the Missouri River in southwestern Iowa. Here Grimes and Jonathan of superior quality are grown. Northern Iowa grows the varieties of the Wealthy belt. The southern Iowa list is almost identical with that given for southeastern Nebraska. Planting is not active. Modern methods of management are being adopted by a few of the more progressive growers but most orchards suffer from neglect.

**Illinois.**—At present, Illinois takes second rank in apple-production among the mid-continental states, being surpassed by Missouri only. Northern Illinois, like Wisconsin, grows apples chiefly for home use and the varieties are those of the southern area of the Wealthy belt. Central and southern Illinois contain altogether many large commercial apple orchards. In

good-crop years, they produce in the aggregate large quantities of winter apples, including Ben Davis, Black Ben Davis, Gano, Arkansas or Mammoth Black Twig, Winesap, Jonathan, Grimes, Missouri, Willow, Ralls, and several other varieties commonly found in the Ben Davis belt. Winter injury and late spring freezes have often seriously diminished the general crop. Injurious insects together with blight, cankers, bitter-rot, blotch, scab and other diseases, have also caused great losses. Clean tillage and other up-to-date orchard methods would doubtless be more generally practised if crops were more reliable. Planting is not very active, although the number of trees of bearing age is gradually increasing.

**Missouri.**—The 1900 census gave Missouri ninth rank and the 1910 census gave it fourth rank in apple-production, but it often falls as low as the sixteenth place among the states of the Union. On the whole, it may be regarded as the leading apple state of the mid-continental region. Apples are very generally grown for home use and local market throughout Missouri, but the more important commercial apple districts are in the Ozark country of southwest Missouri and the loess soil region along the Missouri River in the northwest quarter of the state. The apple industry in Missouri has been retarded by troubles similar to those described for Illinois, but undoubted progress is being made in knowledge of the methods for holding them under control.

**Arkansas.**—The apple districts of Arkansas are mostly located in the northwest third of the state, particularly in the two northwest counties of Benton and Washington, which have from four to five million trees planted. There is also an undeveloped west-central region. The older plantings include about 90 per cent Ben Davis, Arkansas or Mammoth Black Twig, and Winesap. The later plantings are made up principally of Gano, Black Ben Davis, Jonathan, Grimes, Winesap, Stayman Winesap, with some Ingram, Collins, King David, and Delicious. Arkansas has enough apple trees of bearing age to produce a very large crop, but as in Missouri and Illinois, within recent years unfavorable climatic conditions with diseases and injurious insects have proved a rather serious handicap to the progress of the apple industry. Generally speaking, planting is not now being rapidly extended. The planting of thousands or even hundreds of acres under one management is fortunately no longer generally regarded with favor, and the trend is distinctly towards reducing the individual holdings to a size that is compatible with careful and thorough orchard management. The future will see a large development of commercial apple-growing in this region.

**Kansas.**—Northeastern Kansas from Topeka northward to the Nebraska line and northeastward to the Missouri River forms a part of an important apple-growing region which takes in southeastern Nebraska, southwestern Iowa, and northwestern Missouri. Here Jonathan and Grimes are grown to a high degree of perfection, together with Ben Davis, Gano, Winesap, and other varieties of the Ben Davis belt. There is another important apple district which is located in the Arkansas Valley from Hutchinson to the Oklahoma line. In recent years, this has taken the lead in crop-production in this state. The older Kansas orchards were largely of Ben Davis, Gano, and Missouri. The newer plantings have more of York Imperial, Jonathan and Grimes. Other varieties common to the Ben Davis belt are also found.

**Oklahoma and northwest Texas.**—In Oklahoma, the apple has not yet developed very large commercial importance. Planting is gradually increasing in the Red River section and also in west Texas where the altitude reaches 2,000 feet. Here Ben Davis, Missouri and Arkansas Black are among the most important commercial varieties.

*Establishing and managing the orchard on the prairies and plains. Fig. 276.*

**Preparation of land.**—The fundamental principles of proper preparation of soil for orchard planting in the mid-continental country are much the same as those that are set forth for other regions, although they may differ somewhat in relative importance. One of the first things to be considered is the matter of putting the soil in such condition that the entire root-system of the apple tree may withstand, without injury, any period when the soil is filled with water. Unfortunately, the importance of this is not generally nor fully realized, even among experienced orchardists. The principle that apple roots must have a constant supply of air in order to do their work should never be lost sight of. Stagnant water cuts off the supply of air to the roots and very quickly impairs the health of the root-system. Excepting on such soils as deep porous loess, or when the subsoil is of such a sandy or gravelly nature as to

It is well to grow grain or some cultivated crop on the land the season previous to planting the orchard. The land may then be fall-plowed to a good depth and disked in the spring, or it may be plowed in the spring and disked just before planting. North of the latitude of southern Iowa, spring planting is always to be preferred, while to the southward, orchards may be planted either in fall or spring. In the case of fall planting, two or three furrows should be turned towards the tree on each side of the row as a matter of protection from alternate thawing and freezing about the roots and to turn away surface water from the trunk.

In planting the tree it is essential that the first earth that is put in the hole should at once be tramped about the roots, and this process repeated as the hole is filled. Great care must be taken in this region to keep the trees from drying out in handling them while they are being transferred from nursery to orchard. Trees should be kept perfectly dormant till planted. Nursery stock should be neither accepted nor planted after its buds have started growth. Sometimes when such stock is transferred promptly from nursery to orchard on a rainy day, it may grow well, but as a rule it dies or makes but feeble growth.

Budded apple trees should not be planted in any part of the upper Mississippi Valley for the reason that when such trees are set in the orchard the point of union between the top and the seedling root comes at or near the surface of the ground, thus exposing the root to greater liability of suffering winter injury than when it is buried more deeply. By using a long cion grafted on a short piece-root, it is possible to produce a nursery tree that will permit of planting the seedling root deeply. During the history of apple-growing in the more northern parts of the mid-continental apple districts, it has repeatedly happened that when the harder cultivated varieties have been budded on some tender seedling roots, the roots have been winterkilled, while the top remained uninjured until it died from the lack of live roots to support it. In many cases when root-grafted trees of the very hardy varieties had sent out roots from the lower part of the cion, they were able to withstand the severest winters uninjured, while trees of the same kinds which were not thus established on their own roots died from winterkilling of the roots. Such experiences have led fruit-growers to demand root-grafted apple trees.

The methods of spraying now being followed by the more intelligent and progressive apple-growers of mid-continental America do not differ materially from those of the best growers east and west.

**Pruning.**—Pruning is, generally speaking, sadly neglected by the ordinary apple-grower. In recent years, the tendency of orchard practice in the Mississippi Valley has been towards the methods of heading and pruning apple trees which are most commonly practised in the intermountain and Pacific coast districts. Very high-headed trees are comparatively scarce except in old closely planted orchards in which the lower limbs have been lost by over-crowding. The trees are headed rather low, commonly at about 18 to 24 inches from the ground to the first limb. The leader is taken out at a height of 28 to 36 inches, leaving for the framework of the tree from three to five ascending main limbs which should be at least 6 inches apart. In regions where the trees are comparatively short-lived or with varieties that are not expected to live more than from twenty to thirty years, this is doubtless the best practice, but with longer-lived trees it is open to the very serious objection that when loaded with fruit or weighted with ice and snow these large limbs sometimes break at the trunk, leaving an injury which can never be healed, and as a result the whole tree goes down within a few years. On the other hand, trees that are trained with a central leader may lose very large branches and yet heal over such wounds and live

276. A ten-year-old Nebraska apple orchard.  
The trunks are protected from the sun by board jackets.

let the surplus water pass off readily, it may be laid down as a general principle that thorough tiling is fundamental to the highest degree of regular and abundant crop-production and longevity of the apple tree. On land where the general slope is sufficient to carry off the surface water and even on hillsides, tiling may be, and often is, essential to the best success. The lines of tile should be not less than 4 rods apart and in many cases 2 rods apart gives enough better results to more than repay the extra expense. Even in arid regions, progressive orchardists are learning that, under irrigation, in many places it becomes necessary to under-drain the land so as to prevent the seepage and waste-water from water-logging the soil and damaging the root-system of the trees.

**Humus.**—It is highly important that the orchard soils have an abundance of humus to begin with, and that the supply be continually kept up by the use of either green manures or barnyard manure or both. The humus not only puts the soil in a more fertile condition but increases its moisture-holding capacity and gives it greater ability to withstand drought. The necessity of promptly getting rid of surplus water in the soil has already been emphasized. It is equally important to conserve soil moisture so as to carry the tree unharmed through any periods of drought that may occur either in summer or winter. Generally speaking, this can best be done in the mid-continental regions by thorough tillage during the growing season, followed by the growing of cover-crops. In places where soils wash so badly that this practice cannot be followed, perhaps the next best way to develop the capacity of the soil to hold moisture is by the use of barnyard manure and the growing of clovers or other crops that can be mowed twice or more during the season and allowed to rot on the ground.

to old age in good condition. In training trees in this way, it is best to cut off the leader at the proper height when the tree is planted. This tends to force the growth of the branches which are needed to form the main framework of the tree. One of these branches may be allowed to grow in the center of the top so as to form a new leader.

Aside from shaping the tree so as to give it right mechanical framework for supporting heavy loads of fruit, it needs to be kept sufficiently open to permit light and air to reach the foliage throughout the top. This will favor the best development of abundant and strong fruit-buds and perfect fruit. It also leaves the top open so that all of its foliage and fruit may be readily sprayed. Thick, dense tops are to be avoided and trees should not be allowed to grow so close together as to crowd each other.

*Tillage.*—As before stated, the best system for general practice in conserving soil moisture and fertility is tillage throughout the growing season, till late July or early August, followed by a good cover-crop. The greatest care must be used not to bruise the trees when cultivating. In this interior climate, it often happens that such wounds do not readily heal and they may result in the loss of the tree within a very few years. If a wound happens to be made, the loose bark should be at once cut away and the exposed surface coated with a thick paint of pure white lead and raw linseed oil and kept thus protected till completely healed over.

*Mice and rabbits.*—For the last few years in the writer's experience, lime-sulfur sprayed on the trunks and low branches of the trees as soon as the leaves drop has prevented attacks of mice and rabbits. Use at same strength as indicated for the dormant season.

*Handling the crop.*—At the present writing, the apple crop of the mid-continental regions is marketed locally, either in bulk, open packages, or in barrels, or it is shipped in barrels or in bulk. Box-packing is practically unknown here. It is just beginning to be practised by a few scattering enterprising fruit-growers. It would extend more rapidly but for the fact that very few persons in this region know how to pack apples in boxes. The Iowa Experiment Station has taken the lead in introducing box-packing among the apple-growers of the interior by arranging for schools of instruction in apple box-packing in that state and assisting in introducing them into other states. The effect of this work is already shown in the rapidly growing local interest in improved methods of grading and packing apples for market.

The methods followed in barrel-packing and in handling apples in bulk do not differ materially from those which are prevalent in the eastern states. So also the handling of apples in cold storage follows the general lines of this business as practised by eastern growers and dealers, but the storage facilities are not yet developed as extensively as in eastern apple-growing sections, although many strictly up-to-date storage establishments are found.

*Fruit-growers' organizations.*—There are as yet comparatively few apple-growers' organizations in this mid-continental region. Generally speaking, these are organized along lines similar to those which characterize the fruit-growers' organizations of the Rocky Mountain and Pacific coast states, except that in no case are they yet combined in a fruit-growers' exchange. With the increase of intensive orcharding, it may reasonably be expected that apple-growers' organizations in this region will become more abundant and more thoroughly systematized.

*Orchard-heating.*—The recent advent of the practice of fighting late spring frosts by orchard-heating undoubtedly marks a new era in fruit-growing in the mid-continental regions. It reduces the hazards by bringing an heretofore uncertain factor under some degree of

control and thus puts the industry upon a more stable basis.

The amount of losses in this region during only the past decade from injury to orchard blossoms and fruits by late spring frosts and freezes aggregates an enormous sum, a considerable part of which doubtless might have been saved by proper orchard-heating. In the Iowa Horticultural Society Report for 1910, Laurence Greene estimates the amount of loss from frost injury to the apple crop of Iowa alone from 1905 to 1910 at \$5,000,000 to \$10,000,000. In some of the other states, the losses have been even greater.

The practice of orchard-heating for this region is in many respects still in the experimental stages, and much will need to be learned before all the details shall have been definitely worked out into the most efficient and economical practice. Nevertheless, it may now rightly be regarded as a good method of insurance against frost injury.

For detailed treatment, see *Orchard Protection*.

S. A. BEACH.

### Apple-growing in the western mountain states.

Accepting the common geographical grouping of the states, the mountain division embraces the states of Colorado, Idaho, Montana, New Mexico, Utah, Wyoming, Arizona and Nevada. According to the census report, these states produced in 1909 a little less than 4 per cent of the total apple crop of the United States, or 5,600,000 bushels. While New York alone produced four times this amount, and the New England states more than 19,000,000 bushels, these mountain states are competitors worth considering in commercial apple-growing. In 1910, these states reported only 40 per cent of their total acreage of apple orchards in bearing, while the New England states, as well as New York, reported about 80 per cent of their apple trees of bearing age.

#### *The mountain states.*

In the two years that have passed since these figures were gathered, at least five of the mountain states have greatly extended the plantings of apple orchards, and it is safe to say that in no group of states is the apple industry growing more rapidly. Of this group, Colorado stands first in production, Idaho second, Utah third, Montana fourth and New Mexico fifth. In total acreage planted to apple trees, Colorado ranks first, Idaho second and Montana third. Colorado has a substantial lead and promises to hold its place for some years to come. Comparing Utah and New Mexico, it would be unsafe to say which leads in total acreage of apple orchards. The same is true of Arizona, Nevada and Wyoming. The fruit-growing industry of the region has grown up in comparatively recent years and, with the exception of Arizona and Nevada, all states reported the larger per cent of the apple trees too young to bear in 1910. The status of the apple-growing industry in these states individually may be briefly summarized as follows:

*Colorado.*—In 1910, Colorado reported 1,688,000 apple trees of bearing age and 1,973,000 trees not bearing. In 1909 the state produced, according to census figures, 3,559,000 bushels of apples. The state's principal apple-growing sections are the Grand Valley (Mesa County); the North Fork Valley (Delta County); the Uncompahgre Valley (Montrose County); the Cañon City district (Fremont County); and a new and promising district embracing a large part of Montezuma County. The varieties most largely grown are Gano, Jonathan, Rome Beauty and Winesap. In the older orchards, there has been a considerable planting of Ben Davis, but many of these are now grafted to the better varieties. Little is done in the way of apple-growing without irrigation. Most of the orchard land

is found in comparatively narrow mountain valleys or upon the bench or mesa lands of these valleys.

*Idaho.*—In 1910, Idaho had 1,006,000 apple trees of bearing age and 1,540,000 trees not bearing. The state is credited with the production of 660,000 bushels of apples in 1909. The Snake River Valley is the principal apple-growing section. In the north of the state, the Clearwater Valley and the valleys of the Kootenai and Clarke's Fork of the Columbia afford additional possibilities for commercial apple-growing. The industry is growing rapidly, and it is probably safe to say that in 1913 the output of the state was double that of 1909. The principal varieties grown are Gano, Jonathan, Winesap and Rome Beauty, with Esopus and Yellow Newtown in the newer plantings. In the northern half of the state, the moisture supplied by natural rainfall is generally sufficient to mature the apple crop, while in the southern half of the state additional moisture must be supplied by irrigation.

*Montana.*—In 1910, Montana had 697,000 apple trees of bearing age and 1,308,000 trees not bearing. The estimates of the State Board of Horticulture placed the total acreage of apple orchards in Montana, in 1912, as 30,000 acres. The principal apple-growing sections are the Bitter Root Valley, the Flathead district, which embraces a portion of the valley above Flathead Lake and the land along the lake shore, the Clarke's Fork Valley (Carbon County) and the Yellowstone Valley (Yellowstone County); with newer plantings in the valley west of the junction of the Missoula and Flathead Rivers (Missoula and Saunders Counties) and in the Tobacco Plains and Kootenai Valleys in Lincoln County. With the exception of the greater portion of the Flathead districts, all are irrigated. The principal varieties grown are McIntosh, Wagener, Rome Beauty, Northern Spy and Wealthy. A few Gano, Jonathan and Delicious are being planted. The Transcendent Crab, largely planted in the older orchards and those just coming into bearing, is being little planted now, on account of its susceptibility to pear blight.

*New Mexico.*—The apple industry of this state is comparatively young. In 1910 there were 543,000 trees of bearing age and 914,000 trees not bearing. In 1909, the state produced 417,000 bushels of apples. The orchards are all under irrigation and are located in the Rio Grande Valley from north of Albuquerque to the Texas line, in the Roswell district in the Pecos Valley, and in the Farmington district (San Juan County), which may be said to be a continuation of the Montezuma district of Colorado. The varieties grown are Ben Davis, Gano, Arkansas Black, Winesap, Jonathan, White Pearmain and Rome Beauty. The apple industry is growing rapidly, especially in the Roswell and Farmington districts. The state bids fair to take third place in the mountain region.

*Utah.*—In 1910, Utah reported 517,000 trees of bearing age and 789,000 not bearing. In 1909 the total apple-production was 350,000 bushels. In the past ten years the state has not shown the growth in apple-production as has Colorado, Idaho, Montana and New Mexico; yet many new orchards are being planted in the Cache Valley (Cache County), Bear Valley (Iron County), Utah Valley (Utah County), and in the Ogden district. These are the leading apple-growing sections of the state. Gano and Jonathan are most widely planted, although Winesap, Rome Beauty and other standard winter varieties are grown in smaller quantities. The orchards are all irrigated.

*Arizona.*—Approximately 1,000 acres were in apple orchards in Arizona in 1910, about one-half being of bearing age. The climate over most of the state is too warm for the apple, and in the mountainous sections of the state where apples may be successfully grown, the areas which can be irrigated are very limited in extent. There is apparently little chance for development in commercial apple growing.

*Nevada.*—With a climate similar to that of Arizona, the apple industry has not flourished in Nevada. Latest census figures credit the state with little more than 1,000 acres of apple orchards. Limited areas located near the Sierra Nevada Mountains in the northwest part of the state are fairly well adapted to apple-culture. The rainfall is light and all orchards are irrigated. A number of the standard winter varieties are grown.

*Wyoming.*—The interest in apple-growing in Wyoming is confined principally to the development of the home orchard. The acreage planted is about equal to that of Arizona or Nevada, with a little more interest now manifest in the development of the industry. The varieties planted are Wealthy, McIntosh and Jonathan.

#### *General practices.*

Generally speaking, this whole region is arid, little being attempted in the way of apple-growing except with irrigation. The atmosphere is dry, and during the summer months there is an exceptionally large amount of sunshine. Especially in the mountain valleys, the days are warm and the nights cool. The entire region is more or less subject to untimely spring frosts. For this reason many of the best fruit sections of the region are found in narrow mountain valleys, protected more or less by cañon breezes, or upon the bench lands of broader valleys, where the air drainage is good. Within this region, however, we find many sections afforded this natural protection where the apple crop seldom fails.

*Soils.*—Within this group of states, apples are grown on a large variety of soils. The great majority of orchards have been planted upon virgin land, and as time goes on, we shall probably learn to consider soil-adaptation a more important factor in apple-growing. From the standpoint of ease of cultivation, ease of irrigation and the maintenance of soil fertility, the medium sandy loams are proving the most satisfactory apple soils.

*Tillage.*—The orchardists of the mountain states have from the beginning been exponents of clean culture. In many sections, however, they are now beginning to feel that this has been overdone, and in the present system of tillage, clean cultivation and cover-crops alternate. In some cases the orchard is well tilled during the early part of the season and seeded to field peas, vetch or other crop in midsummer. Another practice is to seed the orchard to clover, which is turned under after two seasons' growth. The orchard is then cultivated for one or two seasons and again planted to clover. Alfalfa has been used instead of the clover. Providing it is kept away from the trees and within reach of the turning plow, alfalfa is not objectionable in orchard lands free from stones. On rocky land it is difficult to kill the alfalfa out. In this arid region, some such system of tillage must be practised as a means of maintaining soil-fertility.

*Irrigation.*—The irrigation practice of the orchardists of these states is not unlike that of the other western states. Practically all water is applied by the furrow method, running shallow ditches close together in sandy soils and deep ditches farther apart in the heavy soils. The distances between ditches will vary from 2 to 6 or 8 feet. The old orchards receive from two to four applications during the growing season. The plan is to get the fruit up to size early in the season and then promote coloring by maintaining only a moderate moisture supply during the latter part of the summer. In sections where the winters are dry, both the old and young orchards receive one late fall irrigation. This is applied after the first frosts when there is no longer danger of starting new growth. The young orchards are well watered during the early part of the growing season. After midsummer, little water

is applied. Every effort is made to check the growth of the trees early, for when well matured they withstand severe freezing best.

*Pruning.*—The apple-growers of the mountain states are quite unanimous in their choice of the vase-form as the standard to be worked for in training apple trees. While the eastern grower many justly condemn such a system of training on account of limited fruiting area, the objection is without merit in this region where the tendency is for most varieties to overbear. In the first three or four years in the orchard, the young trees are severely headed-in each spring, the object being to get a stocky trunk with the first scaffold limb within 12 or 18 inches of the ground and three or four more spaced along the trunk at intervals of 6 inches. After these first three or four prunings, little heading-in is done until the trees begin to overbear. The trees are then cut back and thinned out sufficiently to induce annual bearing and the production of fruits of desirable sizes with the minimum amount of hand thinning. In the commercial fruit-growing sections, the fruit is systematically thinned. There is little occasion for summer pruning.

*Marketing.*—The bulk of the apple crop of these states is sold in standard apple-boxes, and much of the fruit is wrapped and packed in sizes in tier packs. As a rule, the fruit is marketed through coöperative fruit-growers' associations, some of the oldest and most successful associations in the United States being found in this region. The fruit is generally distributed in all eastern, southern and western markets where extra fancy boxed apples are in demand.

*Diseases and insects.*—The apple-growers of the mountain states are little troubled with fungous diseases. During the summer season the atmosphere is generally dry and the fungi apparently do not thrive. In some of the more humid sections of this region, especially in rainy summers, apple scab becomes a serious menace. It is easily controlled, however, with the lime-sulfur sprays. Over the entire region, pear blight has attacked some of the more susceptible varieties of apples. The planting of Alexander and Transcendent Crab has been discontinued on this account, and in some sections other varieties must be watched carefully and will probably be discarded eventually.

Of the apple orchard insects, the codlin-moth is easily the most important, and over almost the entire region up-to-date methods of control must be employed. Both the green and woolly aphids are ever-present enemies of the apple orchards, the first troubling young orchards especially. The San José scale has not as yet become a troublesome pest in the apple orchards of the greater part of the mountain region. The oyster-shell scale, the bud-moth and the green fruit-worm are of only local importance.

The majority or orchardists of this region are well equipped with modern power spraying machinery, and as a rule are well posted on spraying methods.

O. B. WHIPPLE.

### The apple in Oregon and Washington.

The states of Oregon and Washington are noted for their diversity of fruit conditions. Their soils range from the lightest loam to the heaviest adobe; their rainfall varies from 8 or 9 inches to over 100; their elevations extend from sea-level to the snow line. From the horticulture of each of these states, which is thoroughly described in this Cyclopaedia, the readers can get complete details concerning these special characteristics.

In Oregon apple-culture is largely confined to such valleys as the Rogue River, Umpqua, Willamette, Hood River, Freewater-Milton, and Grande Ronde, with certain developments along the coast, especially in such regions as Coos Bay.

In Washington the development is largely east of the Cascade Range in such inland districts as Wenatchee, Yakima, Walla Walla and Lewiston-Clarkston.

### General considerations.

Apple-culture on the Pacific Coast is characterized by the following:

*Communal development.*—In such valleys, for example, as the Hood River (Fig. 277) or Wenatchee, one finds that apple-growing is almost the sole industry, and large contiguous areas are devoted to apple-production alone. One sees the entire absence of diversity of agriculture in some districts. These orchards may occasionally be very large, although in the more highly developed regions the tendency is for small orchards very intensively developed.

*Intensive tillage.*—There is practically not a fruit-grower to be found on the Pacific Coast who is not a firm believer in tillage. In a few sections, the introduction of shade-crops is supplementing the former intensive tillage, but the almost universal practice is to till very intensively.

*Systematic spraying.*—Each orchard is given frequent sprayings, according to a specified program. There are very few orchards on the Pacific Coast that are not equipped with power sprayers, capable of maintaining 200 pounds of pressure. Pacific Coast apple-growers are thoroughly alive to the value of spraying for pests.

277. Apple orchard in Hood River valley.

*Methodical thinning.*—It would be very hard indeed to find any fruit districts in which the orchardists do not thin regularly. They would no sooner give up thinning than eating. It is thought by a great many growers that thinning pays a larger dividend on the investment than any other orchard practice.

*Skillful packing.*—The Pacific Coast has long been famous for the high-grade packing of its fruit products. Lively effort is made to educate the growers to be skillful fruit-packers, and rigid systems of inspection are maintained in order that the high grade of the pack may not be sacrificed.

*Spirit of coöperation.*—Almost every community is thoroughly organized. The spirit of coöperation has taken a firm hold with the people and its benefits are thoroughly realized. Not only have certain sections organized, but there is every indication at the present time that within the next few years apple interests of the entire Pacific Coast will be consolidated into a central selling agency.

*The personnel of the Pacific Coast fruit-growers* can be characterized by the large number of young men, especially college graduates, who are engaging in apple-culture. In Hood River alone there are in the neighborhood of one hundred and thirty college graduates from all parts of the country engaged in apple-growing and making it a life-work and study. There are also large numbers of retired business and professional men from various parts of the country. Such men, because of their enthusiasm, are anxious to adopt up-to-date methods in order to make very successful fruit-growers. They intend to specialize in making apple-growing a very serious business. It is not an uncom-

VIII. The York Imperial apple.

mon thing to find a man devoting his entire energy to the growing of two varieties of apples.

#### *Orchard management.*

Most of the orchardists practice annual spring plowing. In some of the lighter soils, disking takes the place of plowing, but the present tendency is to plow and harrow down the soil very thoroughly. With the heavy loams the plowing is generally followed by light harrowing, supplemented by the use of the clod-masher, corrugated roller or brillion. After the ground is placed in good condition, frequent cultivations are made. One of the best tools to use in such cases is the Kimball weeder; this stirs the soil and prevents drying or baking of the surface soil. Often as many as eighteen harrowings are given during the summer-time. By the middle of August or at such time as the young trees have made sufficient growth, cultivation ceases, but with the heavier-bearing orchards cultivation is generally continued up to the harvesting. With the lighter soils, such as many of the volcanic ash, after the ground has been plowed in the spring, the tendency is to compact the ground more by the use of subsoil packers or by dragging the ground with floats. Such soils tend to blow out constantly and it is only by these methods that the moisture can be retained in the surface soil.

*Irrigation.*—Irrigation becomes more and more a factor to the Pacific Coast apple-grower east of the Cascade Mountains where the rainfall is less than 15 inches. Irrigation is made to supplement tillage. The water is applied by the furrow or rill system, and as soon as possible after irrigation the ground is thoroughly harrowed and, after becoming smooth, is kept in good shape with smoothing harrows. Irrigation is practised more with trees fifteen years of age and up than with young trees.

The growers are finding out that an abundant supply of moisture either through intensive tillage or irrigation tends to make the trees produce larger crops, makes them annual bearers, increases the individual size of the specimens and tends to make the fruit more elongated and of a livelier, brighter color. In some cases too much moisture is used, resulting in soft, poorly colored fruit of poor shipping qualities.

*Fertilizers.*—At the present time no commercial fertilizers are being used. The growers, however, are taking hold of cover-crops very enthusiastically. Vetch becomes a principal crop,—the forage or Oregon vetch in the region where the climate is mild, and the hairy vetch where the climate is severe. The vetch is generally combined with rye, oats, or wheat, and is drilled in by the latter part of August, about forty pounds of vetch and ten pounds of rye being the common amount to use to the acre. Under normal conditions, from 2 to 3 feet of growth can be realized by early spring.

*Shade-crops.*—In the irrigated sections where the tendency to use shade-crops is becoming common, alfalfa and the clovers are the principal crops grown. There is a great difference in opinion among the growers whether alfalfa is a suitable crop to use as a shade-crop, clovers being more commonly used. Some growers practise growing clover for two years, cutting it and allowing it to mat on the ground; while other growers disk the clover under each year and allow it to reseed itself. The practice of growing shade-crops is yet so new that it will be a number of years before the growers unite on some practice, but a larger percentage of growers are resorting to shade-crops each year.

*Thinning.*—Nearly all varieties of apples are thinned very carefully. The thinning generally begins as soon as the drop is over, in some places before the drop takes place. The apples are thinned at various distances, according to varieties. The red apples are generally thinned one to a spur. With yellow apples, there is a

tendency to leave two specimens on certain spurs but to remove all the fruit from the remaining spurs. The growers think that when this method is followed there is a tendency to maintain the trees as annual bearers. The distances apart vary extremely. Winesaps are thinned from 8 to 10 inches apart, whereas the larger varieties of apples are thinned rather sparingly, as they often have a tendency to overgrow if thinned too vigorously.

*Pruning.*—Most growers practise annual pruning. The trees are started very low, the head being 9 to 18 inches from the ground. Most of the growers resort to what is known as the open, goblet or vase tree. In this tree, most of the branches issue from one point and the trees are kept open constantly by rigorous pruning. The growers think that more light is allowed to play around the fruit by such a system and that a better color is developed. During the first three years, the trees are cut back very rigorously each spring, but as they become older less heading-back is resorted to and more thinning-out is practised. Many of the growers are now leaning more to the modification of the center tree, growing what is known as the modified center tree, the leaders being allowed to grow for a few years and then being suppressed. This system gives a better distribution of the branches and makes a stronger tie, and it also gives a larger fruiting area. Some growers contend that varieties like the Yellow Newtown do better if trained as leaders.

There is much sentiment among the fruit-growers on the Pacific Coast in favor of summer pruning. In their enthusiasm, many of them are overdoing summer pruning. On the stronger loams certain varieties like Yellow Newtown are slow in coming into bearing, but on the lighter loams and higher altitudes come into bearing in three to five years. In such cases summer pruning is not resorted to.

*Pollination.*—Pollination has become a subject to which the Pacific Coast growers are paying a great deal of attention and the orchards are now being planted in oblong blocks of two to six rows of a variety. It is felt that where this is practised, a larger set of fruit is secured, that there is a greater uniformity in the crop and a tendency for increase in size of specimens. Formerly trees were planted in large blocks, but the heavy shedding of fruit has caused the growers to abandon this system and plant so that interpollination can take place.

*Frost-fighting.*—Frost-fighting is resorted to in many of the mountain valleys that are early and subject to damage from frosts. The most common method for controlling is smudging with oil in pots. The last few years many growers have been very successful in saving the crops under adverse conditions. See *Orchard Protection*.

*Spraying.*—Practically every grower has a spray calendar which he follows very carefully. Power outfits are used extensively and high pressure is maintained. In all the older orchards, high platforms are built on the spray outfits so the trees can be thoroughly covered with spray. The principal diseases are the mildew, found more in California and southern Oregon; apple scab; apple tree anthracnose, or black spot. These are about the only diseases that receive much attention. Of the insect pests, the codlin-moth and aphids are the most serious. The codlin-moth is distributed over the entire district with the exception of the coast regions, which are free from this insect pest. The green aphid attacks the young trees injuriously, and for the past two years the brown aphid has been of serious menace to the fruit. In some regions the brown aphid is now doing more damage than the codlin-moth. The scale insects, for the present time, receive very little attention, as they are so easily controlled. Occasionally the red-spider and borers give considerable trouble.

*Packing.*—The apples are all packed in boxes known as the Northwest Standard, 10½ x 11½ x 18 inches.

All the better grades of apples are wrapped in paper, and lithographs are placed on the boxes. The fruit is graded very carefully before packing. The present tendency is to use one size of box and pack the apples by what is known as the diagonal pack.

*Packing-houses.*—Very large and expensive packing-houses are being erected all over the Pacific Coast and enormous storage plants are being built at all the immediate shipping points. In most cases, the packing is very rigorously inspected. Most of the states have laws that require the grower to put on the box his name, the grade of fruit and the number of specimens in the package. Most associations require the packer to stamp his number on the box, so that in the case of any imperfections it can be easily traced.

*Marketing.*—The marketing of the fruit is done largely through associations. By coöperating, the growers have been able to improve constantly their pack and have also tended to distribute the fruit more widely. At the present time, the Pacific Coast is sending fruit to nearly all the leading ports of the world, and the effort is made to get a wider and wider distribution rather than to send it to a few distributing points like Chicago and New York, which was the system formerly followed.

The willingness of the people to organize, and the coöperative system, which is broadcast in the region, is a very important factor in successful apple-culture on the Pacific Coast.

C. I. LEWIS.

### The apple in California.

Although the apple was introduced into southern California by the Mission padres nearly a century before the American occupation, and although the Russians established an apple orchard in northern California more than a quarter of a century before the gold discovery, it was not fully demonstrated until about 1880 that the state can produce an apple of character and quality to entitle the region to standing among

278. A California apple orchard.

the commercial apple regions of the United States. California pioneers were accustomed to concede apple adaptations to Oregon and to claim none for themselves. This was chiefly due to the fact that early plantings were made in the mining districts of the lower foothills and on valley lands adjacent to routes of travel thereto from the port of San Francisco. Climatic conditions in such situations forced too early maturity of winter varieties, which impaired quality and keeping and, as main commercial desirability was vested in long-keeping, California was conceded to lack adaptations for the production of a good apple, and local supplies of the fruit were drawn for three decades from the orchards in western Oregon. Popular judgment was, however, reversed by the notable long-keeping of California apples shown at the New Orleans Fair in 1885, which is explained by the fact that the exhibits were

gathered from family orchards in the coast districts and in the high plateaus and mountain valleys where growing conditions are quite unlike those of the lower foothills and adjacent valleys. The conclusion from this demonstration was that when the right variety is planted in the right place, in California, superior fruit, both for local use and long shipment, may be secured. Since that time, California apples have been successfully sold in considerable quantities in England and on the continent of Europe, on the Atlantic Coast of America, in Australia and in Eastern Asia—as well as throughout the interior states of the Pacific Slope, in Canada and in Alaska. The uprise of a great apple industry in other states of the Pacific Slope has, however, recently excluded the California winter apple from large American areas in which it formerly sold freely, but California still retains in the same areas its market for summer and fall apples because mature fruit can be shipped before the same varieties ripen farther north or at greater elevations. Fig. 278 shows a representative California apple orchard.

### Summer apples.

It is now clear that there are two distinct branches of the apple industry of California, in which, first, effort is concentrated on the production of summer apples in what are known as early districts and, second, fall and winter apples in other districts where slower development is favored by prevalence of lower spring and summer temperatures. In the interior valleys and lower foothills, the forcing heat brings early varieties, like the Astrachans, quickly to notable size, crispness and flavor, and there is an ample demand for such fruit for shipment, providing it is sound and free from pests, some of which, however, are more aggressive than they are in cooler sections. Fall apples are successfully grown in the same districts but they also are profitable in the coast district, as is shown by the behavior of the Gravenstein in the Sebastopol section of Sonoma County where "Gravenstein shows" are annually held in August. Another instance of specialization is found in the commercial importance of the Yellow Bellflower in the Watsonville district, where it enters largely into the "Apple Annual"—a greater exhibition held the first week in October. In these typical fall-apple districts, the winter apples are also important, the Esopus (Spitzenberg) leading these varieties at Sebastopol and the Yellow Newtown at Watsonville. These facts emphasize the importance of certain varieties; for specialization is built upon varieties even more than upon the classes to which they belong.

### Winter apples.

The chief importance does, however, rest with the winter apple in California, in the same way, but perhaps not to such a degree, as in other apple-growing states and countries, and the chief investment and expectation are made upon that basis. Aside from the conditions cited, which make nearly exclusively for the summer and early fall varieties, the state has great capacity for the production of winter apples of the type for which the coast has become so famous during the last few years. Every county in the state has apple trees, but the requirements of a winter apple are fully met by two main divisions of the state, viz.: the smaller valleys close to the coast, in fact, in some cases, the coast flats, where the exposure is directly toward the cooling breezes of the ocean which produce a cool summer—a long, slow-growing season, which develops great beauty and high quality in a winter apple. Similar results are also produced by the climate found at an elevation of about 2,500 to 5,000 feet on the interior plateaus and in the mountain valleys. The coast district has developed a greater commercial apple industry than the mountains, because transportation facilities for shipment are vastly better; but as the state advances, the mountain

districts will be employed in this production much more largely than at present. The greatest apple district of the state now is the Pajaro Valley, including parts of Monterey and Santa Cruz Counties, centering at Watsonville, which shipped about 6,000 carloads of apples in 1912. The county next prominent in apple-growing is Sonoma; Santa Cruz and Sonoma Counties have about one-half of all the trees in the state, while many other counties have good apple orchards in less total acreage; in fact, from San Diego on the south to Siskiyou on the north, localities exist which afford the elevation or the coast exposures that favor the production of good winter apples, and planting is progressing in all these districts.

#### Extent.

The number of apple trees in California in 1913 is about 2,500,000, occupying, as nearly as can be calculated, 30,000 acres of land. The varieties of chief commercial importance, in order of ripening, are: White and Red Astrachan, Gravenstein, Yellow Bellflower, Yellow Newtown, Esopus, White Pearmain, Winesap and Rome Beauty. Many other winter varieties have been planted recently in different districts, but their relative importance cannot be predicted.

E. J. WICKSON.

**APRICOT.** *Rosaceæ*. A tree and fruit somewhat intermediate between the peach and the plum, grown largely in California and in special localities in the East.

The apricot tree is a round-headed grower, with dark, somewhat peach-like bark, and very broad or almost circular leaves. The fruit, which usually ripens in advance of both the peach and plum, is peach-like in shape and color, with a smoother skin, rich yellow flesh and large flat smooth stone. The flesh is commonly less juicy than that of the peach, and, as a rule, perhaps, of higher quality. The apricots are of three species, all probably native of China or Japan. (1) The common apricot of Europe and America is *Prunus Armeniaca*: fr. variable, but smooth at maturity, red or yellow, the sweet and firm flesh free, or very nearly so, from the large, smooth, flat stone: tree with a round, spreading top, and a reddish, cherry-like or peach-like bark: lvs. (Fig. 279, right) ovate or round-ovate, with a short point and sometimes a heart-shaped base, thin and bright green, smooth or very nearly so below, as are the gland-bearing stalks, the margins rather obtusely and mostly finely serrate: fls. pink-white and borne singly, sessile or very nearly so, preceding the lvs. (Fig. 280). The Russian apricot is a hardy but smaller-fruited race of this species. (2) The Japanese apricot, in Japan grown for flowers rather than for fruit, is *Prunus Mume*: fr. small, yellowish or greenish, the flesh rather hard and dry, and adhering tightly to the pitted stone: tree like the common apricot, but with a grayer or greener bark and duller foliage: lvs. grayish green, generally narrower (Fig. 279, left) and long-pointed, more or less hairy along

279. Apricot leaves.  
P. *Mume* on left;  
P. *Armeniaca* on right.

the veins below and on the shorter mostly glandless stalk, thick in texture and prominently netted beneath: fls. fragrant, borne singly or in 2's, and sessile (without stalks); more lately intro. into this country, chiefly under the name of Bungoume plum. (3) The third species is the purple or black apricot, *Prunus dasycarpa*, which is little cult.: fr. globular and somewhat plum-like, with a distinct st., pubescent or fuzzy even at maturity, dull dark purple, the sourish soft flesh clinging to the plum-like fuzzy stone: tree round-headed, with much the habit of the common apricot, with lvs. ovate and more or less tapering at both ends, thin, dull

green, on slender and pubescent, mostly glandless, stalks, finely appressed-serrate and hairy on the veins below: fls. large and plum-like, bluish, solitary or in 2's, on pubescent stalks  $\frac{1}{2}$  in. or more long, and appearing in advance of the leaves. See *Prunus* for related species. The apricot-plum, *Prunus Simoni*, is discussed under *Plum*. The plumcot is a hybrid of plum and apricot, accounted for under *Prunus*.

L. H. B.

**East of the Mississippi** the apricot is not grown commercially to great extent, although it is a popular fruit for the home orchard and garden. As a commercial crop, it does not seem to be increasing in favor. There are two important reasons for this: the loss of the fruit by spring frosts because of the very early season of bloom, and the great liability to curculio attack. Possibly the apricot has not yet been given a thorough test. Its value may be more appreciated and the difficulties of its culture lessened when the fruit has received greater study and attention.

280. Flowers of the apricot.

The apricot is as hardy as the peach and thrives in similar localities and under the same general cultivation and treatment, but demands very strong soil. The ideal land for this fruit seems to be one that is deep and dry, and loamy or gravelly in character. The rolling loamy lands that are well adapted to apples seem to be well suited to the apricot, if the exposure and location are correct. The apricot is particularly impatient of wet feet, and many of the failures are due to retentive subsoils. The kind of soil has an important bearing also on the stock to be used.

Particular attention should be given to the location and exposure of the apricot orchard. In the East the best results are secured if the plantation stands on elevated land near a large body of water, for there the spring frosts are not so serious as elsewhere. Generally a somewhat backward exposure, if it can be had, is desirable, to retard blooming. Apricots will be sure to fail in frosty localities.

The apricot should always be given clean culture. For the first two or three years, some hoed crop may be grown between the rows, but after that the trees should be allowed the entire land, particularly if set less than 20 feet apart. Tillage should be stopped late in summer or early in fall to allow the wood to mature thoroughly. It is best to raise a cover-crop in the latter part of July or in August to hasten this maturity and also to protect the roots and to improve the physical properties of the soil.

The trees are pruned in essentially the same way as plums. The fruit-buds are borne both on spurs (two are shown in Fig. 281) and also on the wood of the last season's growth on either side of the leaf-bud, as shown in the twin and triplet buds above *a* in Fig. 281. Each bud contains a single naked flower (Fig. 280). As the fruit begins to swell, the calyx-ring is forced off over the top (Fig. 282) and the injury from curculio may then be expected. The fruit is often borne so close together as to appear to be in clusters (Fig. 283).

When grown under the best conditions, the apricot may be considered to be nearly or quite as productive as the peach. Like other fruit trees, it bears in alternate years, unless the crops are very heavily thinned. It can never be recommended for general or indiscriminate planting. Only the best fruit-growers can succeed with it. Apricots are to be considered as a dessert or

fancy fruit, and therefore, should be neatly packed in small and tasty packages.

The varieties mostly in demand in the eastern states in order of preference are: Moorpark, Harris, Alexis, Montgamet, Budd, Early Golden, St. Ambroise, Alexander and Peach. The Royal and Superb are grown to some extent. Of the above-mentioned varieties, the

Harris, St. Ambroise, Montgamet, and Early Golden are early as regards season of ripening; the Peach and Moorpark are medium; the Alexander, Alexis and Budd are late. The Alexander, Alexis, Budd and some others belong to the Russian race. Fig. 284 shows a good-shaped apricot.

The apricot is propagated by budding or grafting the desired varieties on the peach or plum stock. On its own root the apricot seems to be less successful, probably because of the peculiar soil-requirements that it demands. The peach seems to give a better union and consequently a better stand, whereas the plum stock gives a tree that is harder, longer lived, and less subject to attacks of borers. Both Myrobalan and Domestica stocks are used, the preference being for the latter.

The most serious enemy of the apricot is the curculio, the same insect that attacks the fruits of plum and peach. This insect seems to have a particular fondness for the apricot, and as the fruit sets very early, the crop may be expected to be destroyed unless the most vigilant means are employed. The foliage of the apricot, as in the case of the peach, is especially sensitive to the arsenical sprays and therefore entomologists have hesitated to recommend paris green and arsenate of lead for the control of the curculio. The work of W. M. Scott and A. L. Quaintance, of the United States Department of Agriculture, has shown, however, that arsenate of lead in combination with self-boiled lime-sulfur is successful in controlling this pest on the peach. It is probable that the mixture will be equally successful in controlling the curculio on the apricot. They recommend the use of two pounds of arsenate of lead combined with fifty gallons of self-

boiled lime-sulfur applied as follows:

First application.—About the time the calyces, or shucks, are shedding from the young fruit.

Second application.—Two or three weeks later, or about one month after the falling of the petals.

Another method of control of this insect is by jarring the trees, in the same way as with plums and peaches, but the work must be even more thoroughly done than with those fruits. The jarring should begin as soon as the blossoms fall, and continue as long as the insects are numerous enough to do serious damage. It will usually be necessary to catch the insects for three to six weeks, two or three times a week, or perhaps even every day. The work must be performed early in the morning, while the curculio is indisposed to fly. The operation consists in knocking the insects from the tree by a quick jar or shake, catching them on a white sheet or in a canvas hopper. The catcher formerly used in western New York was a strong cloth hopper mounted on a wheelbarrow-like frame, and run on two wheels. The hopper converged into a tin box, into which the curculios rolled as they fell on the sheet. One man wheeled the device, by barrow-like handles, under the tree, then dropped the handles and jarred the tree; or

sometimes two men went with a machine one wheeling it and the other jarring the trees. If the work of spraying, as above recommended, is done thoroughly, it will probably not be necessary to use this jarring device in addition; and the device is now going out of use.

The apricot is often trained on walls, where the fruit reaches the highest perfection. Care should be taken that the wall does not face the east or the south, or the early-forced flowers may be caught by frost. An overhanging-cornice will aid greatly in protecting from frost.

C. S. WILSON.†

The apricot in California is one of the leading commercial fruits. It was apparently introduced by the Mission Fathers, for Vancouver found it at the Santa Clara Mission in 1792. However, there is no relation between this early introduction and the expansion that quickly followed the American occupation, because the Mission Fathers had only seedling fruits, while the early American planters, shortly before the gold discovery, introduced the best French and English varieties, and were delighted to find that these sorts, usually given some protection in the Old World, grew with surprising thrift of tree and size of fruit in valley situations in California in the open air. Upon these facts the apricot rose to wide popularity. The acreage has steadily increased during the last fifty years, and with particularly swift rate during the last twenty years, until the number of trees reported in 1899 was about three millions, occupying upwards of forty thousand acres of land. Since then, however, the acreage has not increased, because the crop is irregular on account of frost injuries in some districts. The fruit is sold fresh, canned, dried and in crystallized forms, in all the regions of the United States, in England and on the Continent, where, by reason of its superior size and acceptable manner of curing, it has achieved notable popularity. The year 1905 was the greatest thus far in amount of dried product realized, viz., 36,000,000 pounds. The year 1911 was greatest in amount of canned product, which reached upwards of 758,325 cases, each containing two dozen 2½-pound cans. The shipment of fresh apricots out of California during the summer of 1910 was 290 carloads.

The chief part of the apricot crop of California is grown in the interior valleys. In the low places in these valleys, however, the fruit is liable to be injured and sometimes almost wholly destroyed by spring frosts, although the trees make excellent growth. In foothill situations adjacent to these valleys, there is also serious danger of frost above an elevation of about 1,500 feet above sea-level, and the tree is rarely planted for commercial purposes. In southern California the apricot succeeds both in the coast and interior valleys. But along the coast northward, excepting the very important producing regions of the Alameda and Santa Clara valleys, eastward, and southward from the Bay of San Francisco, the apricot is but little grown, owing to frost troubles. In respect to these, the apricot is somewhat less subject to harm than the almond, but it is less hardy than the peach, and has, therefore, a much narrower range of adaptation. The average date of the blooming of apricot varieties is about two weeks later than that of the almonds. The apricot is adapted to a wide range of soils, because to the rather heavy, moist loams which its own root tolerates, it adds the lighter tastes of the peach root, upon which it is very largely propagated. However, attempts to carry the apricot upon heavier, moister soils by working it upon the plum root have not been very successful, owing to the dwarf-

281. Fruit-buds of the apricot. Borne beside the leaf-bud, as on the peach, and also on spurs.

282. Young apricots shedding the ring.

ing of the tree; and the movement toward the light, dry loams, by working upon the almond root, has failed because the attachment is insecure, and the trees are very liable to be snapped off at the joining, even though they may attain bearing age before the mishap occurs. The apricot root itself is a favorite morsel with rodents, and is for that reason not largely used. The mainstay for the apricot, then, is the peach root, and the soils which this root enjoys in localities sufficiently frost-free are, therefore, to a great extent the measure of the apricot area.

Apricot trees are produced by budding on peach or apricot seedlings during their first summer's growth in the nursery row, from pits planted when the ground is moist and warm, at any time in the preceding winter. When there is a great demand for trees, planting in orchard is sometimes done with dormant buds, but ordinarily the trees are allowed to make one summer's growth in the nursery. The trees branch during the first year's growth from the bud, and usually come to the planter with a good choice of low-starting branches, from which to shape the low-headed tree which is universally preferred. The method of securing such a tree is identical with that already described for the almond, but the treatment of the tree after reaching bearing age, in its third year, is very different from the after-treatment of the almond. The apricot is a rampant grower and most profuse bearer. Unless kept continually in check it will quickly rush out of reach, and will destroy its low shoots and spurs by the dense shade of its thick, beautiful foliage. There is continually necessary, then, a certain degree of thinning of the surplus shoots and shortening of the new growth, to continue the system of low branching, to relieve the tree from an excess of bearing wood, and to avoid small fruit and exhaustion of the tree, resulting in alternate years of bearing. In the coast regions, where the tree makes moderate wood-growth, it can be kept in good form and bearing by regular winter pruning. In warmer regions, where the tendency is to exuberant wood-growth, the main pruning is done in the summer, immediately after the fruit is gathered. This has a tendency to check wood-growth and promote fruit-bearing, and where the main cutting is done in the summer, winter pruning is reduced to thinning out shoots, to prevent the tree from becoming too dense and to lessen the work of hand-thinning of the fruit later on. In addition, however, to the most intelligent pruning, much fruit must be removed by hand when there is a heavy set of it, in order to bring the fruit to a size satisfactory to shippers or canners, and to reach the highest grades, if drying is practised. California apricot orchards are all grown with clean tillage, for the main purpose of moisture conservation. In regions of good rainfall and sufficiently retentive loams no irrigation is required; good tillage will suffice for the production of large fruit and perfection of fruit-buds for the following year. As the trees are becoming older and bearing larger crops the demand for moisture increases, and the use of irrigation water is growing. In most places, however, one irrigation is sufficient, and that is given after fruit-gathering, to carry the tree through the last half of its season's work. In the regularly irrigated regions of the state, water is periodically applied through the growing season, in such amount and at such intervals as the local climate and soils require.

Although probably all the good varieties of the apricot in the world have been introduced into California in the last half-century, and scores of selected seedlings of local origin have been widely tested, the varieties that have survived the tests and are now widely grown

are comparatively few in number. Most of the rejected varieties met this fate because of shy bearing, and those which now constitute the bulk of the crop are very regular and full bearers, under rational treatment. A local seedling, the Pringle, was for many years chiefly grown for the earliest ripening, but this has recently been largely superseded by another local seedling, the New-castle, which is of superior size and about as early. The European varieties, Large Early and Early Golden, are fine in a few localities where they bear well, and do better in southern California than elsewhere. The universal favorite is the Royal; probably three-fourths of all the trees in the state are of this variety, though recently the area of the Blenheim has been increasing largely. The Hemskirk stands next to the Blenheim in popu-

283. A characteristic branch of apricot.  
( $\times \frac{1}{2}$ )

larity. The Peach is largely grown in the Sacramento Valley. The best apricot grown in California is the Moorpark; in size and lusciousness, when well ripened, it heads the list. It is, however, rather shy in bearing, and is forsaken for this fault in most regions. It shows the best behavior in the Santa Clara Valley, and is there retained, in spite of frequent lapses, because of the high prices which it commands at the canneries. About a dozen other varieties are carried in small number by the nurserymen to meet limited local demands.

Apricots for canning and drying are graded according to size: Extra, not less than  $2\frac{1}{4}$  inches in diameter; No. 1, 2 inches; No. 2,  $1\frac{1}{2}$  inches; No. 3, 1 inch. The first three grades must be sound, clean and free from blemish, and No. 3 must be of good merchantable quality. The shippers and canners require well-colored but only firm-ripe fruit, because both the long rail transportation and the canning process require it; soft-ripe fruit will neither can nor carry. For drying, riper fruit is used, and yet over-ripeness has to be guarded against to avoid too dark color. For canning, the fruit must be carefully hand-picked; for drying, much is shaken from the trees. The drying process consists in cutting

the fruit in halves longitudinally, dropping out the pits and placing the halves, cavity uppermost, upon light wooden trays. Breaking or tearing the fruit open will not do; it must show clean-cut edges. When the trays are covered they are placed in a tight compartment, usually called a "sulfur box," though it may be of considerable size, and the fruit is exposed to the fumes of slowly burning sulfur, to ensure its drying to the light golden color which is most acceptable to the trade. The production of the right color is the end in view, and different dryers regulate the amount of sulfur and the length of exposure according to the condition of their fruit and their judgment of what it needs. The exposure varies from half an hour to two or three hours, according to circumstances. After sulfuring, the trays are taken to open ground, and the fruit is cured in the sun. Only a very small fraction of the California product of evaporated apricots is cured in an evaporator. It requires about six pounds of fresh apricots to make one pound of cured fruit.

284. Good apricot fruits, one-half natural size.

A moderate estimate of the yield of apricots might be placed at seven and one-half tons to the acre; extreme yields are far away from this both ways.

The apricot is, as a rule, a very healthy tree in California. It is, however, subject to injury by scale insects of the lecanium group in some parts of the state. During recent years there has been increasing injury by a shot-hole fungus, which perforates the leaves and makes ugly pustules upon the fruit. Such fruit is unfit for canning except the fruit be peeled, which is little done as yet. It also makes low-grade dried product. This fungus can be repressed by fungicides of the copper class.

EDWARD J. WICKSON.

**AQUARIUM.** The aquarium as here understood is a glass tank for live fish, plants, and the like, for the dwelling-house or other suitable place.

The aquarium should be in a place where it may receive light, but direct sunlight is not necessary; and to keep an aquarium in a healthy condition, living plants in the water are absolutely necessary and plants will not thrive in dark rooms; neither will fish retain their bright coloring. The square or rectangular aquarium with open top affords a large breathing-space or air for the fish—which is another requisite, and the fish will be healthier and live longer than in a glass globe with small neck and orifice. Another and very important factor in the aquarium is sand and small pebbles. These should be washed clean of all soil before placing in the aquarium. About 2 inches over the bottom is sufficient. The plants should be planted before filling the aquarium with water. Figs. 285–287 show useful window aquaria.

An aquarium, to be in a healthy condition, should contain living plants—oxygenators—which are as necessary as food, as fish must have good air. The aquarium must be kept clean. The sediment should be removed from the bottom with a dip tube twice a week, and the inner side of the glass cleaned with a wiper once a week. Encourage the growth of the plants at all seasons; admit plenty of light, but no direct sunshine. There should also be a few tadpoles and snails in the aquarium. These are very essential, as they are scavengers, and devour the confervoid growth that frequently accumulates on the plants. In fall, give a thorough cleaning and rearrangement of the aquarium, so that all are in the best condition possible before winter sets in. In March it should be carefully looked over, and undesirable plants removed or transplanted. Additions may be made or any change if necessary.

Following are some of the best plants to place in the aquarium, all of which can be easily and cheaply procured from dealers who make a specialty of aquatics: *Cabomba caroliniana* (commonly called Washington-grass or fish-grass) is one of the very best oxygenators and a most desirable plant for the aquarium and can usually be had in quantity at any season, except late in winter. It is usually sold in bunches, but after winter sets in, bunches of cabomba will not remain long in a healthy condition in the aquarium without care and attention. Plants to be of benefit in the aquarium must be living, and before these bunches of grass can emit roots and be self-sustaining, the fish too often nibble and disturb them to such a degree that, instead of being serviceable to the aquarium, they are a positive injury. *Elodea*, or *Anacharis* (water pest): there are two forms of this useful plant. *E. canadensis* is a very rapid grower and may be found in ponds in dense masses. When once established, it is a pest and hard to eradicate; but being of stem growth, it is not so readily grown in the aquarium. The giant form is a very desirable and valuable plant and can be used to good advantage, making a very interesting as well as a valuable plant in the aquarium. *Myriophyllum spicatum* somewhat resembles the cabomba, but is of a darker color and stronger in growth and texture. It is a hardy plant and will withstand the winters in the neighborhood of Philadelphia. When cabomba is unattainable, this may be had in good condition. It is also an excellent plant to use for fish spawn during the breeding season. This must not be confused with the *Myriophyllum proserpinacoides*, commonly called parrot's feather, as the latter is useless as an aquarium plant.

*Sagittaria natans* is a very pretty strap-leaf variety of sagittaria and useful for a small aquarium. But *S. sinensis*, the giant form, is the best of all sagittarias for the aquarium, and is indispensable. When planted in the aquarium and allowed to get well rooted before the fish are introduced, it can be relied upon to maintain the aquarium

285. A museum-jar aquarium.

286. A rectangular glass aquarium.

in a healthy condition for several months. *Vallisneria spiralis* (eel-grass, tape-grass, wild celery) is a native plant inhabiting streams and rivers, and often used in the aquarium. Its long, narrow, strap-like blades or leaves are more flexible than the sagittaria and the tips float on the surface of the water. They are light green in color and of softer texture. It is a difficult plant to carry over winter, its natural propensity being to die down in winter, just the season when it is wanted in evidence in the aquarium. *Ludwigia Muletti* is one of

287. Permanent aquarium made of wood and glass.

the most conspicuous, ornamental and useful plants for the aquarium and is always in great demand. It is much larger and a stronger grower than *L. palustris* of the middle and northern states. It is a native of the southern states, whence come our supplies in winter in small quantities and for high prices, the plants very unsatisfactory at best. The difficulty is that plants, or rather sprays, plucked from growing plants and shipped North, receive a violent check in the change of temperature and the closely confined condition of the packing-case. The result often is that the plants or sprays lose a great part of their foliage, and when afterward subjected to cold running water are completely ruined. The only safe way is to secure stock during the summer or early fall, getting plants established in pots before preparing the aquarium for winter. In this condition, the plants will hold their own and winter over; but to attempt to grow southern stock in winter in our northern states is futile. There are a few other submerged plants that might be used, but the above-mentioned are the best and the best oxygenators for large or small aquariums. Floating plants should be used sparingly in the aquarium, an open, clean surface being most desirable and even necessary for air. Moreover, the majority of the floating plants are suitable only for summer culture. Another reason why surface or floating plants do not succeed in a house aquarium is that the water is deficient of plant-food suitable for such plants. Plants that die in an aquarium would, if transferred to a tub containing a quantity of soil, as well as water, make rapid and healthy growth. *Limncharis Humboldtii* (water poppy) is a plant often used in the aquarium. It is necessary to plant this in the sand in the same manner as other aquatic plants, although the leaves are floating, similar to the leaves of a pond-lily. *Eichhornia crassipes major* (water hyacinth) is a very desirable plant for catching the fish spawn, but under ordinary conditions lasts but a few days in the aquarium. Miniature plants of these are very pretty, and fish are very fond of nibbling at the roots to the detriment of the plants. These, with many other plants, are best adapted for the summer aquaria where they can enjoy the benefit of sunlight and open air.

Numerous free-floating plants are adapted to the aquarium, but too many must not be in evidence, or the fish may become suffocated. The azollas are very pretty, and the fish

will occasionally eat the plants. The salvinia is another small plant often seen in the aquarium, but under favorable conditions it grows very rapidly, and forms a complete mat, which must be avoided. The European and American frog's-bits (*Lemnium Spongia*, *Hydrocharis Morsus-ranae*) are very attractive plants, their long, silky roots reaching down in the water.

In summer the plants and fish should be placed out-of-doors in a fountain basin, pool, or a tub sunken in the ground in a partially shaded place; and a fresh aquarium should be stocked in the fall.

Aquariums are rapidly increasing in popularity for home use, and are of great service in nature-study. A permanent aquarium need not be an expensive affair. The rectangular ones are best if large fishes are to be kept, but they are not essential. A simple home-made aquarium of glass and wood (Fig. 287) is described in Jackman's "Nature Study," as follows (the dimensions being slightly altered): "Use an inch board  $11\frac{1}{2}$  inches wide and 12 inches long for the bottom, and two boards of the same thickness and length,  $10\frac{3}{4}$  inches high, for the ends. Three-eighths of an inch from the edge on either side, with a saw, make a groove  $\frac{1}{4}$  inch deep and wide enough to receive loosely double-strength glass. Groove the end boards and fasten them to the bottom with screws, so that the grooves will exactly match. Partially fill the grooves with soft putty, or, better, aquarium cement, and press into each side a pane of glass. By making the bottom board  $11\frac{1}{2}$  inches long, an ordinary 10 x 12 window pane will be the proper size. When the glass is pressed to the bottom of the groove, draw the two ends in at the top until the glass is held firmly and then fasten them in place by narrow strips of wood, one on each side of the tank, placed on top of the glass and screwed to the end pieces. These strips also protect the hands from injury while working with the specimens in the aquarium. Before filling with water, the inner surface of the bottom and ends should be well rubbed with oil or paraffin and the grooves inside the glass well packed with putty." After the box is made it would be well to let it stand in water for a day or two. The wooden sides will swell and tighten the joints, and leakage will be less probable.

WILLIAM TRICKER.

288. Working drawings for making box shown in Fig. 287.

**AQUATICS.** A term applied to plants suited to cultivation only in water, particularly to those grown in ponds and tanks.

North America is the most highly favored country in the world for the cultivation of aquatic plants. Collections can easily be made to furnish a display of flowers from April to October in the open without artificial heat. There are numerous aquatic plants other than nymphaeas, nelumbiums and victorias. Some very desirable plants are *Acorus japonica variegata* (variegated sweet flag), *Aponogeton distachyus* (Cape pond-

289. Lawn pond of aquatics, with mason-work margin.

weed, or water hawthorn), *Caltha palustris* and *C. palustris* fr. pl. (marsh marigolds), *Cyperus Papyrus* (Egyptian paper plant), *limnanthemum* in variety. Some of the bog or marsh plants may be used in margins, as many varieties of sagittaria, not omitting the common cat-tail, *Typha latifolia*, the hibiscus of mammoth proportion, and the beautiful new hybrids with gorgeous flowers of all shades from pink to scarlet and crimson. See *Bog-gardening*. Figs. 289 and 290 show formal and informal lawn ponds.

**Soil.**—All aquatics require a rich soil, and this without limit, a depth of water from 1 to 3 feet, and ample space to spread their succulent leaves. In a natural pond, in which there is an accumulation of humus overlying a clayey subsoil, nothing more is wanted, but on a sandy or gravelly bottom it is necessary to place a layer of rich earth 12 to 18 inches deep. In artificial ponds, built of masonry (Fig. 289), a layer of rich soil is necessary if the things are to be planted out, as is best for nelumbiums. The soil best suited for aquatics is a turfy loam, inclining to heavy, and thoroughly rotted cow-manure, two parts of the former to one of the latter, and, when possible, it should be composted some time before using, and turned over two or three times to thoroughly incorporate the manure. When cow-manure can not be obtained, other thoroughly rotted manure may be used. The next best fertilizer is pulverized sheep-manure, but this, being less bulky and stronger in proportion, should not be used so freely as other manures; one part sheep-manure to nine of soil is sufficient. Chemical manures, ground bone, horn shavings, and the like should not be used unless in extreme cases, and then very cautiously. Tankage may be used to good advantage. It contains dried blood, and ground bone. It is very desirable for permanent beds or soils that may continue two or more seasons without renewing. The bone is not readily dissolved and has a lasting quality. Blood, being soluble, has immediate effect and is a valuable fertilizer, if used sparingly.

**Depth of water.**—In natural ponds, water-lilies are found growing in water from a few inches to 4 and 6 feet deep, but in artificial ponds a depth of 12 to 18 inches will be found sufficient for most nymphaeas, and 18 to 24 inches is a good depth for victorias. In constructing an artificial pond, a depth of 2 to 2½ feet is ample. Water to the depth of 12 inches above the crowns of the plants is sufficient, and a box containing the soil may be 12 inches deep. Thus a pond 2 feet in depth is deep enough, and will allow a man, with hip

boots on, to walk between the plants with ease. For a small pond, less than 12 feet over, a plank laid across will suffice for all operations.

**Protection.**—Where severe frosts are prevalent in winter, and ice 12 to 18 inches in thickness is found, there will be danger of the roots freezing. In such cases, an additional depth of 6 inches will be a great advantage, and a protection of bracken, salt hay, green manure, leaves, or any other non-conducting materials should be used to protect the masonry, in severe weather, against expansion and breakage. To protect tubs, small pools or ponds, cover with boards and pile on dry leaves to the depth of 8 or 12 inches, then salt hay or fresh stable-manure to keep the leaves from blowing away. This is one of the best means of protection against freezing. The general use of concrete work instead of brick and stone is to be commended. Reinforcement makes the walls frost-proof and water-proof.

**Planting.**—All hardy nymphaeas may be planted any time between the 1st of April and the 1st of September. Those planted early, other things being equal, will give good results the same season, while those planted late will get well established before winter, and will be in excellent condition to start at nature's summons early the following spring. The hardy nymphaeas differ considerably as to rootstocks. Those of the native species are long and of a spongy, soft texture, and rambling in growth, while the European species have a much larger and very firm rootstock, and grow more compact. In planting, all that is necessary is to press the rootstock firmly into the soil, and if there is any danger of the root rising to the surface, place a brick or any weight upon it, to keep it in position until anchored by its own roots. Tender nymphaeas should not be planted until the latter end of May or beginning of June, according to location. They should not be planted out before coleus, alternanthera, and other tender bedding plants. They require to be started indoors, and will be grown in pots, which are much handier to plant than roots of the hardy varieties, and can be planted under the water with ease and facility. Nelumbiums should not be planted until about the 1st of May. Southward the season is earlier. The existing conditions should be such that tubers shall start at once into active growth.

290. A lawn pond.

They should be already "started" before setting out. The tubers should be laid horizontally in a slightly excavated trench and covered with 2 or 3 inches of soil, using a weight, if necessary, to keep the tubers in position. Plants established in pots or pans are very convenient for planting, and may be purchased when tubers can no longer be procured, and can be planted a month later in the season with good results.

The *Victoria regia* has always been an aristocrat among water-lilies, and few cultivators could indulge in such a horticultural luxury. To grow it satisfactorily, a large surface space with a greater depth of water is necessary than for other aquatics, and a higher temperature is needed at the early stages. It can be cultivated in the open air, but artificial heat must usually be applied and protection afforded, so as to maintain a temperature of 85° F. In 1898 the introducer of *V. Trickeri* brought the Victoria within easy reach and culture of all lovers of aquatic plants. *V. Trickeri* is entirely distinct from other known varieties and can be grown in the open alongside of *Nymphaea zanzibariensis* and *N. devoniensis*, and under precisely the same conditions. When planted out about the middle of June, the plants grow rapidly, and will develop their gigantic leafage and magnificent flowers in August, and continue to do so until destroyed by frost. *V. Trickeri* is none other than *V. Cruziana*, which was never introduced into cultivation until 1898. All that existed outside of its native haunts, on the Parana River, South America, was an herbarium specimen of part of a leaf. It is now generally and extensively grown throughout the United States and in Europe where aquatics are cultivated.

**Enemies.**—Aquatics, like other plants, have their enemies in the way of insect pests, although in a less degree than most plants. Aphides are sometimes troublesome, or at least very unsightly. These, however, have their enemies, especially the coccinella (lady-bird), insectivorous birds, and so on. When these do not keep them down, a weak application of kerosene emulsion will make a clearance. Another method of getting rid of these pests, especially in a small artificial pond, where an overflow is (or should be) provided, is to take the hose with a spray, using a little force, and drive the insects off the plants, and, as they readily float on the water, the action with the hose will drive them out at the overflow pipe. Recently an insect pest that has its home in Florida has migrated northward, causing some annoyance. The larva of the moth *Hydrocampa proprialis* eats the leaf, and also cuts out pieces of the same, which it uses for protection, thereby greatly disfiguring the plant, and at the same time making it difficult to get at the enemy. The best remedy for this and the nelumbium moth, which is very much like it, is a lamp trap. Any ordinary lamp placed near the plants at night, and standing in a shallow vessel containing kerosene, will attract the insects, which, on striking the lamp, fall into the kerosene and are no further trouble. For other insects, such as leaf-miners and those which eat the leaves of plants, the best remedy is arsenate of lead. Muskrats are more or less troublesome, especially where nelumbiums are grown. They will eat the tubers in winter and early spring, and will make sad havoc with banks. They will also eat the roots of some nymphaeas. The best remedy for these is the steel trap. A sporadic disease has also made its appearance. The leaves are affected with spots, which, under a damp, warm atmosphere, spread rapidly. Such climatic conditions, followed by bright sunshine, cause the affected leaves to shrivel up. This greatly weakens and checks the plants. This disease yields readily to a weak solution of bordeaux mixture. The same remedy is also very valuable in ridding the pond of all confervoid growth.

*Tub culture* should be resorted to only from lack of space, or when no other method can be adopted (Fig. 291). For this system of culture, nymphaeas should be

chosen that are moderate growers, yet free-flowering, and other miscellaneous aquatic plants. The tubs should hold from 4 to 12 cubic feet of soil for nymphaeas, according to the variety, some being moderate growers, others vigorous and robust. The tubs may remain above ground or sunken. If sunken during the warm weather, the roots are kept cooler, and this is desirable, especially if hardy kinds are grown. A great improvement over tubs is a concrete pool 4 or 5 feet in diameter made in the shape of a tub, and 2 feet deep. A circular form 4 or more feet in diameter should be made and the ground then excavated 8 inches larger than the form. This will allow a wall of concrete 4 inches thick. Wire netting should be used for reinforcing, arranged so as to be in the middle of the wall. Use a mixture of sand,

291. Tub of water-lilies.

gravel or cinders in the following proportion: two bags of Portland cement, three wheelbarrows of sand, five wheelbarrows of gravel or finely broken stone or cinders and lime equal to one-fourth of cement. This must be thoroughly mixed before using. After the second day, remove the form and lay the bottom with the same material 4 to 6 inches thick. This will make a strong, durable, water-tight pool and at a very moderate cost.

WILLIAM TRICKER.

[The standard book on the American culture of aquatics is "The Water Garden," by Wm. Tricker, N. Y., 1897, pp. 120, to which the reader is referred for extensive cultural directions and for lists of aquatic plants. For botanical descriptions of the various kinds of aquatics, with brief, special cultural directions, the reader may consult the articles in this Cyclopaedia, under the various genera, as *Nelumbium*, *Nymphaea*, and *Victoria*.—L. H. B.]

**AQUILEGIA** (from *aquilegus*, water-drawer, not from *aquila*, eagle). *Ranunculaceae*. COLUMBINE. Hardy perennial herbs of the northern hemisphere; grown for their profusion of showy flowers in early summer, and the delicate foliage later on in the year. See page 3565.

Mostly with paniculate branches, terminated by showy fls., and 1-3 ternately-compound lvs., commonly glaucous: the lfts. roundish and obtusely lobed: fls. large, showy, usually in spring or early summer; sepals 5, regular, petaloid; petals concave, produced backward between the sepals, forming a hollow spur; stamens numerous: fr. of about 5 many-seeded follicles.—About 30 distinct species. J. G. Baker, A Synopsis of the Aquilegia, in G.C. II. 10:19, 76, 111, 203 (1878).

The columbines are among the most beautiful and popular of all hardy plants. The tall and strong-growing

species can be used to advantage in half-shady positions. The attractive forms and rich variations in hue of aquilegias come out well when associated with hemerocallis, Siberian irises, thalictrums, polygonatum, *Spiraea Filipendula* and wild ferns. In the North, a similar effect is produced by grouping columbines together with white and blue *Lupinus polyphyllus*, *Campanula persicifolia*, *Iris germanica* and *I. pallida* var. *dalmatica*, Iceland poppies and trollius. For rockeries, the low-growing early alpine species, such as *A. alpina*, *A. Stuartii* and *A. flabellata* are well adapted. Throughout the middle and northern states, columbines need winter protection, dry leaves being preferable for covering.

Seeds sown in pans, in coldframes in March, or open air in April, occasionally bloom the first season, but generally the second. The different species should be some distance apart, if possible, if pure seed is desired, as the most diverse species hybridize directly. They may be propagated by division of the roots in late fall, winter or early spring, but the better way is by seeds. Absolutely pure seed is hard to obtain except from the plants in the wild state; and some of the mixed forms are quite inferior to the true species from which they have come. *A. cærulea*, *A. glandulosa*, and *A. vulgaris* are likely to flower only two or three years, and should be treated as biennials; but *A. vulgaris* may be kept active for a longer period by transplanting.

A light sandy soil, moist, with good drainage, sheltered, but exposed to sun, is what aquilegias prefer. Some of the stronger species, when of nearly full flowering size, may be transplanted into heavier garden soil, even heavy clay, and made to succeed; but for the rearing of young seedlings, a light, sandy loam is essential. The seed of most columbines is rather slow in germinating, and it is necessary to keep the soil moist on top of the ground until the young plants are up. A coldframe, with medium heavy cotton covering, is a good place to grow the plants. The cotton retains sufficient moisture to keep the soil moist on top, and still admits sufficient circulation of air to prevent damping-off of the young seedlings. When large enough, the seedlings may be pricked out into another frame for a time, or, by shading for a few days until they get a start, they may be set into the permanent border, or wherever they are to be placed. (F. H. Horsford.)

A. *Sepals not more than 1/2 or 3/4 in. long: expanded fls. 1 or 1 1/2 in. diam.*

B. *Limb of petal shorter than the sepal.*

1. *Jonesii*, Parry. True st. very short or almost wanting, soft-pubescent: tufted root-lvs. 1-2 in. high from the stout, ascending branches of the rootstock, biternately divided; partial-petioles very short or none; lfts. very crowded: fls. blue; sepals oblong-obtuse, equaling the spurs, and twice the length of the petal-limbs and head of stamens: foliicles glabrous, large, nearly 1 in. long; styles half as long; peduncles lengthening to about 3 in. in fr. July. Wyoming and Montana. G.F. 9:365.

2. *oxysépala*, Traut. & Mey. Plant 2 1/2 ft., slightly pubescent above: radical lvs. long-petioled, secondary divisions sessile: sepals blue, ovate-lanceolate, much exceeding in length the petal-limbs, which are 6 lines long, white, rounded-truncate; stamens not protruding beyond the petal-limb; spur knobbed, bent inward, shorter than petal-limb: foliicles pubescent, with styles their own length. June. Siberia.—Said to be one of the first to bloom, and one of the most attractive in the list. It is one of the most dwarfed; fls. large blue, yellow and white; it comes so much before the others that its pistils, as a rule, all fertilize before any of the other species come into flower." Only recently intro. to cult.

3. *lactiflora*, Kar. & Kir. St. 1 1/2 ft. high, glabrous

292 *Aquilegia canadensis*.

root-lvs. 1-2 in. long; lfts. sessile or the end one shortly stalked, lobes rather narrow and deep; lower st.-lvs. petioled, biternate: sepals oblong, obtuse, ascending, greenish, equaling the broad, greenish petal-limb, but not reaching the head of stamens; spur straight, slender, 1/2 in. long, not knobbed: pubescent foliicles as short as their styles. Summer. E. Siberia.—Not so much used as the following variety:

Var. *atropurpurea*, Vilm. (*A. atropurpurea*, Willd.). Limbs of the petals deep blue or lilac-purple, and the sepals and spur somewhat tinged with the same hue. B.R. 922.

5. *canadensis*, Linn. COMMON COLUMBINE of Amer Figs. 292, 293. Height 1-2 ft.: primary divisions of petioles of root-lvs. 1-2 in., having 3 divisions; 2 or 3 of the st.-lvs. petioled, biternate: fls. several to a st.; sepals yellowish or tinted on the back with red, about 1/2 in. long, not reflexing; limb of petals a little shorter, yellowish, truncate; spur 3/4 in. long, nearly straight, knobbed at the end, bright red throughout; stamens much protruding: foliicles 3/4 in. long, with styles half as long. May-July. Stony banks, east of Rocky Mountains. Introduced 1890. B.M. 246. L.B.C. 8: 888. Mn. 5:21. R.H. 1896, p. 109. F.W. 1878:33.—There are some beautiful hybrids of this and the blue

in the lower part: partial-petioles of root-lvs. 1 1/2-2 in. long; lfts. sessile or short-stalked, 1 in. long, many lobes reaching half way down; st.-lvs. petioled and compound: fls. about 3 to a st.; sepals nearly white or tinged with blue, over 1/2 in. long, narrow; petal-limb half as long as sepal; spur 1/2 in., slender, nearly straight, not knobbed at tip; stamens equal in length to the limb. June. Altai Mts., Siberia.—A desirable species, but not much planted.

BB. *Limb of petal about equal to sepal.*

4. *viridiflora*, Pallas. St. 1-1 1/2 ft. high, finely pubescent throughout, several-fld.: the partial-petioles of

species. Var. *nana*, Hort. Plant 1 ft. high or less: fls. like the type.

Var. *flavescens*, Hook. A pale-ld. yellow-fl. variety. Very pretty. Intro. 1889. This has often been called *A. flavescens*, Wats.; *A. cærulea* var. *flavescens*, Lawson; *A. flaviflora*, Tenney; *A. canadensis* var. *flaviflora*, Brit. B.M. 6552 B.

293. Radical leaves of *Aquilegia canadensis*.

$\frac{3}{4}$  in. long, style half as long. Early. Japan.—Brought from St. Petersburg, 1892.

AA. Sepals about 1 in. long: expanded fl. about 2 in. diam.

B. Spurs shorter than the petal-limb, and incurved.

7. *flabellata*, Sieb. & Zucc. St. 1–1½ ft., few-fl.: partial-petioles of root-lvs. 1 in. or more, lfts. nearly sessile; st.-lvs. large and petioled: fls. bright lilac, or pale purple or white; sepals 1 in. long, obtuse; limb of petal half as long, often white in the lilac-fl. form; spur shorter than the limb, slender toward the end, much incurved; stamens not protruding beyond the petal-limbs: follicles glabrous. Summer. Japan. R.H. 1896, p. 109. Var. *nana-álba*, Hort. (var. *flöre-plëno*, Hort.). Fls. pure white: plant dwarfish. R.B. 15:157. B.M. 8354 (var. *nivea*).

BB. Spurs at least as long as petal-limb.

c. Stamens short, not much protruding.

8. *leptoceras*, Fisch. & Mey. St. several-fl., about 1 ft. high: partial-petioles of root-lvs. over 1 in., lfts. sessile; st.-lvs. petioled biternate: fls. violet, with the tips of the sepals greenish, and tips of the short petal-limb yellow; spur slender, slightly curved,  $\frac{1}{2}$  in. long, not knobbed; stamens protruding a little beyond the limbs of petals: follicles slender, glabrous, nearly 1 in. long. Summer. E. Siberia. B.R. 33:64. F.S. 3:296.—Little used in Amer.

9. *vulgaris*, Linn. (*A. stellata*, Hort. *A. atrata*, Koch). COMMON COLUMBINE of Eu. Sts. 1½–2 ft. high, many-fl., finely pubescent throughout: root-lvs. with 3 partial-petioles 1½–2 in. long, secondary branches certain, ultimate lf.-lobes shallow and roundish, texture firm; lower st.-lvs. petioled and biternate: fls. violet, furnished with a claw, acute, 1 in. long, half as wide; petal-limb  $\frac{3}{4}$  in. long, equaling the head of stamens; spur about same length, stout, much incurved, knobbed: follicles densely pubescent, 1 in. long, style half as long. Summer. Eu., Siberia, and naturalized in Amer. Gn. 12, p. 288; 70, p. 16 (as *A. sellata*). G.W. 3, p. 229. Var. *flöre-plëno*, Hort. Fls. much doubled, ranging from pure white to deep blue. Here belong

many horticultural varieties with personal names. Var. *Vervæneana*, Hort. (var. *foliis-aureis*, Hort. Var. *atroviolacea*, Hort.). Lvs. with yellow variegated lines.

Var. *nivea*, Baumg. (var. *álba*, Hort.). MUNSTEAD'S WHITE COLUMBINE. Often 2–3 ft. high: a great profusion of large, pure white fls. for several weeks in early spring. Var. *nivea grandiflora*, Hort., is much like this.

Var. *olympica*, Baker (*A. olympica*, Boiss. *A. Wittmanniana*, Hort. *A. blanda*, Lem.). A fine variety, with several large fls.; sepals light lilac or bright purple, 1 in. or more in length; petal-limb white. I.H. 4:146. R.H. 1896, p. 108.

Var. *hybrida*, Sims. Much like the last variety, but with stout, lilac-purple spurs as long as the sepals, only slightly incurved.—Probably a hybrid of *A. vulgaris* and *A. canadensis*. B.M. 1221.

10. *sibirica*, Lam. (*A. bicolor*, Ehrh. *A. Garnieriana*, Sweet. *A. speciosa*, DC.). St. 1½–2 ft. high, many-fl.; often nearly glabrous throughout: partial-petioles of root-lvs. 1–2 in., sometimes showing 3 distinct branches; terminal lfts. 1 in. or more broad, lobes rather shallow and rounded; lower st.-lvs. petioled and biternate: fls. pale or bright lilac-blue; oblong sepals fully 1 in. long, spreading or reflexed a little; petal-limb half as long, equaling the head of stamens, and often white; spur rather stout,  $\frac{1}{2}$  in. or more, very much incurved, or even coiled: follicles glabrous, 1 in. long, style  $\frac{1}{2}$  in. Summer. E. Siberia. S.B.F.G. II. 1:90. Var. *flöre-plëno*, Hort. (*A. bicolor* var. *flöre-plëno*, Hort.). Fls. much doubled by the multiplication of both the limbs and the spurs.

Var. *spectabilis*, Baker (*A. spectabilis*, Lem.). A large, bright lilac-fl. var.; petal-limbs tipped yellow. Amurland. I.H. 11:403.

cc. Stamens long, protruding far beyond the petal-limb.

11. *formosa*, Tesch. (*A. canadensis* var. *formosa*, Wats.). Habit as in *A. canadensis*: root-lvs. and st.-lvs. like that species, but fls. brick-red and yellow, or wholly yellow, and sepals larger, quite twice as long as petal-limb; spurs more spreading, somewhat more slender, and often shorter. May–Aug. Sitka to Calif., and east to the Rockies. Intro. 1881. B.M. 6552. F.S. 8:795. Gt. 32:372. R.H. 1896, p. 108. G.C. 1854:836.

Var. *hybrida*, Hort. (*A. californica* var. *hybrida*, Hort. *A. superba*, Hort.). Fls. large, with scarlet sepals and yellow petals; spurs spreading, long and slender.—A supposed hybrid with *A. chrysantha*. F.M. 1877:278. V. 2:33 f. 2. Var. *rùbraplëno*, Hort. (var. *flöre-plëno*, Hort.). Fls. as in var. *hybrida*, but several whorls of petal-limbs. Var. *nana-álba*, Hort. Fls. pale, often nearly white: plant not exceeding 1 ft.

Var. *truncata*, Baker (*A. truncata*, Fisch. *A. californica*, Lindl.). Fls. with short, thick spurs and very small sepals and a small petal-limb. Intro. 1881. F.S. 12:1188 (as *A. eximia*, Hort.).

294. *Aquilegia chrysantha*. ( $\times \frac{1}{4}$ )

12. *Skinneri*, Hook. St. 1–2 ft. high, many-fld., glabrous: root-lvs. long-petioled, with both primary and secondary divisions long; lfts. cordate, 3-parted; several st.-lvs. petioled and biternate: sepals green, keeled, lanceolate, acute, never much spreading,  $\frac{3}{4}$ –1 in. long; petal-limb greenish orange, half as long as sepal; spur bright red, tapering rapidly, over 1 in. long; stamens protruding far beyond the limb; styles 3: fr., at least when young, bearing broad, membranous, curled wings. After flowering, the peduncles become erect. July–Sept. Mts. of New Mex. B.M. 3919. P.M. 10:199. B.H. 4:1. F.S. 1:6. V. 2:33 f. 5 (poor).—A handsome plant requiring a light soil in a sunny border. Var. *flöre-plèno*, Hort. Fls. double. Gt. 34:57.—Very fine.

295. *Aquilegia longissima*. ( $\times \frac{1}{2}$ )

BBB. Spurs very long, several times the length of petal-limb.

13. *chrysántha*, Gray (*A. leptocèras* var. *chrysántha*, Hook.). Fig. 294. Height 3–4 ft.: root-lvs. with twice 3-branched petioles, lfts. biternate; st.-lvs. several, petioled: fls. many on the plant, 2–3 in. across; sepals pale yellow, tinted claret, spreading horizontally; petal-limb deep yellow, shorter than the sepals, and nearly as long as the head of stamens; spur rather straight, very slender, divergent, about 2 in. long, descending when fl. is mature: follicles glabrous, 1 in. long; style half as long. May–Aug. New Mex. and Ariz. Gn. 16: 264; 51, p. 385. B.M. 6073. R.H. 1896, p. 108. F.R. 2:169. Gt. 33:84. G.C. 1873:1501. F.M. 1873:88. V. 2:33 f. 3. F.S. 20:2108. H.F. 4:120. H.U. 3, p. 324. Var. *flavescens*, Hort. (*A. aurea*, Junk. *A. canadensis* var. *aurea*, Roetzl.). Fls. yellow, tinged with red; spurs incurved, and shorter than in the type. Gt. 21:734. Var. *álba-plèna*, Hort. (var. *grandiflora álba*, Hort.). Fls. very pale yellow or nearly white, with two or more whorls of petal-limbs. Intro. 1889. V. 12:311. G.W. 8, p. 375. Var. *nàna*, Hort. (*A. leptocèras* var. *lutea*, Hort.). Like the type, but plant always small, not exceeding  $1\frac{1}{2}$  ft. Var. *Jäschkani*, Hort. About the same height as last: fls. large, yellow, with red spurs.—Thought to be a hybrid of *A. chrysántha*  $\times$  *Skinneri*, hence sometimes called *A. Skinneri* var. *hybrida*, Hort.

14. *longíssima*, Gray. Fig. 295. Tall, somewhat pubescent with silky hairs, or smoothish: root-lvs. biternate, even in the petioles; lfts. deeply lobed and cut, green above, glaucous beneath; st.-lvs. similar, petioled: fls. pale yellow, sepals lanceolate, broadly

spreading, 1 in. or more, the spatulate petals a little shorter, about equaling the head of stamens; spur with a narrow orifice, 4 in. long or more, always hanging. Distinguished from *A. chrysántha* by its longer spur with contracted orifice, by the narrow petals, and by the late season of flowering. Late July to Oct. 1. Ravines S. W. Texas into Mex. G.F. 1:31 (adapted in Fig. 295).—The seed must be obtained from wild plants, as those cult. usually fail to produce seed; hence not much used.

AAA. Sepals  $1\frac{1}{4}$ – $1\frac{1}{2}$  or even 2 in. long; expanded fls.  $2\frac{1}{2}$ –3 in. diam.; stamens not protruding.

B. Spurs long and not incurved.

15. *cærùlea*, James (*A. leptocèras*, Nutt. *A. macrantha*, Hook & Arn.). St.  $1\frac{1}{2}$  ft., finely pubescent above, bearing several fls.: lower st.-lvs. large and biternate; basal-lvs. with long 3-branched petioles; lfts. 3-lobed on secondary stalks: fls. 2 in. across, whitish, but variously tinted with light blue and yellow; sepals often blue, oblong, obtuse, twice as long as the petal-limb; spurs long, slender, knobbed at the end, rather straight, but curving outward; head of stamens equaling the petals: follicles pubescent, 1 in. long; style  $\frac{1}{2}$  in. Apr.–July. Lower mt. regions, Mont. to New Mex. B.M. 4407; 5477. Gn. 16:264. Mn. 6:61. V. 2:33 f. 4. F.S. 5:531. F.R. 10:165. Gn. 59, p. 147. G. 28:241. Var. *álba*, Hort. Fls. of same size but entirely white. Intro. 1883. Var. *hybrida*, Hort. Sepals some shade of blue or pink, or mixed, and petals nearly white or yellow, also called var. *lutea*, Hort. The true form of this is probably *A. cærulea*  $\times$  *A. chrysántha*. Gn. 51, p. 385. R.H. 1896:108. A.G. 15:315. I.H. 43:61. Var. *Helenæ*, Hort., is very probably a form of this hybrid; very robust, fls. numerous, blue and pure white. G.W. 6:212. Var. *flöre-plèno*, Hort. Fls. longer and very showy, more or less doubled toward the center.

BB. Spurs incurved and hardly longer than petal-limbs.

16. *alpina*, Linn. (incl. var. *superba*, Hort.). Fig. 296. St. nearly 1 ft. high, finely pubescent upwards, 2–5-fld., bearing petioled, biternate lvs.: partial-petioles of basal-lvs. 1–2 in. long, with 3 nearly sessile divisions, deeply lobed: expanded fl.  $1\frac{1}{2}$ –2 in. across, blue, rarely pale or white; sepals  $1\frac{1}{4}$  in. long, half as broad, acute; petal-limb half as long as sepals, often white; spur stout, incurved, same length as the limb; head of stamens not protruding: follicles pubescent, 1 in. long; style much shorter. May, June, Switzerland. L.B.C. 7:657. Gn. 9:384. F.W. 1879:353. B.M. 8303. Var. *álba*, Hort. Fls. pure white.

17. *glandulösa*, Fisch. Fig. 297. St.  $1\frac{1}{2}$  ft. high, glandular pubescent in the upper half, 1–3-fld.: partial-petioles of root-lvs. 1–2 in. long, each with 3 distinct divisions; lft.-segms. narrow and deep; st.-lvs. few, bract-like: fls. large, nodding; sepals bright lilac-blue, ovate, acute, about  $1\frac{1}{2}$  in. long and half as broad; petal-limb same color, but tipped and bordered with creamy white, less than half the length of the sepals, very broad; spur very short,  $\frac{1}{4}$ – $\frac{1}{2}$  in., stout, much incurved; stamens

296. *Aquilegia alpina*. ( $\times \frac{1}{4}$ )

not protruding: follicles 1 in. long, 6-10 in number, densely hairy, with short, falcate style. Allied to *A. alpina*, but a taller plant, with shorter spurs, larger fls., and a greater number of follicles. May, June. Altai Mts. of Siberia. B. 5:219. F.W. 1871:353. Gn. 15:278; 45, p. 193; 64, p. 26. Gt. 289 f. 1.—One of the handsomest.

297. *Aquilegia glandulosa*. ( $\times \frac{1}{4}$ )

Var. *jucunda*, Fisch. & Lall. Fls. rather smaller than in the type; petal-limb white, more truncate at the tip; stamens as long as limb. B.R. 33:19. F.S. 5:535.—A fine variety, with some tendency to double.

18. *Stuartii*, Hort. A recorded hybrid of *A. glandulosa*  $\times$  *A. vulgaris* var. *olympica*. Fls. very large and beautiful. It very much resembles the latter in form of sepals and petals, and the former in shape of spurs and coloration. May, June. Intro. 1891. Gn. 34:344; 61, p. 409. G.M. 54:416.

19. *caryophylloides* is a garden name given to some very mixed forms, with a great variety of colors. Special characters seem not to be well fixed.

*A. baikalensis*, Hort. Fls. large, violet-blue, spurs long.—*A. haydnensis*, Hort., and its var. *delicatissima*, Hort., are much like *A. chrysantha*, and resemble it in habit and color of fls. but the spurs are not so long.

K. C. DAVIS.

**ARABIS** (*Arabia*). *Cruciferae*. ROCK-CRESS. Small perennial or annual herbs, with white or purple flowers, grown mostly on borders and in rockwork.

Flowers mostly in terminal spikes or racemes, small, but often many or appearing for a considerable period of time: lvs. mostly undivided: siliques long, linear, flat: stigma 2-lobed.—In temperate regions, about 100 species, several native to this country; some of them are alpine. Usually prop. by division; also by seeds and cuttings. Hardy, requiring plenty of sun, and thriving even in poor soil. The following four species are perennials:

A. Fls. purple or rose.

*muralis*, Bertol. (*A. rosea*, DC.). A foot high, with a rather dense raceme of pretty fls.: lvs. oblong, sessile (the radical ones with a long narrow base), prominently and distantly blunt-toothed, sparsely pubescent. Spring and summer. Italy. B.M. 3246.

AA. Fls. white.

*serpyllifolia*, Vill. (*A. nivalis*, Guss.). Tufted, 2-6 in.: radical lvs. entire or few-toothed, the st.-lvs. small and sessile, not clasping: fls. in a short cluster, the calyx as long as the peduncle, the limb of the petals linear-oblong and erect. Eu.

*albida*, Stev. (*A. caucásica*, Willd.). Fig. 298. A few inches high, pubescent: lower lvs. narrow at the base, the upper auriculate-clasping, all angle-toothed near the top: fls. in a loose raceme, the calyx shorter than the pedicel, the petal-limb oval and obtuse. Eu. B.M. 2046. Gn. 62, p. 280; 72, p. 67; 74, p. 620. F.E. 16:611.—Blooms early, is fragrant, and is well adapted for rock-gardens and edgings, and covering steep banks.

Var. *flöre-plèno*, Hort. Double. Gn. 65, p. 306. Var. *variegata*, Hort., has yellow-white stripes on lvs. Gt. 45, p. 108. Var. *Billardièri*, Boiss. (*A. Billardièri*, DC.). Hoary-pubescent, slender: lvs. small, very obtuse, entire or with 1 or 2 teeth at base: pod long, slender and spreading: fls. often tinged. Eastern. Gn. 63, p. 422.

*alpina*, Linn. Fls. smaller than in the last, plant only slightly pubescent and hairy: lvs. somewhat clasping but not auriculate; small-toothed nearly or quite the entire length, the cauline ones pointed. Eu. B.M. 226. G.C. III. 30:239.—Blooms very early, and is one of the best rock-plants. Var. *variegata*, Hort. Var. *nana compàcta*, Hort., a dwarf form. Gt. 44, p. 203. Var. *flöre-plèno*, Hort. Fls. full-double; handsome. Gt. 51, p. 211. G. 26:199.

*A. arenosa*, Scop. Fls. rose varying to white: lvs. pinnatifid, those on the st. deep-toothed. Eu.—*A. aubrietoides* Boiss. Much like *A. albida*, but pale pink. Cilicia.—*A. blepharophylla*, Hook. & Arn. Fls. large, rose-purple: lvs. sharp-toothed, sessile or clasping, the margins hairy. Calif. B.M. 6087.—*A. Ferdinándi-Coburgii*, Kell. & Suenderm. Lvs. gray in rosettes, becoming green in winter: fls. small, yellowish. Macedonia.—*A. lucida*, Linn. f. Fls. white: lvs. shining, obovate, clasping. There is a variegated form. Eu.—*A. mollis*, Stev. Fls. white: lvs. pubescent, large-toothed, the lower ones rounded and long-stalked. Eu.—*A. petræa*, Lam. Fls. white: lvs. toothed, the radical ones often parted, the st.-lvs. oblong-linear. Eu.—*A. præcox*, Walldst. & Kit. = *A. procurrens*.—*A. procurrens*, Walldst. & Kit. Fls. white: lvs. ciliate, those on the st. entire and sessile, the others stalked: stoloniferous. A variegated form. Eu.—*A. Stuartii*, Hort. A compact but vigorous garden form with large clear white fls.—*A. verna*, R. Br. Annual, hairy: fls. large, purple: lvs. oblong-ovate to round-oblong, the upper ones clasping, rather coarse-toothed. Eu. B.M. 3331. L. H. B.

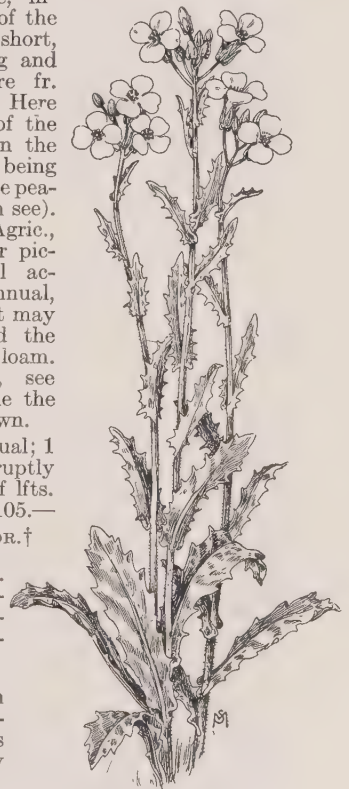

**ARACHIS** (Greek, *without a rachis*). *Leguminosæ* PEANUT. GOOBER. The peanut is sometimes grown in the economic house of botanical gardens, and also as a curiosity in outdoor gardens. The genus has nine species, of which eight are Brazilian. Lvs. abruptly pinnate: fls. 1-3, yellow, in a dense, axillary, sessile spike; ovary stipitate, inclosed within the tube of the calyx, the stipe at first short, subsequently elongating and carrying the immature fr. beneath the ground. Here develops what is one of the most anomalous frs. in the whole Leguminosæ, it being wholly indehiscent,—the peanut of commerce (which see). See also Cyclo. Amer. Agric., Vol. II, pp. 514-519 for pictures and agricultural account. As a hothouse annual, the seeds of the peanut may be sown in heat, and the plants potted in sandy loam. For outdoor culture, see *Peanut*, by which name the plant is commonly known.

*hypogæa*, Linn. Annual; 1 ft. or less high: lvs. abruptly pinnate, with 2 pairs of lfts. and no tendrils. Mn. 7:105.—Procumbent. N. TAYLOR.†

**ARACHNANTHE**. (Greek for *spider-flower*). *Orchidææ*. Included under *Renanthera*.

**ARALIA** (derivation obscure). *Araliææ*. Ornamental herbs, shrubs or trees grown chiefly for their bold foliage.

Stems often spiny: lvs.

298. *Arabis albida*. ( $\times \frac{1}{2}$ )

alternate, deciduous, pinnate to 3-pinnate; fls. small, whitish, in umbels usually forming panicles; pedicels articulate; calyx-lobes minute; petals imbricate in bud; stamens 5; ovary 5-, rarely 2-celled, with the styles free or connate only at the base: fr. a berry-like drupe with 2-5 compressed stones.—About 20 species in N. Amer., Asia, Malay Archipelago and Austral.

The aralias are large herbs, shrubs or small trees, often spiny, with large decompound foliage, small whitish flowers in umbels forming large terminal panicles and followed by small usually black berry-like fruits.

The species are hardy or nearly hardy North. They prefer rich or heavy soil. They are often planted as single specimens on the lawn for the bold subtropical effect of their foliage. Propagation is by seeds sown in spring, which do best with slight bottom-heat, or by root-cuttings, also with bottom-heat.

There are also a number of tender shrubby

plants cultivated as ornamental greenhouse or stove plants, which have been provisionally referred to the genus *Aralia*, as their flowers and fruits are not yet known; therefore it has not been possible to determine their true botanical affinity. In the present work they are referred to other genera. They should be looked for under *Polyscias*, *Pseudopanax*, *Schefflera*, *Oreopanax*, *Panax*, *Sciadophyllum*, *Dizygotheca*. Other related genera, perhaps not including any horticulturally important forms, are *Heptapleurum* and *Monopanax*.

A. Prickly shrubs or rarely low trees: lvs. bipinnate, 2-3 ft. long: umbels numerous, in a large, broad, compound panicle: styles distinct.

*spinosa*, Linn. ANGELICA TREE. HERCULES' CLUB. DEVIL'S WALKING-STICK. Sts. very prickly, 40 ft. high: lvs.  $1\frac{1}{2}$ - $2\frac{1}{2}$  ft. long, usually prickly above; lfts. ovate, serrate, 2- $3\frac{1}{2}$  in. long, glaucous and nearly glabrous beneath, mostly distinctly petioled; veins curving upward before the margin. Aug. Southern states north to Tenn. S.S. 5:211. Gn. 50, p. 126.—The stout, armed sts., the large lvs., and the enormous clusters of fls. give this species a very distinct subtropical appearance. Not quite hardy N. Bark possesses medicinal properties.

*chinensis*, Linn. (*A. japonica*, Hort. *A. mandshurica*, Hort. *Dimorphanthus elatus*, Miq. *A. spinosa* var. *canescens*, Franch. & Savat.) CHINESE ANGELICA TREE. Fig. 299. Sts. less prickly, 40 ft.: lvs. 2-4 ft. long, usually without prickles; lfts. ovate or broad ovate, coarsely serrate or dentate, usually pubescent beneath, nearly sessile,  $3\frac{1}{2}$ -6 in. long; veins dividing before reaching the margin and ending in the points of the teeth. Aug., Sept. China, Japan. M.D.G. 1897:461. Gn. 1, p. 561. G.W. 5:509.—In general appearance very much like the former species, but considerably hardier. Grows well also in somewhat dry, rocky or

clayey soil. Var. *glabrescens*, Schneid. (*A. spinosa* var. *glabrescens*, Franch. & Savat. *A. spinosa* var. *canescens*, Sarg. *A. canescens*, Sieb. & Zucc.). Lvs. often prickly above; lfts. glabrous beneath, except on the veins, dark green above. More tender. Var. *mandshurica*, Rehd. (*Dimorphanthus mandshuricus*, Maxim.). St. prickly: lfts. pubescent only on the veins beneath, more sharply and densely serrate than the foregoing variety and hardier. G.C. II. 10:592; 23:313. Var. *variegata*, Rehd. (*A. japonica variegata*, G.C.). Lfts. bordered with white. I.H. 33:609. G.C. III. 31:231. Gn. 63, p. 379. Var. *aureo-variegata*, Rehd. (*Dimorphanthus mandshuricus elegantissimus* fol. var., Hort.). Lfts. variegated with yellow.

AA. Unarmed herbs: styles united at the base.

B. Umbels numerous, in elongated puberulous panicles: 3-10 ft. high.

*racemosa*, Linn. SPIKENARD. Height 3-6 ft.: glabrous, or slightly pubescent: lvs. quinately or ternately decompound; lfts. cordate, roundish ovate, doubly and sharply serrate, acuminate, usually glabrous beneath, 2-6 in. long: fls. greenish white. July, Aug. E. N. Amer. west to Minn. and Mo. B.B. 2:506.—Root-stock employed medicinally; properties similar to those of *sarsaparilla*.

*californica*, Wats. Height 8-10 ft.: resembles the preceding: lfts. cordate, ovate or oblong-ovate, shortly acuminate, simply or doubly serrate: panicle loose; umbels fewer, larger, and with more numerous rays. Calif. M.D.G. 24:343.

*cordata*, Thunb. (*A. edulis*, Sieb. & Zucc.). Height 4-8 ft.: lvs. ternately or quinately decompound, pinnæ sometimes with 7 lfts.; lfts. cordate or rounded at the base, ovate or oblong-ovate, abruptly acuminate, unequally serrate, pubescent on the veins beneath, 4-8 in. long. Japan. Gt. 13:432 (as *A. racemosa* var. *sachalinensis*). R.H. 1896, p. 55. A.G. 13, pp. 6, 7. Young stalks edible: see *Udo*.

*cachemirica*, Deene. (*A. cashmeriana*, Hort. *A. macrophylla*, Lindl.). Height 5-8 ft.: lvs. quinately compound, pinnæ often with 5-9 lfts.; lfts. usually rounded at the base, oblong-ovate, doubly serrate, glabrous or bristly on the veins beneath, 4-8 in. long. Himalayas.

BB. Umbels several or few on slender peduncles; pedicels glabrous: 1-3 ft. high.

*hispida*, Vent. BRISTLY SARSAPARILLA. WILD ELDER. Height 1-3 ft., usually with short, woody st., bristly: lvs. bipinnate; lfts. ovate or oval, rounded or narrowed at the base, acute, sharply and irregularly serrate, 1-3 in. long: umbels 3 or more in a loose corymb; fls. white. June, July. From Newfoundland to N. C. west to Minn. and Ind. B.M. 1085. L.B.C. 14:1306.—Bark diuretic, alterative.

*nudicaulis*, Linn. WILD SARSAPARILLA. SMALL SPIKENARD. Stemless or nearly so: usually 1 lf., 1 ft.

299. *Aralia chinensis*.

high, with 3 quinate pinnate divisions; lfts. oval or ovate, rounded or narrowed at the base, acuminate, finely serrate, 2-5 in. long; umbels 2 or 3; fls. greenish. May, June. Newfoundland to N. C., west to Mo. B.B. 2:506.—Rootstock employed medicinally; properties similar to those of sarsaparilla.

*A. japonica*, Thunb.=*Fatsia japonica*.—*A. papyrifera*, Hook.=*Tetrapanax papyriferum*.—*A. pentaphylla*, Thunb.=*Acanthopanax pentaphyllum*.—*A. quinquefolia*, Decne. & Planch.=*Panax quinquefolium*.—*A. Sieboldii*, Hort.=*Fatsia japonica*.—*A. trifolia*, Decne. & Planch.=*Panax trifolium*. (See also *Ginseng*.)

ALFRED REHDER.

ARATICÚ: *Annona* and *Rollinia*.

**ARAUCÁRIA** (Chilean name). Including *Columbea* and *Eutacta*. *Pinææ*. Large South American and Pacific Australian evergreen trees (about a dozen species), grown in their juvenile state in greenhouses and windows and often used in summer for lawn decoration; they are very decorative pot-plants.

Tall strict or widely branching conical trees: lvs. small, scale-like and stiff, clothing all the branches uniformly and usually closely imbricated; fls. mostly dioecious, the staminate terminal and solitary or disposed in fascicles; anthers 6-8-celled; pistillate fls. in ovoid or globose heads that become large woody cones with only 1 seed underneath each scale.—The South American species (*Columbea*) have scarcely winged scales, the cotyledons 2, and the germination hypogeal (cotyledons remaining below ground); the Australian and Pacific species (*Eutassa*) have winged scales, cotyledons 4, and germination epigeal.

Araucarias are probably the most prized pot evergreens in cultivation. They are much used in house decoration, particularly at Christmas time, as they are not only attractive but will stand much hard usage. *A. excelsa* (Fig. 300) is the one commonly seen in residences. Propagation is by seeds and cuttings, as given under *A. excelsa* below. Symmetrical plants are secured from the leading shoots. Side shoots are likely to make misshapen specimens, as seen in Fig. 301. The arau-

300. A good specimen of *Araucaria excelsa*.

carias need cool treatment. The temperature should not be above 60° at night. If kept too crowded or not given sufficient light, they become ragged and straggling, as in Fig. 302. In summer the plants should be protected from direct burning sun.

The species thrive in the open in southern Florida and in parts of California. *A. imbricata* is the hardiest. It is rarely seen in greenhouses. *A. Bidwillii* is

apparently the second hardiest, and also one of the best species for all purposes. *A. excelsa* and its allies are about as hardy in southern Florida as crotons and acahyphas.

The commonest species in greenhouses is *A. excelsa*. It is grown on an enormous scale in many nurseries for

301. Unsymmetrical *Araucaria excelsa*, grown from a side shoot.

decoration as window or table plants. When raised from seed the plants grow rapidly and the branches are invariably disposed in tiers with wide internodes, often as much as 2 feet separating each tier of branches. Such plants are of little use for ordinary decorative work and recourse is made to plants raised from cuttings. This practice has grown up as it is found that plants raised from cuttings assume a dwarf compact habit, with the tiers of branches placed close together, and that they do not grow into large specimens until many years old. The plants for stock purposes are usually raised from seed, and when they have formed some three to six tiers of branches the tops are taken out and put in as cuttings in light sandy compost in a close house or case at a temperature of about 60° F. They are kept shaded from hot sun and damped over frequently until rooted. The stock plants are kept growing and soon break out into new growth in the axils of each of the upper branches. These are all "leader" growths, and when long enough they each furnish a suitable cutting which is treated in the same way as the primary growth or leader. After each of these has been removed for stock, the stem of the stock plant is cut off to the next tier of branches, which in turn will furnish another set of cuttings and so on until the plant is reduced to the bottom layer of branches, when it is discarded and another stock obtained again from seed. It should be pointed out that the branches themselves may be rooted as cuttings, but they always retain their flat asymmetrical shape and are useless for stock purposes. (See Fig. 301.)

*A. Lvs. (or most of them) awl-like, at least at apex.*

1. *excelsa*, R. Br. NORFOLK ISLAND PINE. Figs. 300-303. Plant light green: branches frondose, lvs. curved and sharp-pointed, rather soft,  $\frac{1}{4}$ - $\frac{1}{2}$  in. long, and densely placed on the horizontal or drooping branchlets. Norfolk Isl. F.R. 2:411.—The commonest species in this country, being much grown as small pot specimens. A blue-green form is cult. as var. *glauca*, (or *A. glauca*). It is a form in which the tips of the growths are white when young; has recently been intro. under the name of "Silver Star." It is a most beautiful plant and sure to have a great future as a market plant. There is also a strong-growing, large variety, with very deep green foliage, var. *robusta*, Hort. Var. *virgata*, Hort., primary branches with no secondary branches, or very short ones. In its native wilds *A. excelsa* reaches a height of over 200 ft. and a diam. of even 9 or 10 ft. The solid, globular cones are 4 or 5 in. diam.

F.S. 22: 2304-2305.—An excellent house plant, and keeps well in a cool room near a window. In summer it may be used on the veranda, but must be shaded.

The timber is used for ship-building.

302. *Araucaria excelsa*, a poor specimen because too crowded or not sufficient light.

and resin. Locally known as hoop pine, Moreton Bay pine, colonial pine, coorong, cumburtu, coonam.

3. *Coëkii*, R. Br. (*A. columnaris*, Hook.). A slender columnar tree, much narrower in shape than *A. excelsa* which it closely resembles when young: branches disposed as in *A. excelsa*, but tree tending to shed the lower ones; branchlets crowded on the branches and turning upwards in a boat-like form: young lvs. alternate and rather closely arranged on the branchlet and  $\frac{1}{4}$  in. long, broad and slightly decurrent at base, slightly curved, mucronate; adult lvs. densely imbricated, short and ovate, obtuse; cones 3-4 in. diam. and somewhat longer. New Caledonia, where it reaches a height of 200 ft., making very straight and imposing shafts. B.M. 4635. A.F. 12:559.—Named for Captain Cook. Var. *aurea*, Hort., has golden-yellow foliage. There is also a var. *glauca*, Hort., with silvery lvs.

303. *Araucaria excelsa*. ( $\times \frac{1}{2}$ )

4. *Balánsæ*, Brongn. & Gris. (*A. elegans*, Hort. Bull.). A dwarf-growing species of slow growth (when grown as a pot-plant) and with few loosely arranged tiers of branches, usually 5 in a tier; branchlets distichous, narrow and deflexed with age: lvs. imbricated, short, stiff;  $\frac{1}{2}$  in. long, falcate, more or less obtuse, dark olive-green in color: male cones cylindrical-conical, 2-3 in. long; female cones globose or elliptic, 4 in. long. New Caledonia.—Rarely grown. The narrowest and most slender-branched species in cult.

AA. Lvs. broader, usually plane and imbricated.

5. *Rùlei*, Muell. Fig. 304. Leafy branchlets very long: lvs. oval-elliptic, imbricated, concave, arched towards the branch, nearly or quite obtuse, with a prominent dorsal nerve, silvery gray on the upper and rich glossy green on the

304. *Araucaria Rulei*. ( $\times \frac{1}{2}$ )

lower side. Variable at different ages. When young, the branches are often drooping and the lvs. compressed and obscurely 4-angled and nearly or quite subulate, var. *polymorpha*, R.H. 1866, p. 350. There is also a var. *compacta*. New Caledonia. Reaching 50 ft. in height. R.H. 1866:390, and plate. I.H.

22:204. A strikingly beautiful plant and somewhat rare in cult. The figure in G.C. 1861:868, is *A. Muelleri*, Brongn. & Gris., a broader-lvd. species. Var. *Goldieana*, Hort. (*A. Goldieana*, T. Moore). A variety with narrower lvs. and with branches rather more erect than the type. F. 1877:39. A var. *elegans*, Hort., is described, with smaller lvs., and close-whorled more slender branches: dwarf.

6. *Bidwillii*, Hook.

Fig. 305. Rather narrow in growth, especially with age, the branches simple: lvs. in two rows, lance-ovate and very sharp-pointed, thick, firm and shining. Austral., where it attains a height of 150 ft., and is known as bunya-bunya. R.H. 1897, p. 500, desc. G.C. III. 15:465, showing the pineapple-like cone.—One of the best and handsomest species for pots.

305. *Araucaria Bidwillii*. ( $\times \frac{1}{2}$ )

7. *braziliæna*, A. Rich. (*A. gracilis*, Hort.). Branches verticillate, somewhat inclined, raised at the ends, tending to disappear below as the plant grows: lvs. alternate, oblong-lanceolate, 1-2 in. long, somewhat decurrent, much attenuated and very sharp-pointed, deep glaucous green, loosely imbricated: cone large and nearly globular. S. Brazil, reaching a height of 100 ft. F.S. 21:2202. Var. *éiegans* (*A. elegans*, Hort.), is a form with very numerous branches and more crowded and often glaucous lvs. Var. *Ridolfiana*, Gord., is a more robust form, with larger and longer lvs.

8. *imbricata*, Pav. MONKEY PUZZLE. Figs. 306, 307. A striking tree of pyramidal habit: branches generally in 5's, at first horizontal, with upward-curving (sometimes downward-curving) tips, but finally becoming much deflexed; branchlets in opposite pairs, curved upward when young, and continuing to grow until several feet long when adult: lvs. imbricated and persisting, even on the trunk, ovate-lanceolate, very stiff, leathery, and sharp-pointed, 2 in. long on the primary st. and branches, 1 in. long on the branchlets, slightly concave at the base, bright green on both sides: cone 6-8 in. diam. Western slope of the Andes in Chile, reaching a height of 100 ft. F.S. 15: 1577-1580. R.H. 1893, p. 153; 1897, pp. 271, 319, desc. Gt. 44:115. G.C. III. 21:288; 24:154.—Hardy in the S. This is the species which is grown in the open in England and Ireland. The hardiest species in cult. Thrives well in a heavy loamy soil in a moist valley or position sheltered from rough winds in mild climates. The branches are heavy and rather brittle and the beauty and symmetry is soon destroyed if planted in an exposed position. The timber is

306. *Araucaria imbricata*. California.

valuable. The seeds constitute the chief food of the aborigines in some sections of S. Amer. Var. *platifolia*, Hort., is a form with very broad lvs.

*A. albospica*, Hort.=*A. excelsa*.—*A. Dombeyi*, A. Rich.=*A. imbricata*.—*A. intermedia*, R. Br. Tall and erect, sparingly

307. *Araucaria imbricata*. ( $\times \frac{1}{2}$ )

branched, nearly denuded of foliage; lvs. sessile, imbricated, cordiform, obtuse, green and shining. New Caledonia.—*A. Lindleyana*, Van Houtte = *A. braziliana*.—*A. montana*, Brongn. & Gris. Tall; lvs. scale-like, curved, ovate, ob-

tusish, more or less concave, with white spots in many series. New Caledonia.—*A. Muelleri*, Brongn. & Gris. Lvs. almost flat, with whitish spots in series. New Caledonia.—*A. Niepráskui*, Bau-

mann. Branches wide-spreading with long drooping side branches; perhaps a form of *A. Rulei*. R. B. 31: p. 132.—*A. subulata*, Vieill. Like *A. intermedia*, but trunk less naked, and lvs. linear-subulate. New Caledonia.

C. P. RAFFILL.

**ARBORETUM.**—A living collection of trees and other woody plants.

Collections of trees have found a place in the botanic gardens of all countries since the physic garden at Tokyo was founded eight hundred years ago; and for more than three centuries individuals have made such collections for the decoration of estates or for purposes of study. In Europe the largest collection of the woody plants of temperate regions is found in the Royal Gardens at Kew; and in the Dutch Colonial Garden at Buitenzorg on the island of Java is the most important collection of the trees of the tropics. Small experimental arboreta composed chiefly of timber trees of supposed value have been planted in connection with most of the forest schools or forest institutes of Europe.

#### Historical sketch.

As early as the middle of the sixteenth century, a collection of trees was made at Touvoye in France by René du Bellay, Bishop of Mans, who received the seeds of a number of exotic trees from Pierre Belon, physician and traveler, who first brought to Europe some of the trees of western Asia. In its day, the garden at Touvoye was pronounced by the botanist Gesner the richest and most beautiful in France, Germany and Italy. Like most of the early collections of trees made by individuals, all traces of the trees planted by René du Bellay have disappeared.

Nearly two centuries later, the head of the French Marine, Duhamel du Monceau, a man of scientific attainments, wealth and social influence, gathered from Europe and North America large collections of trees on his two estates of de Veigny and du Monceau and formed what must be considered the first arboretum made with scientific purpose. Du Monceau undertook a critical study of his collections and published in 1755 his "Traité des arbres et arbustes qui se cultivent en France." His arboretum is said to have contained a thousand species of woody plants belonging to one hundred and ninety-one genera. Duhamel's publications and example had much influence and led to the introduction of many exotic trees into French parks and plantations. Noble specimens of the cedar of Lebanon, the deciduous cypress of the southern United States and other trees planted by him, are still living.

The arboretum established in 1825 in France at Les Barres near the village of Nogent-sur-Vernisson (Loiret) by Pierre Philippe André de Vilmorin is still one of the most important dendrological stations in Europe. Vilmorin was especially interested in the different geographical forms or varieties of the principal timber trees of Europe and made large plantations of these and of a number of exotic trees. In 1866, after the death of the founder, the arboretum at Les Barres was purchased by the French Government and now, greatly improved

and enlarged by new plantations, is known as the Arboretum National des Barres and is used as a school of sylviculture. In 1906 a critical catalogue of this collection, prepared by Monsieur L. Pardé, Inspector des Forêts, and accompanied by an atlas of plans of the arboretum and pictures of many of its principal trees, was published in Paris. The value of the arboretum at Les Barres has been increased by the formation in its immediate neighborhood of the Fruticetum Vilmorinianum. This collection of shrubs, which is the most complete in Europe, was established in 1894 by the grandson of the founder of the arboretum at Les Barres, Monsieur Maurice L. de Vilmorin, who has been successful in introducing many interesting plants into gardens through his relations with French missionaries in China. A catalogue of the Fruticetum Vilmorinianum was published in 1894.

In 1857 Monsieur Alfonse Lavallée began to plant an arboretum at Segrez in the Department of Siene-et-Oise. This was a scientific enterprise and the value of the living collections was increased by the establishment at Segrez of a botanical library and herbarium. Aided by the professors of the Museum d' Histoire Naturelle in Paris, it had become in 1875, when the "Enumération des Arbres et Arbrisseaux Cultivés à Segrez" was published, one of the largest collections of woody plants that had been made up to that time. This catalogue was followed in 1880 by the "Arboretum Segrezianum" in which appear critical descriptions and figures of some of the rare plants cultivated at Segrez. Six parts with thirty-six plates of this work appeared. M. Lavallée died suddenly in 1884 and his publications and a few trees in the park at Segrez are the only monuments left of his zeal and industry in the study of trees. In 1858 Monsieur G. Allard began the arboretum at la Maulévie, near Angers in France, which he still maintains, and which contains one of the largest and most interesting collections of the oaks of Europe and southwestern Asia in the world, and is particularly rich in conifers.

At Muskau in the valley of the Neisse in Silesia, on the estate made famous by the beauty of arrangement given to it by Heinrich Hermann von Puckler, an important arboretum was established by Prince Frederick of the Netherlands, who purchased the Muskau estate in 1845. The critical catalogue of the plants in the Muskau Arboretum by Petzold & Kirchner, published in 1864, and entitled "Arboretum Muscaviensis," is a standard work on cultivated trees and shrubs. Many of the trees planted by von Puckler are still living, but the arboretum is now conducted as a commercial nursery.

In Great Britain, no important scientifically managed collection of trees and shrubs, with the exception of those connected with general botanic gardens, has been attempted. The arboreta, however, connected with the

308. Old Deciduous Cypress in Bartram's Garden. This tree still stands, although dead.

national gardens at Kew, Edinburgh and Dublin have greatly increased the knowledge of trees and stimulated the taste for planting not only in Great Britain but in all civilized countries. At Kew is to be found probably the largest number of species of trees and shrubs which has yet been gathered together, for in England more plants can be made to grow together than flourish in any one country on the continent of Europe or in any one place in the United States. Kew, as a garden in connection with royal residences has existed since the middle of the sixteenth century; in 1841 it was created a national garden and its growth and improvement have continued uninterruptedly ever since. In the older parts of the garden many noble trees testify to the age of the establishment, but it was not until 1848 that the systematic planting of an arboretum was begun by Sir William Hooker, the first director of the national garden. The reputation of the succeeding directors of Kew, its scientific standing and the interest of the nation in its garden have made it possible to gather there plants from all parts of the world; and although much of the soil occupied by the arboretum is not well suited for the growth of trees, and the smoke of the city makes the cultivation of conifers and many other evergreen plants difficult and sometimes impossible, every serious student of trees must avail himself of the great opportunities for study which this arboretum affords. A collection of trees was once planted by the Horticultural Society of London at its gardens in Chelsea; this was given up by the Society many years ago. On many of the large private estates in England, Scotland and Ireland there are important arboreta; and the desire of the owners of British estates to cultivate new trees, especially conifers, stimulated the botanical explorations in all the temperate parts of the world in the first half of the nineteenth century undertaken by the Horticultural Society of London and by some of the large firms of European nurserymen. Some of these private collections have been of great value to students.

In connection with the Quinta Normale and the Museum of Natural History in San Diego in Chile is a small but remarkable arboretum in which are found the oaks, hickories, magnolias and other trees of eastern North America flourishing as they flourish nowhere else outside the United States, and with these the poplars and birches of northern Europe are growing with the cypresses and pines of California, and the eucalypti of Australia.

Few interesting collections of trees have been made in North America. In 1728 John Bartram, a Pennsylvania farmer and later distinguished as a traveler and botanist, purchased a piece of land on the banks of the Schuylkill River about three miles from Philadelphia and established a botanic garden, in which he planted a number of American trees collected in his various journeys, which extended from the shores of Lake Ontario to Florida, or received from his correspondents in Europe; among these were some of the famous botanists of the day. Bartram was appointed botanist to the King of England and, through his labors, many American trees were introduced into England and many Old World plants first reached America. Bartram died in 1777. Later his garden was used as a nursery and, after having passed through the hands of various owners, was bought in 1891 by the city of Philadelphia and is now a public park. A few only of the trees planted by John Bartram are now standing. Fig. 308.

Bartram by his own labors and through his European correspondents attained much influence, and is one of the most interesting figures among those who have increased the knowledge of American trees. Not the least important of his good works was the inspiration which his cousin, Humphrey Marshall, another Pennsylvania farmer, derived from his example and advice. Marshall in 1773 made a garden and planted a number

of trees near the Bradford Meeting-house now in the village of Marshalltown, a few miles from West Chester, traveled widely to study and collect plants, and in 1785 published the "Arbustum Americanum," a description of the trees and shrubs indigenous to the United States. This was the first book on plants written by a native-born American. Many of the trees planted by Marshall have grown to a great size and are still in a flourishing condition. His arboretum is now the most interesting of the old collections of American trees.

The garden and arboretum planted about 1830 by John Evans, another Pennsylvanian, in Delaware County about twelve miles west of Philadelphia, contained for many years one of the largest collections of plants in the United States. Evans kept up an active correspondence with Sir William Hooker, the Director of the Royal Gardens at Kew, from whom he received the seeds of many Himalayan and other rare and little-known plants. A few only of the trees planted by Evans, who died in 1862, are now alive; among them is probably the largest specimen of the European hop hornbeam in the United States.

In 1841 Henry Winthrop Sargent, of Boston, bought Wodenethe, an estate of twenty-two acres above Fishkill Landing, New York, overlooking the Hudson River. A friend and pupil of his neighbor, A. J. Downing, Sargent through Downing's influence became interested in the cultivation of trees and especially of conifers. At Wodenethe every coniferous plant that could be obtained was tested, and for forty years it remained the most important place in the United States for obtaining information on the value of these plants for cultivation in this country. If the results of Sargent's experiments were largely negative, that is if they were more successful in showing what trees were not suitable for the eastern states than in adding numerous species to the number of conifers which can be permanently grown here, they were of great interest and value to the country. For many years the influence of H. W. Sargent among lovers of country life in the United States was considerable and has done much in the last sixty years toward increasing the knowledge of trees and directing sound horticultural taste. To this influence is largely due the horticultural careers of his relatives, Horatio Hollis Hunnewell and Charles Sprague Sargent.

In 1852 Mr. Hunnewell began the development of an estate in the valley of the Charles River at Natick (now Wellesley), about twelve miles west of Boston. Here, with the aid of his relative at Wodenethe, he planted coniferous trees for which the well-drained gravelly soil proved to be suited. Past middle life when he began to plant his trees, he was able to see many of them attain a large size and his pinetum, in number of species and beauty of individuals, the most important in the United States. In the hands of a younger Hunnewell, it is constantly enlarged and improved, and Wellesley is still one of the most interesting places in America for the lover of cultivated trees.

About 1870 Josiah Hoopes, author of "The Book of Evergreens," the only American book on the subject, planted in connection with his nursery in West Chester, Pennsylvania, a large number of coniferous trees. This at the time was one of the best collections of these plants that had been made in the United States. Twenty-five years later, and after Mr. Hoopes' death, although a large number of the species had disappeared, many survived to show their beauty and value as ornamental trees. The Hoopes pinetum should be visited by everyone interested in the cultivation of conifers.

In 1874 Charles A. Dana, the distinguished journalist, bought Dosoris, an island about fifty acres in extent off the north shore of Long Island, near Glen Cove, and began planting trees. Great intelligence and industry was shown in this undertaking, and in the Dosoris collection are still found many rare trees and

shrubs of exceptional size and beauty; but with the change of owners this, like most private collections of trees in the United States, is probably destined to suffer from neglect or to entirely disappear."

In Highland Park, Rochester, New York, on grounds admirably situated for the purpose, the park department of that city has established an arboretum which contains one of the largest collections of trees and shrubs in the United States and which, situated as it is in a great center of commercial horticulture, cannot fail to become a powerful factor in horticultural education. Equally important in educational possibilities is the excellent arboretum which has been established by the Government of the Dominion of Canada on its Central Experimental Farm at Ottawa. Placed in a region of great winter cold, the lessons which the Ottawa Arboretum can teach of the hardiness of plants will be of special value to Canada and to the northern borders of the United States.

The influence of American nurserymen by their introduction and multiplication of trees and shrubs must not be overlooked, and American lovers and students of trees will always gratefully remember such names as Kenrick and Hovey of Massachusetts, Price and Parsons of Long Island, Ellwanger and Barry of Rochester, New York, Thomas Meehan of Pennsylvania, Berckmans of Georgia, and Robert Douglas of Illinois. The arboreta which they planted in connection with their nurseries offered in their time valuable object lessons, and the influences of their publications are often of lasting value.

*The Arnold Arboretum. Figs. 309-311.*

It has been left to Harvard University to establish an arboretum on a large scale and in a manner which seems destined to make it permanent. This arboretum owes its origin to Mr. James Arnold, a merchant of New Bedford who died in 1868, leaving to the trustees of his estate \$100,000 to be devoted to the advancement of agriculture or horticulture. One of these trustees was George B. Emerson, the author of "The Report on the Trees and Shrubs of Massachusetts." Mr. Emerson, realizing the benefit which the world might derive from the establishment of a scientifically managed collection of trees in the neighborhood of Boston, proposed to turn over Mr. Arnold's legacy to the President and Fellows of Harvard College to be used to develop and maintain an arboretum, provided they would devote to this purpose a part of the farm in West Roxbury which had been given to the university by Mr. Benjamin Bussey. This plan was carried out in 1872, and 125 acres were set aside for the Arnold Arboretum, in which the University undertook to grow a specimen of every tree and shrub able to support the climate of eastern Massachusetts. In December, 1882, a contract was made between the university and the city of Boston under which the city agreed to add certain adjoining lands to the arboretum, to construct and maintain under the direction of its park commission a system of carriage-drives and walks

309. Map of the Arnold Arboretum, Jamaica Plain, Mass., a Department of Harvard University.

planned under the direction of Frederick Law Olmsted, to police the grounds and to assume all taxes which might be levied on the property during the thousand years for which the contract was made. In return for this assistance, the university agreed to open the arboretum to the public from sunrise to sunset during every day of the year, reserving, however, entire control of all the collections and of the grounds with the exception of the drives and walks. Work on the roads was begun by the city in 1885, but through various delays in construction, the planting of the principal collections of trees and shrubs was not undertaken until the following year. In 1894, seventy-five acres, known as Peter's Hill, and a part of the Bussey farm, were added to the arboretum by the President and Fellows of the university, and in 1898 were opened to the public by an encircling road built by the park department of the city. This contract with the city of

been understood by its management, is to increase the knowledge of trees and other woody plants. To accomplish this, something more than the collection of living plants hardy in eastern Massachusetts contemplated by the trustees of James Arnold's will was necessary, and the Arnold Arboretum as now organized is, first, an out-of-door museum in which the public can see the trees and shrubs of the north temperate zone conveniently arranged; second, a dendrological station and laboratory in which the scientific study of trees is carried on, and third, a bureau of publication, exploration and exchange through which botanical exploration in different parts of the world is undertaken and the results and products of these explorations made known and distributed.

In the arrangement of the out-of-door museum—the living collection of trees and shrubs—the species to facilitate study have been arranged in groups of genera

310. *Kalmia* in bloom at the Arnold Arboretum.

Boston is of great value to the arboretum, for, as it cannot be moved from its present location without the consent of the university and the city, there is little chance that, however valuable the land may become, the people of Boston will ever consent to give up a public park of unusual character and great beauty. The assumption of all taxes by the city during 1,000 years insured by this contract may become an important contribution to the arboretum.

The Arnold Arboretum occupies 220 acres of meadow, hill and valley. It forms one of the series of Boston parks with which it is connected by a broad parkway. It is close to the Forest Hills station of the New York, New Haven & Hartford Railroad, and it can be reached from all parts of the city by two lines of electric cars. Its natural features are a broad meadow along the northeastern boundary, and three high hills separated by narrow valleys through one of which flows a small stream. One of these hills is covered by a remarkable growth of hemlock trees, and natural woods, in which large individuals of many of the trees of eastern New England are found, cover other parts of the arboretum.

The purpose of the Arnold Arboretum, as this has

and families in a natural sequence whenever conditions of soil and situation have made this possible, a further attempt being made to arrange the planted groups in harmony with the native woods and the other natural features of the ground. All the groups of trees, shrubs, and all the natural woods are easily reached by grass paths which extend to all parts of the grounds. In the case of the trees of North America, several individuals of each species have been planted, but want of space has generally made it impossible to plant more than one individual of an Old World species. In the groups of American trees, one specimen is planted with abundant space for the full development of its branches and the others are arranged in a compact group to show their habit under such conditions.

For the convenience of students, the shrubs of genera in which there are no hardy trees, and all vines, have been arranged in a sequence of genera in long parallel beds near one of the principal entrances; but the shrubs belonging to genera in which some of the species are hardy trees have been planted in connection with the groups of trees of these genera. In addition to the shrubs in the general shrub collection, supplementary

collections of several of the large genera of shrubs have been established, usually in sheltered positions, in which are planted new or imperfectly known species or species that require unusual care or special protection.

The collections of the Arnold Arboretum are rich in the woody plants of eastern North America, northern Europe, Siberia, China and Japan, and contain the largest number of species and varieties of these plants to be found in any American collection; and gradually the Arboretum, with its hills and valleys, its native woods and varied vegetation, has developed into one of the most beautiful of all the public gardens of the world.

A large part of the trees and shrubs planted in the Arboretum has been raised in its nurseries from seeds collected in those parts of the region occupied by the species in which the climate most resembles that of New England. A record of the origin and history of all the plants is kept on the cards of a catalogue, and the position of every tree permanently planted in the groups is recorded on the sheets of a large scale map, and with this is kept the detailed history of each tree. Labels giving the Latin and English names and the region that they inhabit are placed at the height of the eye on the trunks of prominent native trees standing near drives and walks, and these labels are found on the trunks of many of the planted trees in the different groups. Metal labels with raised letters are used for the plants in the shrub collection and for shrubs and small trees near some of the walks. Wooden stakes giving their names are placed before many shrubs and small trees; and to every plant, whether otherwise labeled or not, a small zinc label is attached.

In order to make the Arnold Arboretum a scientific station and something more than a collection of living trees, an herbarium of woody plants intended eventually to represent the ligneous vegetation of the world and a library now containing 29,000 bound volumes and 6,000 pamphlets have been formed. An herbarium and library connected with such an institution are essential for the determination and correct labeling of the living collections and make possible original scientific work. A report on the forest wealth of the United States, the reports of state and national commissions appointed to study American forest conditions, the illustrated "Silva of North America," the "Manual of the Trees of North America," a "Forest Flora of Japan," "Trees and Shrubs," a monograph of the genus *Lonicera*, a monograph of the pines of Mexico, many of the articles on trees and shrubs in this Cyclopaedia, the ten volumes of Garden and Forest, the Jesup collection of North American woods in the American Museum of Natural History in New York, are some of the contributions to knowledge which the arboretum as a scientific station has been able to make. For several years, it has been actively engaged in bibliographical studies, and the results of these studies are being published in the "Bradley Bibliography," of which two volumes have appeared. An elaboration of the woody plants of China is in progress, based largely on the collections of E. H. Wilson, one of the arboretum explorers, and is now being published by the arboretum in the "Plantæ Wilsonianæ."

In connection with its work in search of material for its collections, officers and employees of the arboretum have visited nearly every part of North America, have traveled in Peru and Chile, and explored the Caucasus, Japan, Korea, and northern and western China. Through these explorations, the Arnold Arboretum has been able to introduce into the gardens of the United States and Europe a large number of new plants or plants that have been long lost to cultivation, and through these introductions it has established relations in all countries with the principal botanic gardens, the important nurserymen and many individuals interested in trees and their cultivation.

The work the Arnold Arboretum attempts and the demands which are made on it are national in scope and extent, but for a national American arboretum a more temperate and equable climate than that of Massachusetts is desirable. Its situation, however, in the midst of a population famous for its generosity and actively interested in horticulture, and the stability it enjoys from its connection with a great university, and from its contact with the city of Boston, are favorable to it. It is impossible, however, to cultivate in one collection the trees which grow naturally or can be made to grow in all the different regions of the United States, and the American national arboretum of the future must first of all be an institution, like the Arnold Arboretum,

of long life and continuous control; and this central institution properly equipped with laboratories and material for research must be in a position to establish branches in Florida, Arizona, California and in some central regions of the continent, for in such branches managed by the central institute, it would be possible to collect and to study nearly all the trees of the world suitable for

311. Trees still standing in the Humphrey Marshall collection.

different parts of the country, and so make possible in the United States an arboretum really national in character.

Herbaria are chiefly valuable when they supplement collections of living plants; and it is now becoming gradually acknowledged that accurate knowledge of trees and of many other groups of plants can be obtained only by a comparative study of the plants themselves. The opportunity for this will be found only in establishments in which plants in large groups can be assembled and grown under conditions favorable for their best development. Today the palms of the tropics, especially those of the Old World, can be satisfactorily studied only in the great collection of these plants gathered together in the botanic garden at Buitenzorg in Java. Some groups of northern trees and shrubs can now best be observed in the Arnold Arboretum, but to obtain exact information of others the student must make long and sometimes difficult journeys. Until, for example, collections of the cactaceæ and of plants like the agaves and yuccas are assembled in a region favorable to their growth, like southern New Mexico or Arizona, it will be impossible to obtain a true understanding of these plants which, when grown in northern greenhouses or in regions unsuited to their peculiar needs, more often mislead than illuminate. Comprehensive collections of the species of eucalyptus, acacia and other Australasian plants established in California would be of great value to that state; and collections of tropical and subtropical plants in southern Florida would immensely benefit not only

the southern part of that state but all the West Indies and other tropical countries.

#### *A nationalized arboretum.*

The arboretum, therefore, worthy to be considered national in scope and accomplishment in a country of such varied climates as North America must consist of a number of stations in different parts of the country under one management and with one central head from which the work of the different stations should be directed and superintended and which should be the bureau of publication of the results obtained in them. The position of the central station in the country is of little importance in comparison with its permanence, endowment and freedom from all dangerous influences. Such conditions of permanence and freedom in this country will best be obtained in connection with one of the great endowed universities rather than with the national or with any state government, for political association is not conducive to the best scientific research, and for the next hundred years at least, and until a real knowledge of the vegetation of the earth has been obtained, the National Arboretum must be organized primarily for research.

By the information it could accumulate, such an institution would be able to aid the agricultural experiment stations and state universities, which are the natural and proper organizations for popularizing the results of long-sustained scientific investigations, for which they are not equipped and which, with the uncertainty of their resources, they cannot hope successfully to carry on. Forestry and landscape-gardening are based on a knowledge of trees, and in the study of trees are found pleasures which increase with knowledge and endure through life.

The Arnold Arboretum endeavors to popularize its knowledge by the publication of Bulletins of Popular Information and by courses of popular field instruction; and it should further be the duty of a national Arboretum to aid in the establishment of arboreta in connection with agricultural colleges and experiment stations, on the grounds of universities not equipped with botanic gardens, and on the grounds of high-schools. Collections of trees properly labeled are needed in every institution of learning and in every large center of population. Until such collections are established, the people of the United States can hope to know little of the beauty and value of their native trees and of those exotic trees which can safely be introduced into different parts of the country.

C. S. SARGENT.

**ARBORICULTURE.** Arboriculture is the growing or cultivation of trees. It is distinct from silviculture, which grows trees in forest plantations for the production of a timber-crop. Silviculture is a part of forestry.

What constitutes a tree is not easy to explain in a short and well-defined statement. A given species may assume a tree-like habit or remain shrubby, according to the climatic conditions, soil and other circumstances. Usually a tree is defined, under normal conditions, as a woody plant rising from the ground with a single stem and attaining a certain height, fixed by some at 20, by others at 15 feet, or even less. A more exact definition has been given by B. E. Fernow: "Trees are woody plants the seed of which has the inherent capacity of producing naturally within their native limits one main erect axis continuing to grow for a number of years more vigorously than the lateral axes and the lower branches dying off in time."

Trees are the most prominent feature of the vegetable world and surpass all other organic beings in height, magnitude and longevity. The greatest height known has been reached by *Sequoia sempervirens*, which attains 340 feet. Not very far less is *Eucalyptus amygd-*

*dalina*, of which the highest tree actually measured is given as 325 feet; it is, therefore, the tallest of the hardwood trees. The sequoias, however, are of more majestic and gigantic appearance than the eucalyptus on account of their massive trunk (see *Sequoia*). *Pseudotsuga taxifolia* and *Pinus Lambertiana* occasionally attain 300 feet. A number of other conifers, chiefly American, grow to a height of 150 to 300 feet. Some deciduous trees, as *Platanus occidentalis*, several species of oak and *Liriodendron Tulipifera* exceed 150 feet in height. The jequitiba of southern Brazil (*Couratari legalis*, one of the Myrtaceæ) is also a gigantic tree (see Bot. Gaz. 31, p. 352).

The greatest diameter has been observed in *Castanea vesca*, of which a tree with a partly decayed trunk at the foot of Mt. Etna in Sicily measures more than 60 feet in diameter. After this the greatest diameter observed is in *Taxodium mucronatum*, about 40 feet, and in *Platanus orientalis* about the same, in *Sequoia gigantea* 35 feet, in *Taxodium distichum* 30 feet, and somewhat less in *Adansonia digitata*.

The age attributed to many of the tallest trees is based more or less on speculation, and opinions often differ widely. *Dracena Drac* is believed to reach 6,000 years of age, *Adansonia digitata* 5,000, *Taxodium mucronatum* and *Platanus orientalis* 4,000, *Cupressus sempervirens* and *Taxus baccata* 3,000, *Castanea sativa*, *Quercus pedunculata*, *Sequoia gigantea* and *Cedrus Libani* more than 2,000 years.

Although the trees are the most conspicuous features of the vegetable kingdom, they represent only a small percentage of it as regards the number of species. In the United States, where about 600 trees occur, they represent only about 3½ per cent of the whole phanerogamic flora, in Europe even less. As a rule, towards the tropics the number of tree-like species increases, towards the arctic regions it decreases. Remarkably rich in trees is the flora of Japan, where the proportion of trees to the whole phanerogamic flora is more than 10 per cent, which percentage surpasses by far that of any other country in the temperate regions.

Trees belong to many different natural orders, but of the orders of monocotyledonous plants only a few contain trees and none of them is hardy North. None of the larger orders contains trees only, but there are some which consist exclusively of woody plants and include a large proportion of trees, as Pinaceæ, Fagaceæ, Salicaceæ, Juglandaceæ, Magnoliaceæ, Sapindaceæ, Elæagnaceæ, Ulmaceæ, Hamamelidaceæ, Lauraceæ, Anacardiaceæ, Ebenaceæ, Styracaceæ and others.

The uses of trees are manifold, and a country from which the forests have been destroyed becomes almost uninhabitable and worthless to mankind. The forests furnish wood and timber, exercise beneficial influences on the climate, act as regulators of the waterflow, prevent erosion and also the removal of soil by the wind. Besides furnishing wood and timber, many trees yield other products of great economic importance, especially the numerous kinds bearing fruits. The æsthetic value also of the tree must not be underrated, although it cannot be counted in money.

The science of trees and shrubs is *dendrology*. The art of growing trees is arboriculture, while the rearing and maintaining of forests and the production of timber-crops is silviculture. Arboriculture is sometimes used in a broader sense, like dendrology, to include also the growing of shrubs. Orchard culture is a branch of arboriculture or of horticulture, and deals with the cultivation of fruit trees; it is usually included under pomology, which comprises both the science and practice of fruit-growing.

As ornamental subjects, trees are more permanent, easier of cultivation and cheaper in the long run than herbs. It is curious to note how little attention the average gardener who has the care of a park or garden gives to the most prominent feature of his domain. He

IX. Arboretum.—Plantation of American oaks at the Arnold Arboretum: *Solidago canadensis* underplanting.

usually knows fairly well the greenhouse plants and herbaceous perennials, which cost most in time and money, but the trees and shrubs he often disregards. This is apparently due to the fact that after being once planted, and often not by himself, the trees and shrubs do not need his perpetual care, and usually grow without his aid and interference.

To the landscape gardener a thorough knowledge of trees is absolutely essential. He ought to know the ornamental properties of the trees, their rate and mode of growth, their peculiarities in regard to soil, situation and climate. As the trees are, after the surface of the ground, the most permanent element of the landscape, they ought to be planted with careful deliberation as to the intended artistic effect and their fitness to the soil and climatic conditions, for mistakes in planting of trees are afterwards not easily corrected and rarely without injury to the original artistic design. The available number of trees from which selection may be made is large. There are in American and European nurseries and gardens more than 600 species in cultivation that are hardy in the northern and middle states. About 250 of them are American, more than 200 from eastern Asia, about 100 from Europe and 70 from western and central Asia. About forty natural families are represented, of which the most important are the Pinaceæ, Fagaceæ, Salicaceæ, Rosaceæ, Leguminosæ, Juglandaceæ, Sapindaceæ, Urticaceæ, Magnoliaceæ, and Oleaceæ. The number of all the cultivated varieties and garden forms is, of course, considerably larger than that of the botanical species and may be estimated at about 3,000. Comparatively few horticultural varieties are found in American nurseries as compared with European, but this need not be regretted, as horticultural varieties are mostly merely curious or monstrous forms. In planting, one must rely chiefly on the types and use the horticultural varieties sparingly, for restfulness should be the prevailing character of the masses and groups of trees.

#### The cultivation of trees.

From earliest times man's instinct has been to seek the protection of trees. In locating his home the first necessity has been the proximity of water; second, pasture for his flocks; third, the presence of trees; in warm countries it has been necessary to provide protection from the hot sun's rays, in cool countries for the sake of fuel and protection from the elements. As civilization has progressed and man has developed more elaborate abodes, he still desires the protection of trees to make his home more comfortable, to protect it from the winter wind, or the summer sun, or both.

To meet the needs in different localities, as one or another protection may be more important, different kinds of trees are used. In the extreme North, the coniferous evergreens act as windbreaks twelve months in the year. In the south Atlantic and Gulf regions, the broad-leaved evergreens give shade the year through.

In the intermediate country and overlapping both, the deciduous trees afford much summer protection and a little winter protection. The chief æsthetic value of trees is due to the suggestion of comfort that they give. In winter, a house snuggling against a group of evergreens may be attractive, and yet, if lacking a well-placed shade tree, may in summer appear glaring or otherwise uninviting. These feelings are the same with regard to native woodlands or man-made clumps more remote from dwellings. The different kinds of forest attract because of suggestions of comparative comfort and of pleasures. To those who have lived in the heart of a large city all their lives, such scenes are likely to be unattractive because of lack of suggestiveness. Some of the interesting and varied forms of trees are displayed in Figs. 312 to 359.

In planting trees for ornament, these elements of pro-

312. A group of old sugar maples, with irregular and broken heads.

tection suggest two uses, that of windbreaks and that of producing shade at appropriate places. In addition are the partial hiding of buildings from important viewpoints, enhancing the beauties of the building or permitting only the most desirable features to be seen, covering the outlines of ugly buildings, or completely hiding objectionable objects, either nearby or distant; forming frames for distant views or nearby objects; making knolls and hills look higher by groves on their tops, or valleys look deeper because of wooded sides; making irregular sky lines either by accentuating existing conditions by planting tall trees on the high places and low trees in the low places, or in level countries making a similar sky line by tall and short trees; or forming irregular and natural appearing boundaries to lawns or meadows.

To accomplish any of these results, some trees are inherently better suited than others; climate and soil, however, may make their use impracticable or impossible. Coniferous evergreens make the ideal windbreak and screen, but they are satisfactory only in the north-eastern section of the country and on the Pacific Coast, the hot sun of the South, the dry winds of the central plains and the smoke of cities making most species impossible in those regions. The broad-leaved evergreens are next in importance, but they are adapted only to the south Atlantic and Gulf seaboard, and the Pacific Coast north of San Francisco. For adaptabilities see special lists, for no other sweeping generalizations of adaptabilities can be made except that the use of bronze, yellow or variegated-leaved trees, and trees of unusual drooping habit or of other striking form, should be limited to special times and places. A tree to be satisfactory for ornamental planting must suit the

climate and maintain the appearance of healthy growth on the soil where planted, must be hardy, and must be free from serious insect and fungus attacks.

The location of trees is a detail of the design of the place. This is intimated in the preceding paragraphs and more fully discussed under Landscape Gardening, but a few cautions may be in order. Do not so surround the house with trees that they exclude all the sunshine. Except in the extreme South, use deciduous trees next the house so as to have full benefit of the winter sun. Plant the evergreens at a little distance. For specimen trees of the larger kinds, plant 50 to 100 feet apart, depending on the kind. For thickets and quick masses of foliage, the same kinds may be planted 15 feet apart. Theoretically, planting more trees than are ultimately necessary and then thinning is excellent. Practically, it is dangerous as there is not one chance in ten that it will be done in time. Plant irregularly both as to distance and direction unless the design is strictly formal, in which case plant with mathematical precision.

#### *When and how to plant.*

There is great difference of opinion as to the best time to plant. In climates with the temperatures of Boston, Rochester, Chicago and farther north, spring planting is probably best for most plants. Fall planting is increasingly more satisfactory as one goes south. On the western plains where strong, dry winter winds prevail and the soil is either so dry or freezes so hard that a newly planted tree cannot replenish the moisture taken out by the winds, spring planting is most successful. The character of soil may also have its influence. Magnolias and tulip trees should always be planted in spring. Coniferous evergreens should be

313. A commanding white oak on a bank margin.

planted either when growth has started in spring or, when vigorous, in late summer or early fall. Other evergreens should be planted when entering the period of most active growth so as to be able to form roots quickly to support the foliage that is always present. The period of generous moisture in air and soil is most favorable for the planting of evergreens. In adverse seasons, these conditions may be in a measure produced by liberal watering of the soil and frequent spraying of the tops. Deciduous trees should be planted

when dormant, in order that roots may become well formed before there is foliage to support.

Large holes should be prepared for planting, at least 2 feet larger in diameter than the spread of the roots of the lifted tree, and 2 feet deep. If the soil is good, no further special preparation is necessary beyond a liberal mixture of well-rotted manure or raw bone-meal with the soil to be replaced in the hole, and supplying new topsoil to replace any subsoil excavated in digging the hole. In poor ground, a hole at least 6 feet across and 2 feet deep should be dug for a tree up to 8 feet high, and for larger trees proportionately larger holes to give them good ground for beginning growth. It is becoming common to dynamite holes for trees. Just how far this is desirable is yet problematical. In tough subsoils, it appears to be eminently successful. It seems reasonable to suppose that in most subsoils such a loosening would be permanently beneficial. Careful observers have noticed that trees usually thrive better on filled ground than on nearby soil where the land has been undisturbed, even though the fill appears poor in comparison. This does not have reference to city ash and garbage dumps. The ashes are too inert to support tree growth, the dump is frequently poisonous. In large plantings, the watering of deciduous trees and the staking of trees under 10 feet is usually omitted in the moist regions in which strong winds do not prevail, the replacing of any losses being considered more economical than this additional expense. Larger trees need special attention.

The size of trees to choose varies with the kind, the purpose, and the need for quick results. Trees may be successfully transplanted from one- or two-year-old seedlings to those 12 or 16 inches through and 40 feet high, success depending largely on the skill of the planter. Usually trees 6 to 12 feet high are best for deciduous trees, 3 to 6 for coniferous. Some species succeed better with small sizes, as tulip tree, magnolias and hollies. Nursery-grown trees that have been frequently transplanted are best, as they transplant with less loss because they have an abundance of fibrous roots. Collected stock of some kinds is satisfactory for mass-planting but the loss will run from 50 to 90 per cent, depending on kind and condition. Trees that are very small are not desirable to use, as they grow no better than larger nursery-grown trees and the cost of cultivation is more when planted permanently than when in the nursery row. Trees above the sizes mentioned are expensive to handle and the loss is likely to be greater. When immediate results are important, these are worth using with a mixture of smaller trees to take their place in case they should be short-lived.

#### *Pruning and tree-doctoring.*

At planting, all broken limbs should be removed as well as any crossing through the head or below it. If the top is still crowded, some limbs may be removed by cutting them off at the nearest fork. Heading-in or shortening the limbs is undesirable with most species. The magnolias and tulip tree are exceptions to this; they need severe shortening-in when transplanted. All roots should have the broken ends cut off with a smooth, clean cut, as this freshly cut surface seems to facilitate the formation of new rootlets or at least to prevent decay. If a newly planted tree is very slow in starting, it is sometimes induced to grow by a severe pruning.

Desirable varieties of shade trees seldom need any heading back. An annual inspection with slight pruning to shape the tree and remove surplus branches is all that will be required. A tree should be grown into shape, not pruned into shape, and should be allowed to develop its own characteristics.

Evergreen trees, with the exception of the evergreen oaks and *Magnolia grandiflora*, should be trained so that their foliage rises directly from the turf. As it

grows old, the white pine is likely to bare its trunk in spite of other training. Spruces and other coniferous trees are ruined if pruned to show the trunk. Figs. 318, 319. Many deciduous trees are also most attractive when their lower limbs rest on the ground, as beeches, the Norway maples, hornbeams and many more, any tree in fact whose natural habit will permit such a form.

Old trees, owing to neglect, or more often, improper pruning, frequently need the saw. Protruding stubs should never be left, whether the tree is large or small. The cut should always be made close to the remaining limb and parallel with it. It will not require over two years for the callus to show all around a properly made cut. If it does not show then, the work should be done over again. All dead wood should be kept out. Crossing limbs, even if large, should be removed. A tree should not be dehorned, i.e., cut back to stubs 3 or 4 inches or more in diameter, except as a last resort for a failing tree.

Pruning is employed for two distinct ends: to train and shape a young tree as it grows; and to re-form or adapt a tree of some maturity, especially if somewhat decrepit. The so-called "tree-doctoring" or "tree-surgery" is applied especially to the latter phase. A tree that has become weakened by transplanting, or from lack of proper nutrition, from lack of proper fertility, or scarcity of water, or from other undetermined causes, may often be forced into active vigorous growth by a severe cutting-back. It may even be allowable, in such cases, to pole or dehorn a tree; that is to remove most of the small limbs, cutting the large ones so close to the tree as to leave stubs as large as one's wrist or arm or even larger. It never happens that several trees in a row need such treatment unless their feeding-ground has been greatly depleted.

Trees that have been badly pruned, broken by wind, storms or otherwise bruised or mistreated, frequently have badly decayed spots in their trunks and limbs. It has become the custom to "doctor" such trees,—that is, thoroughly to clean out rotten wood, treat the exposed surface with a solution of corrosive sublimate or sulfate of copper to kill any fungous growth that may be present, with bisulfide of carbon or other insecticide for insects, and then coat the surface with tar as a preservative. After this the cavity is carefully filled with concrete of the strength commonly used in construction work. It is absolutely essential to success that the joint between the wood and cement be water-tight. The surface should also be given a smooth finish of the general outline that the tree would assume had it grown normally. The finished surface should coincide with the inner edge of the cambium layer so that the growth of the tree will proceed over the cement just as it would over a properly cut stub. Zinc caps are frequently used both to cover cement fillings to keep out the water and to cover large cuts when the wood is solid but when it will take several years to heal on account of the size of the wound. Cavities must be absolutely clean, thoroughly disinfected, and the filling positively water-tight or decay will begin behind the filling and the tree will be destroyed while every confidence is being felt that it is safe. The cement work is frequently reinforced with rods of iron. Its principal value is to hold the cement from cracking. The only value of such cement work is as a preventive of decay where there are cavities. When properly done, it gives a smooth surface over which the growth may proceed. The supporting value of the cement to the tree is slight.

With many hardwood trees in important locations such treatment is warranted, but at the present time many trees are thus treated that should be cut down, while many others are left that should have attention. The first requisite to warrant the treatment of a large cavity is a good type of tree in an important location, for example a large tree protecting the home from the

mid-afternoon sun, or a bad individual in an avenue of otherwise good specimens. In large plantations, treatment of a preventive nature is of course warranted, but the filling of large cavities is not worth the cost except to those to whom money is little object. It is better to start new trees than to spend fifty dollars on patching up an old one. One must exercise careful judgment in selecting old trees for treatment, to make sure that the tree is worth it. Trees worth doing work on are the oaks, sugar, swamp and Norway maples, hickory, ash, elm and the slow-growing native trees. Those not worth treating in this way are the poplars, willows, silver- and ash-leaved maple and sycamore or plane

314. Picturesque old apple trees.

tree. A street tree with a large cavity would better not be doctored unless it is of special value and of a kind likely to last a long time.

Badly branched trees often show a tendency to split in the crotches. It is well to attend these trees before they begin to split and either chain or bolt the offending limbs together. They may be chained by putting lag-screws in the limbs, drawing the limbs together and dropping a link of the chain over the turned up end of the screw. Rods and turn-buckles may be used in the same way, the bolts for the rods being put through the limbs, not around them. Because bolts have to be placed closer to the weak point than the other remedies, they are not so effective but are often useful. If a tree splits, there is danger of decay. The splitting should be anticipated and prevented whenever possible.

The best time for pruning is not a question of invariable rule. The period of most active growth, in most places June, is usually regarded as the best time. The period of starting into leaf is probably the worst time, although the maples are about the only good shade trees that seem much affected by pruning at this season.

Large cuts or wounds should be immediately painted with a good grade of paint or with tar, care being taken to cover the exposed wood but not to allow the paint to come into contact with the cambium layer, or growing part of the bark.

Root injuries should be as zealously guarded against as injuries to the top. If a large part of the roots must be removed, the top should be correspondingly thinned. Changes of grade are a great source of damage to shade-trees, even when the roots are not actually touched. The filling of 2 or 3 feet of soil over the roots of a tree is, for most varieties, as sure death to the roots as cutting them off close to the trunk. This filling prevents the aëration of the soil and smothers the soil life on which healthy root-action seems to depend. This may be

prevented by a good layer of loose stones, open at intervals to the air, placed over the surface before filling, or, in some cases, by the use of agricultural tile drains on the old surface at close intervals and so arranged as to facilitate a free circulation of fresh air through the tiles.

#### *Street trees.*

In the development of towns and cities, the need of trees as a protection against wind has been reduced to a minimum since the closely built houses protect one another. This close building, however, has brought about another untoward condition that needs ameliorating; this is the replacing of the vast extent of green, common to the open country, by a motley array of discordant colors. Many of these colors have been demonstrated experimentally and practically to have exciting and debilitating effects on the physical condition of persons. Part of the great utility of parks is to afford urban residents relief from this color excitement. As far as possible, the soothing green needs to be

315. A group of surviving hemlock spruces.

taken into the city streets to rest the tired nerves through the effect on the eye. Also, the shade helps to reduce the temperature by absorbing the sun's rays; the large amounts of water the tree transpires also helps to cool the air. These beneficial effects make it worth while to expend effort and money to secure well-shaded streets. Figs. 323, 324.

The conditions in urban communities are adverse to tree growth. Streets are narrow and the trees crowded; roadway and sidewalk are paved with impervious materials preventing both water and air getting into the soil, and effectually keeping in sewer-gas and illuminating-gas that may be discharged into it from below. The air is dust-laden from constant traffic, and, what is far worse, contaminated by soot and poisonous compounds from numberless badly-fired chimneys. As though this were not enough, there are the self-styled tree-trimmers, knowing nothing of the work, then the linemen cutting ruthlessly, caring nothing for the tree, and with an occasional gnawing horse adding its dem-

olition. And the sewer-layer, pipe- or conduit-layer and finally the curb-setter do their worst. After all of these, come the insects and diseases that affect trees everywhere and which here find an easy prey because of the fewer birds in city streets and the weakened condition of the trees.

The first essential to successful street tree-planting is competent municipal control of all such work. The street trees should be under the care of an unpaid commission of three or five men, one named every two years by a local court, or by the mayor, for a term of six or ten years, and confirmed by the legislative body. Such commissioners usually need to be trained, and therefore they should have considerable experience in their work before coming into full responsibility. The restrictions on the appointment of the executive officer should be stringent, so that only thoroughly trained and experienced men could be employed. The expert should have the full confidence of the commission and be the leader in the work. To fill such a position, a man should have thorough knowledge of trees and the soils and conditions under which they grow, their characteristics, æsthetic values and habits of growth under city conditions, the methods of aiding trees to withstand these conditions, and a knowledge of the insects and diseases to which the different species are liable and the methods of combating them. The work is neither forestry nor pomology, as it has nothing whatever to do with the products of tree growth or the growing of trees for their fruits.

Powers vital to the success of this commission are the right to plant suitable kinds of trees in a proper way, and to collect benefits for work so done; to control absolutely all pruning, removal and care of trees; and the right to invade private grounds for the control of insects and diseases. Of course, sufficient funds must be available to support the work.

Many city streets are too narrow from building-line to building-line for satisfactory planting. There is absolutely no excuse for this in the newer sections. There should be at least 100 feet from building-line to building-line on any street and on principal streets considerably more. Forty feet may be all that is needed for roadway and sidewalks, at present. The abutting dwellers need the air-space provided by the remaining area which is legitimately used as front lawns. This will leave ample space for trees. If the city grows and more space is needed for traffic, it can be secured with no sacrifice to buildings and the dwellers in the interval have had better living conditions. It is this arrangement that makes Washington such a beautiful city, and the lack of it on Fifth Avenue that is costing New York City so much money to widen that thoroughfare. In the older parts of cities, species must be chosen that are appropriate to the width of the street. Most kinds should be planted not closer than 40 feet apart and such varieties as oaks, elms and sycamores would be better at 50 feet. Most planters use 35 and 40 feet because of the public demand for quick shade, and at the greater distances the trees look far apart when first planted. Theoretically, the planting double the number of trees needed at maturity or the placing of fillers of a quick-growing inferior type, is desirable; but practically it is dangerous, as there are not many cases in which public opinion will tolerate the thinning at the proper time. In city work an excavation 2 feet deep, with the removal of at least 2 cubic yards of dirt, should be made for each tree. This should be filled with good top-soil mixed with well-decomposed manure. Of most varieties, trees 10 to 12 feet high and 1½ to 2 inches caliper should be used. These should be nursery-grown. They should have been frequently transplanted and have a well-developed head, 6 to 8 feet from the ground. The roots should be abundant and fibrous. In planting, the roots should be spread out and separated to their full length, the ground worked all in amongst them, and then thor-

oughly firmed by tramping. Before the hole is completely filled, the tree should be well watered and the remainder of the soil put in loosely. A strong stake 8 feet long should be placed beside the tree when planted. At least 30 inches of this should be in the ground. The tree may be attached to the stake by a piece of old garden hose attached to each side of the stake and put around the tree in such a manner as to make a cross between the stake and the tree.

All young trees should be protected by boxes or guards. Many forms are used. Any of them are good if the box reaches from the ground to a height of 5 feet and will prevent horses biting the trunks and boys swinging on the guard.

#### Notes on ornamental trees.

*Acer Negundo* (box elder). Too short-lived, brittle and subject to insect attack. Its use may be warranted in semi-arid and very cold regions.

*Acer platanoides* (Norway maple). Moderate grower, healthy, but too dense for close city streets.

*Acer rubrum* (swamp maple, scarlet maple). A good-sized tree, good grower, fine foliage, especially brilliant in autumn. Also a bright red in spring due to blossoms and young leaves. Not suited to the interior of large cities.

*Acer saccharinum* (silver maple, soft maple). Rapid grower, but too brittle and short-lived, and the shallow roots prevent the growth of grass under it and also destroy sidewalks.

*Acer saccharum* (sugar maple). Does not thrive on heavy clay soils or under severe city conditions but most excellent where it does grow. Moderate grower, doing best north of the 40th parallel.

*Ailanthus altissima* (ailanthus, tree of heaven). A large, handsome tree, the staminate and pistillate flowers appearing on different trees, the latter very ill-smelling. A most useful tree in the center of large cities. The staminate form only should be planted.

*Celtis mississippiensis* (southern hackberry). An excellent tree in those regions in which the "witches-broom" does not attack it. One of the promising trees to withstand the hot winds of the plains as far north as Denver. A large tree and good grower.

*Celtis occidentalis* (hackberry). A good tree where the disease known as "witches' broom" does not attack it. It is for regions north of the 36th parallel what the foregoing species is for the region south of it.

*Frazinus americana* (ash, white ash). A good tree for suburban conditions. Moderate grower, attaining large size.

*Ginkgo biloba* (ginkgo, maidenhair tree). An excellent tree of peculiar pyramidal form when young. Moderate grower, attains good size and is free from insect and fungus attacks.

*Gleditsia triacanthos* (honey locust). A large, quick-growing, handsome tree. Except for its thorns, this tree would probably be a most desirable tree for the semi-arid regions of the West. There is a thornless form that may sometimes be obtained, which is good

316. *Pinus ponderosa*.  
Giant specimens 225 ft. high, grown in the deep, moist soil of the Yosemite Valley.

*Liquidambar styraciflua* (sweet gum). A handsome and valuable native tree but little used. Moderate grower, good size, handsome fall coloring. A little hard to transplant, especially in large sizes. Does not succeed well under extreme city conditions, and is not adapted to the extreme northern sections.

*Liriodendron tulipifera* (tulip tree). Miscalled yellow poplar, and tulip poplar. A handsome, large, quick-growing tree, little used, but valuable except for extreme city conditions and much of the country north of the 40th parallel. A little hard to transplant, especially in large sizes, and should be moved only in spring.

*Magnolia grandiflora*. A broad-leaved evergreen of large size, adapted to the extreme South. A good lawn tree as far north as Washington.

*Magnolia acuminata* (cucumber tree). A handsome tree of moderate size, good for suburban conditions south of Washington and St. Louis.

*Magnolia tripetala* (umbrella tree). A handsome tree of moderate size, good for suburban conditions south of Washington, and St. Louis.

*Melia azedarach* (umbrella tree). A small, attractive tree, good for temporary effects from North Carolina south and west.

*Nyssa sylvatica* (sour gum, tupelo). A large, handsome tree, adapted to suburban conditions. Brilliant fall foliage and winter berries.

*Platanus occidentalis* (sycamore, buttonwood). A large tree, rapid-growing, open-topped, and almost scraggly in its growth. Considered an untidy tree by some on account of its seed-balls and the bark which is shed in large flakes. The white trunk, after the bark is shed, is unusual and attractive. In some regions it is subject to a blight just after the leaves start in spring. A good tree for severe city conditions.

*Platanus orientalis* (plane tree, oriental plane). A more compact grower than the foregoing and a little better suited to street purposes, but not quite so rugged and imposing as the foregoing. An excellent street tree.

*Populus deltoides*, including var. *caroliniana* (cottonwood and Carolina poplar). These two trees are much used for street planting in many places but are entirely unsuited for the purpose. Although the growth of a severely pruned tree is large in any one year, it is the custom to remove a half of this each year so that the net gain in growth is no more than an average tree. Even with this pruning it is liable to be broken by a moderate wind storm, and without the pruning it is even more liable to be broken. Their roots are as bad as willow roots about finding and clogging sewers. Wide-awake cities prohibit the planting of these trees.

*Populus nigra* var. *italica* (Lombardy poplar). A tall, short-lived, fastigiate

317. Conifer forms — Pine and spruces.

tree, suitable for narrow streets in the heart of a large city.

*Quercus alba* (white oak). A most picturesque tree, attaining the largest size. The gem of American trees, and not so slow-growing as usually considered. Dead leaves hang on most of the winter. Figs. 313, 322.

*Quercus bicolor* (swamp white oak). A large, handsome oak of moderately rapid growth, suited to moist situations. It seems to succeed under city conditions. A desirable shade tree, almost as handsome as the white oak and a little faster grower.

*Quercus coccinea* (scarlet oak). Comparable to the red oak but not quite so sturdy and vigorous under all conditions, but with a little more brilliant autumn coloring and leaves more finely cut.

*Quercus laurifolia* (laurel oak, water oak). The standard street tree for the South. A large, handsome, deciduous tree, not so desirable as the live oak, but of more rapid growth.

*Quercus Michauxii* (cow oak). A good oak for thin gravelly lands. Not so desirable as the other oaks on

318. Spanish Fir.—*Abies Pinsapo*, showing the verdure from top to base.

good ground and not adapted to the extreme northern sections.

*Quercus macrocarpa* (mossy-cup oak). A handsome and satisfactory tree, not so large as some of the others. One of the most promising for the plains.

*Quercus nigra* (possum oak, water oak). Another good oak south of Norfolk. A little more upright in growth than *Q. laurifolia*, but not quite so desirable except possibly in its more northern limits.

*Quercus palustris* (pin oak). A quick-growing, good-sized tree, with pendulous branches when old. Handsome cut leaves, brilliant in autumn. One of the best. Its pendulous branches may sometimes be a rather serious objection. Dead leaves hang on well into the winter. Fig. 323.

*Quercus phellos* (willow oak). A large, handsome tree, moderately fast-growing, satisfactory south of Washington in regions in which it is not attacked by a growth resembling "witches' broom" of the celtis.

*Quercus rubra* (red oak). Almost the best street tree. Large, symmetrical, rapid in growth, fine autumn foliage, head not too dense. It is exceeded only by the elm in rapidity of growth among the trees suited for street planting and not by that in the southern half of the country.

*Quercus virginiana* (live oak). A large evergreen. The best street tree for the South, but slower in growth than *Q. laurifolia*.

*Sterculia platanifolia* (varnish tree). A small tree of reasonably rapid growth bearing bright yellow flowers.

It has a tropical suggestion. Good only for the South and its principal value is in its possibilities for the Southwest, especially semi-arid Texas.

*Tilia americana* (basswood, American linden). A large, handsome, quick-growing tree. Young trees are sometimes affected by a disease at the base of the trunk, but the tree is well worth growing except in regions in which the difficulty is known to be present.

*Ulmus americana* (elm, white elm). The shade tree of New England and deservedly ranked first there. It loses its preëminence as one goes from New England, but a large, quick-growing tree worth using except in the extreme South. Drops its foliage too early to be the ideal shade tree in the middle states and southward. It is subject to the attacks of the elm-leaf beetle in regions in which that has been introduced.

F. L. MULFORD.

### The conifers in particular.

The cone-bearing trees (*Pinaceæ* and allies) are decidedly the most important order of forest trees in the economy of civilized man. They have furnished the bulk of the material of which our civilization is built. The remarkable combination of strength and stiffness with the smallest weight compatible, and the abundance and gregariousness of their occurrence, give them this important position.

From the standpoint of the horticulturist, the conifers also take a prominent place among the materials for landscape gardening effects, and, in the more practical use, as windbreaks. Their evergreen habit—for all except the larch and ginkgo tribes are evergreen—and their conical form, especially in earlier periods of life, with a branch system persisting to the base for a long time, are the elements that make them desirable. To these graces may be added the peculiar form and striking coloring of their foliage, which, in combination with deciduous trees or in clumps by themselves, or in single specimens, offer striking effects.

There are two types of natural or native beauty in the conifers—the symmetrical and verdurous beauty of the young specimen (Figs. 318, 319), and the picturesque and rugged beauty of the old and timeworn tree (Figs. 315–317). Aside from these, there are also odd, grotesque and formal cultivated varieties, as typified in the weeping spruce (Fig. 320), the columnar junipers, and the various dwarf pines and spruces.

The majority of the species belonging to this group, as well as their greatest numerical development, is found in the temperate zones, only a few belonging to subtropical or tropical countries, among which are the araucarias, from South America; the dammara, dactyidium, and phyllocladus, from Australia, and neighborhood.

### Kinds and adaptations.

The order Coniferae comprises nearly 40 genera, and about 300 species. Our own native flora, with 15 genera and not less than 100 species and subspecies, is among the richest, the bulk of these being found on the Pacific coast. The Atlantic side offers 28 species, representing the genus *Pinus* with 12 species out of 39; 1 *Larix* out of 3; 3 *Piceas* out of 7; 2 *Tsugas* out of 5; 2 *Abies* out of 12; 1 *Taxodium*; 1 *Thuja* out of 2; 1 *Chamaecyparis* out of 3; 3 *Juniperus* out of 11; 1 *Tumion* (*Torreya*) out of 2; 1 arborescent *Taxus* out of 2; being without representatives of the genus *Pseudotsuga*, *Sequoia*, *Libocedrus*, and *Cupressus*. There are to be added a large number (not less than 400) of nurserymen's varieties, some of which have been enumerated in Bulletin 17 of the Division of Forestry, United States Department of Agriculture.

There are also a number of exotic conifers that promise satisfactory results if used in suitable localities, climate and soil. The Norway spruce (*Picea ex-*

*celsa*, Fig. 356) recommends itself by its elegant gothic form, often with pendulous branchlets, its very rapid growth, and its wide adaptation to soils and climates, together with its ease of propagation and cheapness. It excels most of the American spruces in form and rapidity of growth. Like all conifers, after the twenty-fifth to fortieth year it must pass through a period of change in form, during which it loses, for a time, its shapeliness. The Scotch pine (*Pinus sylvestris*) has nothing to recommend it which may not be found in native species, except, perhaps, adaptation to the dry climate of the West, and cheapness. The Austrian pine, on the other hand, is an acquisition by its stout growth in its youth, although the red pine (*Pinus resinosa*) would probably do as well; so far, its small cones and seed have made the latter expensive. The European larch outgrows the native northern one easily, but *Larix occidentalis*, from the interior basin, will probably do as well or better. There is no particular commendation for the European fir, but the Nordmann fir, from the Caucasus, is a most decided acquisition, by its beauty and adaptation; so is the most graceful of all spruces, *Picea orientalis*, while the Spanish *Abies Pinsapo* (Fig. 318) will always attract attention by its peculiar shape and foliage.

Of other ornamental forms that are without representatives in the United States and hence fill vacancies, may be mentioned as capable of adaptation and more or less in use, from South America, the araucarias; from Africa and eastern Asia, *Cedrus Deodara*, *libani*, *atlantica*, *Abies Apollinis* and *cilicica*; from Korea, the promising, more densely foliated white pine, *P. koraiensis*; from China, *Cunninghamia*, *Biota*, *Glyptostrobus*, *Cephalotaxus*, *Podocarpus*, *Pseudolarix*, and, above all, that interesting remnant of former ages, the maiden-hair-tree, *Ginkgo biloba*, which will maintain itself anywhere along the Atlantic coast if propagated from seed of the proper localities. Japan has furnished a number of additions, especially *retinosporas*, *torreyas*, *taxus*, various *pinus*, *piceas* and *tsugas*, with the peculiar *Sciadopitys verticillata*, the umbrella pine, and, the most acceptable of all, the graceful *Cryptomeria japonica*.

As with all introductions from one country to another, nay, from one climatic region to another, caution is advised, so it may be laid down as a rule, that exotics should be used with great discretion, and, until their adaptation is amply demonstrated, only in a subordinate way. If it is in general true that perennial plants can be transplanted with permanent success only into similar climatic conditions, it must be especially true with the conifers, which do not lose their foliage, and hence must be able to bear summer as well as winter conditions. The long-leaf pine of the South, most striking of our pines, may, therefore, not be transplanted far beyond its northern limit, and, if one desires to utilize any of the Pacific coast species in the East, one will have to secure them at least from the highest and driest altitudes and exposures, or if, as in the case of some species, like the Douglas fir and Engelmann spruce, their field of distribution covers the dry slopes of the Rocky Mountains as well as the moist slopes of the coast ranges, one may be successful if one chooses the plant material from these drier slopes.

Of the many native species, a number that are not of any particular value may be discarded, although the distinction could be more readily accomplished from the economic point of view than from the standpoint of the horticulturist and landscape gardener, for almost every one has a distinctive feature of either form or adaptation to soil or other interest. For each climatic region the choice must be different; hence it would be impossible to give, in the brief space of an article, intelligent advice as to best selections. In general, besides climatic limitations, the following considerations may serve in the choice of native species:

The pines, as a rule, are not to be placed on compact clay soil, and on account of their taproot, not on shal-

low soils, on which they soon become spindly; they thrive best on loose, sandy soils, and can endure dry soils, the white pine adapting itself perhaps best to the clay soils without detriment to its development. On wet soils pines are, as a rule, decidedly out of place, although the red pine (*P. resinosa*), of the North, and the loblolly (*P. Tæda*), and some other southern species are capable of supporting such conditions. For such situations here, however, the cedar tribe furnishes better material,—the *chamæcyparis*, *thuyas* and *taxodium*. These trees of the bog and swamp are, however,—it should not be overlooked,—capable of thriving even better on drier soils. They are merely indifferent to moisture conditions at the foot.

The shallow-rooted spruces are trees of the higher mountain ranges, and are, therefore, more adapted to moist and cool situations, although some of them, the

319. A well clothed conifer.—*Abies venusta*.

Norway spruce, the blue spruce of Colorado and the northern white spruce will—the former, at least, during its juvenile period—endure more droughty situations. The firs, too, are rather more species of northern climates and high altitudes, the red fir, so-called (*Pseudotsuga taxifolia*), which is not a fir proper, being, perhaps, best capable of supporting drier and hotter situations. The most ornamental, and, in many respects, most serviceable of the firs, *Abies Nordmanniana*, from the Caucasus, develops its magnificent dense and dark green foliage in the warm but moist climate of Washington, while our most ornamental *Abies concolor* from Colorado will thrive even in the drier atmospheres of the middle states. The fine firs of the Pacific coast will probably not thrive anywhere in our drier and hotter eastern climates for any length of time, unless placed in cool and shady situations.

The Douglas fir (*Pseudotsuga taxifolia*) is, perhaps,

most readily acclimated if seed is secured from the dry slopes of Colorado. The Lawson cypress (*Chamaecyparis Lawsoniana*), with its graceful pendulous branches and foliage, and the pyramidal *Libocedrus decurrens* are unquestionably desirable additions to our ornamental stock, while the sequoias, especially *S. gigantea*, the big tree, seems not to be able to support persistently our eastern climate.

One important feature which enters into consideration when grouping conifers is the relative endurance

320. A "weeping" or drooping form of Norway spruce. This is a so-called horticultural variety, to be planted only sparingly.

of shade or tolerance which the species exhibit, thereby indicating their use in various positions. The yews and firs are the most tolerant of shade, together with the hemlocks; next may be placed the spruces, arborvitæ (*Thuja*), and junipers, while the pines are mostly intolerant of shade, excepting the white pine, which is the most shade-enduring of the pines; the larch and the bald cypress are the most light-needing of all, and will perish soon if placed under the shade of any other trees. All species, to be sure, are capable of more shade-endurance when young and on deep, moist soil. Their relative shade-endurance under the same conditions remains, however, the same, and may be studied in the forest by observing

#### Propagation.

Most conifers ripen their fruit in the fall, September to November, and are best gathered soon after or before ripening. The pines require two years (some three years) to mature their cones. White pines ripen fruit in the first two weeks of September, and the cones opening shed the seeds at once, the empty cones remaining on the branches. The cones of the firs fall apart upon ripening, hence must be gathered before being quite ripe. Spruces and hemlocks shed seeds from time to time, opening and closing their cones according to the weather through the winter into spring. Some pines, like *Pinus pungens* and *P. serotina*, keep their cones closed for years, and artificial heat must be employed to make them open and give up their seed. In gathering seeds for the trade, such artificial heat is frequently applied with pines in specially constructed seed-roasters; such seed should be carefully inspected, as it sometimes suffers from improper use of the heat.

The proportion of germinating seeds, and the vitality, i.e., the ability of retaining germinative power, varies greatly not only with the seasons in the same species, but from species to species.

The lowest germination percentage and vitality is found in firs and larch, which show rarely more than 50 per cent of good seed, and soon lose their vitality, while spruce and pine, when entirely fresh, may show as much as 95 to 100 per cent germination, and retain vitality for two to five years, losing each year a proportion. Norway spruce five years old still having 10 per cent germination.

In trade, a germination percentage for spruce of 75 to 80; pine, 70 to 75; fir, 30 to 50; larch, 20 to 40, should be acceptable.

Seeds are best kept in a dry, cool garret in tight bags or boxes, excluding the air as much as possible.

All seeds require a short rest or after-ripening of two to four weeks before they are ready to germinate, and some, like the taxus and juniper, lie over, even in nature, for a year or more before they germinate. The latter should be prepared for sowing by macerating them, and removing the pulp in hot water, then mixing with sharp sand in bags, and by friction freeing the seed from the pulp.

In the seed-bed somewhat more care is required than with most other species of trees. A thoroughly mellow, well-pulverized seed-bed of light loamy sand, possibly enriched with well-decomposed manure (cow-dung better than horse-dung) is required, the covering of the seed varying, according to size, from a mere sprinkling for larch to  $\frac{1}{4}$  inch for the heavy-seeded pines. They may be sown as soon as the weather is settled, in northern latitudes the second or third week in May, best in rows not more than 6 inches apart, and preferably in dry weather, when the soil does not clog, for clogging or baking of the earth sometimes prevents seeds from germinating. Mulch between the rows with pine needles or sphagnum moss, or other fine mulch, to reduce necessity of watering and weeding. Conifer seeds need very little water for germination. The seedlings, on the other hand, for the first three months, until they have made their crown bud, need to be either kept well watered or else protected against the drying effects of sun and wind by shading, for which purpose lath screens are best. These latter must be lifted for airing after the sun is gone, especially in muggy weather, to avoid damping-off. For wintering, a covering with conifer branches or very clean meadow hay is advisable (the latter is likely to bring in weeds).

For growing small quantities, the use of boxes, as described by Jackson Dawson, of the Arnold Arboretum, in Proceedings of the Massachusetts Horticultural Society, is highly commendable. In well-drained boxes, sow the seed soon after gathering, pile four or five deep in a pit or sheltered place, cover with boards, and when cold weather comes, cover up with leaves or hay. About the middle of April, move them into a place where they get the early morning sun. Keep the seedlings well watered and free from weeds, and shaded as described. Winter the seedlings in same manner as the seed-boxes,

321. A "weeping" tree, representing a grotesque horticultural variety.—*Ulmus scabra* var. *horizontalis*.

well covered up. They are ready for transplanting next spring, when they are making their first or second set of true leaves.

Since pine and spruce seedlings take about seven to ten pounds of phosphoric acid, ten to twenty pounds of potash and fifteen to thirty pounds of lime, besides

twenty pounds of nitrogen, per acre from the soil, for continuously used nurseries the addition of mineral materials in the shape of bone-meal and wood-ashes may become desirable.

A large number of seedlings may be grown in a small space; thus 30,000 Norway spruce may be grown on a square rod, requiring about two pounds of seed. The quantity of seed sown depends, in part, upon the length of time it is expected to leave seedlings in the seed-bed, besides size and quality of seed; the quantities vary from one-fourth to one-half pound per 100 square feet if sown in drills, and the yield of seedlings will vary from 2,000 to 25,000 seedlings, according to species and seasons.

#### *Transplanting and pruning.*

Conifers, like any other trees, may be transplanted at any time of the year, provided the necessary care is taken in moving the plant. This care is least required, as with other trees, in the fall and early spring, when activities of root and foliage are, if not at rest, at least reduced. Which of these seasons is preferable depends on the locality, and the dependent character of the season. On the whole, spring planting will probably be preferable in most parts of the United States which do not suffer from dry spring winds. In localities of the Southwest, which have commonly a dry spring followed by a rainy season in July, this latter time

322. An ideal shade tree.—White oak.

should be chosen. There is a belief that planting in August is specially favorable. There is no reason for this belief, unless favorable weather (a rainy season) follows.

Conifers may be transplanted later than deciduous trees, even after the buds have started, excepting the larch, which buds out very early; with this species, fall planting may be recommended. Cloudy weather, rather than rainy or very dry, should be chosen, especially when transplanting into nursery rows.

Young trees are naturally more readily and successfully transplanted than older ones, with which there is more difficulty in securing the whole root-system when taking them up. Since, however, the seedlings develop slowly for the first one or two to three years, they should be left in the seed-bed for that length of time, root-pruned, and then transplanted into nursery rows. Although those with a shallow root-system, like spruces and firs, may be moved even when 30 to 40 feet in height, it is best, even for ornamental purposes, not to take them more than 3 to 4 feet in height. In forestry, one- to four-year-old plants, according to species, from 2 to 12 or 15 inches in height, are preferred for reasons of economy.

Much greater care than with deciduous trees is necessary, when transplanting without an earth-ball, in keeping the root fibers from drying out; a large amount of loss in transplanting is explained from neglect in this respect. As soon as taken up, the roots should be

323. Good street trees.—Pin oaks.

immersed into a loam-puddle, or kept protected by wet sphagnum moss or canvas until set into their new place.

The question of trimming when transplanting must be considered with more care than is necessary with broad-leaved trees, which possess much greater recuperative power. It should be confined to the smallest amount, smoothing bruised roots, and if for proper proportioning pruning at the top becomes absolutely necessary, shortening the leader rather than branches. Larch will stand more severe pruning than most other conifers. From the artistic as well as physiological point of view, it is barbarism to remove the lower branches, which the tree needs to shade its trunk and standing room, and often, when deprived of the same, will replace first before starting again, in its height growth. Attention should, however, be especially paid to preventing double leaders, which are detrimental to future form-development; cut them out as early as possible, preferably in the bud. Laterals may be somewhat shortened in while standing in the nursery, to lengthen the time during which the lower branches are to persist. Breaking out buds is, as with all trees, the best method, provided the pruner has an eye for his business. Even in after-life, when pruning is performed to keep the tree shapely, the minimum use of the pruning-knife should be the rule.

There are three marked periods in the development of conifers—the juvenile period, when the entire tree is a crown, branched symmetrically to the base, the perfection of symmetry; then follows the adolescent stage, when the lower branches die out, a period of unshapeliness; followed by the virile stage, when the straight, cylindrical shaft bears the crown at one-third or one-half of the upper length of the bole. The trimming during the adolescent stage requires most consideration. It is, in most cases, best to take off only the lowest, dying or dead branches, as it becomes necessary.

In pruning, cut as closely as possible to the trunk,

324. Effect of trees on city street compared with no trees.

even cutting into the bark, also removing the swelled portion on which the branches are usually inserted, when the callousing will be more rapid and satisfactory in shape.

325. Trimmed by linemen.

preserving a dense interior foliage, while the pines are bound to thin out.

#### Enemies.

There are a number of dangers and damage from insects to which conifers are exposed. Drought and frost are most dangerous to seedlings in the seed-bed. These are obviated by proper location of the seed-bed (protection against sun and wind), by covering with a mulch of moss, straw, pine-straw or the like (which also prevents the heaving out by frost and the washing out by rain, to which young seedlings are liable). By shading and watering the danger of drought is overcome, although at the same time that of damping-off is invited. The cause of this disease, consisting in the reddening of the

needles and their falling off, is a fungus which can be combated by spraying. Birds may be kept away from the seeds by mixing them with red oxide of lead, by lath screens, and the usual methods.

Various fungi and insects, too many to mention, some polyphagous, others more or less specific, are at work during the various stages of development. A host of leaf-miners, sawflies and caterpillars destroy the foliage, and weevils sap the young shoots. *Bos-trichi*, or bark-beetles, mine under the bark, mostly of trees that are sickly from other causes; borers

enter the wood of the boles. Tortrices bore into the base of leaders and cause them to break off. The best remedies against most of these are preventives, namely providing the trees with such chances of vigorous growth, or satisfactory soil conditions, that they are able to ward off or overcome the enemies. Otherwise, watching and destroying the enemies in time, and the usual remedies to kill them, may be employed. Literature: Veitch, "Manual of Conifers;" Carrière, "Traité des Conifères;" Beissner, "Handbuch der Nadelholzkunde;" Fernow, "Care of Trees."

#### Transplanting large trees (Figs. 328-332).

Moving large trees divides itself into two classes: First, with a ball of earth; second, with the earth dissected out from the roots with or without a ball remaining in the center.

Start at or near the ends of the roots where they are 1 inch in diameter or less. In practice, this results in about 30 feet spread of roots on a tree 12 to 15 inches in diameter. An elm 18 inches in diameter on very thin gravelly soil was found to have a root 6 inches in diameter at 15 feet from the trunk, extending toward a horse-shed and cultivated field where it would get more food and water. A trench is dug to below the roots, which may be  $1\frac{1}{2}$  or 3 feet. An under-cut is made and the soil caved down by a picking bar or fork with round pointed tines. The earth and roots will be mixed at the bottom of the trench. The roots must be carefully picked up with the fingers, bound in bundles and tied out of the way. This operation is the point of greatest failure as it takes considerable time, patience and skill, to avoid breaking the roots. There are many chances to break a root after it has been carefully dissected out. The roots must be promptly lifted up or they will be broken by the shovel in digging out the loose soil at the bottom of the trench. The bundles must be untied and rearranged where the roots cross. This proceeds until a tree is dug in to a ball about 6 to 8 feet. The tree is then tipped over by tackle, cleaving the roots from the subsoil.

The amount of earth left in the center depends upon the strength of the truck, character of the roads and power for

326. Showing need of city control. This tree on a city street being trimmed for firewood.

328. Moving a tree in winter, with a large ball of frozen earth.

hauling. To leave a mass of earth 6 to 7 feet wide, 15 inches deep, is practicable with two teams and 6-inch tires over hard dirt roads. Such a ball is helpful because there are more roots left undisturbed and they help support the tree during the first summer, especially if the ball is kept to the proper degree of moisture. Larger balls, 8 and 10 feet in diameter, 15 to 20 inches deep, can be carried only by more expensive trucks with much wider wheels, and with deciduous trees the advantage is slight as compared with carrying a full circle of roots 30 to 40 feet wide.

The trees are readily picked up by the trunk which is protected by cushions and clasped by slats, and chains tightened by screws. A cradle is hinged at the front axle and tips the tree over in a horizontal position which is necessary on account of overhead wires and bridges. There are one or two screws about 9 feet long, 2½ inches in diameter. Tipping is accomplished by these screws or tackle or both. The roots on the lower side of the tree are tied back underneath the axle.

In transporting, the roots are wrapped in straw and burlap. They can be exposed to the air for a day without serious injury, as roots ½ inch in diameter do not get dried out and killed in that time. In passing under wires, these can be lifted by a T-shaped pole and disentangled from the branches by proceeding a few feet at a time. Dangerous high tension electric wires must be handled by linemen employed by the electrical company. It is sometimes necessary to raise the wires or take them down and drive over them.

In planting, the truck is drawn into the hole and stopped at such a distance from the center that the tree when swung over will be in the right position. The holes should be made of such a depth as to keep the roots as near the surface as possible. Allowance must be made for the bending of the downward roots below the center of the ball. The most frequent mistake is to get the tree too deep, especially the roots at the outside of the ball, which will often drop to the bottom of the hole and be 18 inches deep; whereas when dug there were some at the surface, some 6 inches deep and a few 18 inches deep. After the tree is stood up in the hole by means of the tackle and screws, earth is packed under the center by packing - sticks. This is difficult and there are liable to be air-holes left vacant. A stream from a hose will help to wash mud into these spaces. It is best to leave the bundles of side roots tied up while this is going on. Before the bundles of side roots are untied, the bottom of the hole should be filled up, if necessary, so that these are 2 to 8 inches below the surface. Spread out the side roots and cover with earth.

Anchoring the tree is important. It is easily done by three or four anchor posts 4 feet deep with a crosspiece 3 feet long. Wires should be put through rubber hose and twisted around the tree. The tree is liable to settle,

the anchor posts move, the tree lean and require straightening and tightening of the wires by further twisting.

Pruning is important, made so by cutting back the tree from 2 to 8 feet all around. It is best to cut the most at the apex and the least at the sides, to make the shade as wide as possible. If cut back to an even outline, the tree will make a dense growth and look more solid the first year. If the thinning-out method is used, the thinning is liable to be too great in the center of the tree, as it is easy to reach, and the tree has to thicken up over

a period of four years by making sprouts in the center, the outer branches remaining thin, especially if the tree is not fed and watered enough.

Wrapping the trunk with straw may be necessary with thin-barked trees, especially in warm and dry climates. The bark is liable to dry out and die on the southwest side. The wrapping

and anchors may be removed after two years or more.

A mistake is often made in choosing trees within two miles, whereas, the area to draw upon is over fifteen or twenty miles radius which will contain much better trees, the time on the road being a comparatively small item in the total cost. Trees are often chosen which are growing on thin or rocky soil or in swamps saturated within 6 inches of the surface, both giving much less amount of roots than trees in a friable soil 3 feet deep. In a country of hills and valleys, the best trees may often be found in terraces or benches above the river bottom or in the river bottom if drained to allow roots to be 3 feet deep. Trees are often chosen which are too old and have made a short, slow growth. It is better to move a young tree 35 feet high, 12 inches in diameter, which is growing 1 foot a year, than to take a tree the same size, twice as old, growing 3 inches a year. The roots on the latter will be longer and less flexible. Each will live and grow rapidly if given favorable conditions. A mistake is often made in choosing trees which are crowded or in thick forests. The latter may appear to have low branches. These branches are weak and liable to die. Trees of species difficult to move and

trees about the moving of which little is known are liable to be chosen. Trees which move readily are those of soft wood, rapid growth, usually native in moist soils, as maple, elm, linden, poplar, locust, catalpa, horse-chestnut, birch, apple and pin oak. The following are trees about which less is known: Pepperidge, sassafras, plane, chestnut, beech, tulip, white oak, black oak, liquidambar, ailanthus, hickory, walnut and ash. The chestnut,

beech, magnolia, tulip tree, black oak and walnut do not indicate by their behavior when small that they are readily moved. It is to be presumed that the ailanthus and ash are easily moved. No species has proved itself impossible to move. It is merely a matter of getting the right proportion of roots and top and nursing the tree through the convalescence until it has reestablished itself. In moving trees it may be better to move three

329. A large tree removed from its place. The roots are now to be wound in burlap or other material.

330. The roots wrapped, and the tree being moved on skids.

trees 8 inches in diameter, 35 feet high, than one tree 16 inches in diameter, 35 feet high. From three smaller trees there will result a wider mass of foliage, and it will be easier for those not equipped with large tree-moving apparatus to handle the three smaller trees.

If the earth is dissected out from the roots, two trees 8 inches in diameter could be carried by one team. They can be loaded on a low stone truck or handy wagon, the trunks of the trees resting on two benches which lessens the breakage of roots and top. Trees can be loaded by the men, the tree being tipped over on the truck which stands beside the hole.

9 feet in diameter with trees 10 to 18 inches, on a low truck consisting of a platform hung under four heavy wheels, the tree being lashed fast to a collar and pole on the rear axle, and pulled over to the rear and then the platform chained fast to the rear axle. The roots outside the ball are usually cut off. With elm trees carrying a slender top this method succeeds, although the trees are often slow in recovering. It succeeds with maples, but they are likely to grow slowly or die back until the tree reestablishes a balance, after several years.

Deciduous trees can be moved in midsummer in full

331. Diagram to illustrate the operation in the removal of a large tree for transplanting.

The tree is shifted into position by the men lifting on the trunk, or it may be lifted by a shear pole derrick or single pole. Many people hesitate about moving large trees and wait fifteen years for a result they could easily secure in this manner, by collecting wild trees in the vicinity.

Root-pruning a year in advance may aid in moving a tree, but is not essential. If a trench is to be dug at a radius of 4 feet all the way around a tree 10 inches in diameter, it is better to move the tree with a wider spread of roots and take good care of it. A root-pruned tree is likely to be neglected and suffer for moisture. The tree can be root-pruned three-quarters of the way around for one season and perhaps be in better condition for moving. This is more likely to be beneficial with a tree with long coarse roots and with few fibers in the center, like a black oak. A mistake is frequently made in assuming that a ball of earth is all that is essential, regardless of the amount of fibrous roots in the ball and of its area to gather rainfall as compared with the top. Frequently trees dug around the roots cut off at a diameter of 10 feet, have the tree-mover sent for when they should have a spread of roots of 30 feet. The ball-of-earth method with deciduous trees usually consists in carrying a ball of earth 7 to

leaf. Norway maples 7 inches in diameter were well watered to fill them with sap; the next day they were dug with roots spreading 15 feet, leaving a ball of earth 5 feet in diameter in the center. The tree was tipped back and a platform or stone boat moved under, on which it was moved. After planting the trees were watered about four times, once in ten days. The ball of earth became dry very quickly. The bundles of outer roots did not send out fibers for about two weeks. Trees with less fibers in the center would probably not succeed so well. See also *Drainage* and *Evergreens* for further discussion.

HENRY HICKS.

#### Types of insect injury to trees.

Trees of all sorts are liable to injury by many kinds of insects, so many indeed that it is difficult to present a satisfactory account of their depredations without going into great detail. A few insects stand out preëminently, however, among the more common and widespread tree pests and a selected series of these will serve as examples of the various ways in which the trees may be injured by these animals.

Destructive forest- or shade-tree insects may be grouped into two classes, according to the way in which

332. Diagram to show how and where the digging is begun.

they feed, based on the fact that one series feed by chewing and consuming the tissue of the trees, while the members of the other class derive their nourishment from the juices or sap of the trees which they suck out by means of needle-like sucking mouthparts. Most insects pass through three, or at least two, preparatory stages, very different from the adult, before they reach maturity. They hatch from eggs deposited by the adult female, as larvæ (grubs, caterpillars, maggots, and so on) and in this larval stage feed till they attain their full size. The larval stage is, therefore, the most destructive one. When full grown, the larva usually changes to a resting condition or pupal stage (chrysalis), and during this time does not feed. Finally the adult appears and the life-cycle is complete. Many insects undergo a single

333. Lepidopterous caterpillar. ( $\times \frac{3}{4}$ )

generation every year, but a number grow more rapidly, producing several broods each season, while a few require two years or more to mature.

Insects provided with chewing mouthparts may feed on the leaves and are then known as defoliators; or they may feed on the bark, cambium, sapwood, heartwood, or roots, in which case they are known as borers. Caterpillars, beetle grubs and saw-fly larvæ are the most important insects of the latter kind.

Among the insects with piercing mouthparts, some suck the juices of leaves, while others affect the twigs and branches, or even the roots. Plant-lice and scale insects are the most important insects of this kind.

#### *Methods of destroying tree-pests.*

There are five widely different methods of destroying insects which injure trees, and the selection of an appropriate method must depend primarily on the feeding-habits of the species to be dealt with.

(a) *All defoliators*, such as caterpillars (Fig. 333), saw-fly larvæ (Fig. 334), and those beetle larvæ that feed externally upon the leaves, are best killed by the application of an arsenical poison (Figs. 335, 336). This is applied preferably by some sort of a spray-pump that throws a fine mist or spray of water in which the arsenical has been mixed. Such spraying machines may be obtained in sizes to suit any needs, from hand-pumps holding a quart of liquid to power sprayers equipped for spraying extensive woodlands thoroughly and rapidly. The most satisfactory poison is arsenate of lead, an insoluble arsenical which can be mixed with water in the proportion of six to ten pounds to each 100

334. Sawfly caterpillar. (Natural size.)

gallons of water and sprayed upon foliage without danger of damage to the leaves. It is sold commercially as a white paste and is easily handled. This substance is far superior

to paris green, london purple, and the like. It should be applied only in sufficient amount to show after drying as whitish specks upon the surface of the leaves. (b) *Plant-lice*, since they feed by inserting their beaks into the tissues of the leaves, and other soft parts, are not affected by arsenicals and must be destroyed by spraying with what is known as a contact insecticide, one that kills through the application upon the surface of the insect's body. The most generally used, and one of the best contact insecticides is kerosene emulsion. This is prepared by dissolving half a pound of common laundry soap in one gallon of hot water and then adding two gallons of kerosene while stirring or churning the mixture violently. The creamy mass thus formed thickens on cooling and must be diluted with nine times its volume of water before being sprayed upon the

plants. Scale insects feed like plant-lice, by inserting their delicate beaks into the tissue of the tree and sucking out the sap, but usually occur on the thin bark of the branches and twigs rather than on the leaves. Each insect secretes a scale-like covering beneath which it lives while growing, and, even when adult, the female never leaves her position beneath the scale. As the scaly covering is of a waxy nature, these insects are not so easily destroyed by contact insecticides as are plant-lice, although kerosene emulsion is sometimes effective, especially in the case of young insects which have not yet secreted a thick scale. Many older or more resistant scales cannot be destroyed in this way and they may be killed when the trees are in a dormant condition by a spraying with lime-sulfur wash prepared as follows: Water, forty gallons; fresh lime, twenty pounds; flowers of sulfur, fourteen pounds. These are boiled together for one hour and then applied as a spray to the branches and twigs. This wash should never be sprayed upon trees when in leaf.

335. Injury by leaf-eating caterpillar of small size.

(c) *Bark-beetles*.—These are small insects that live during the larval stages beneath the bark of the trunk and branches of trees. The parent insects enter the bark and excavate a small tubular gallery through the cambium or inner bark. Along the sides of this, the eggs are laid and the developing larvæ eat out sinuous burrows through the cambium. They thus interfere with the sap-flow and cause a general weakening or even death of the tree. Bark-beetles are liable to attack sickly or dying trees, and the only feasible method of lessening their depredations is to remove and burn such trees or branches as are affected, in addition to improving in all possible ways the conditions under which the tree is growing, bearing in mind that healthy trees are much less likely to be troubled by these insects than are weak, poorly nourished ones.

(d) *Wood-borers*.—The larvæ of certain beetles and moths subsist upon the woody tissues of trees, excavating galleries through the wood of both living and dead trees. Such larvæ are usually whitish, often with brown head and have powerful jaws, by means of which they can cut through the solid wood. They may attack trunk, branches, or twigs, some working in the sapwood, others in pith, while a few feed mainly on the heartwood. Insects of this kind are the most difficult to combat as they feed where they cannot be reached by means of insecticides during the greater part of their life. Due to their concealed position, they are not so readily noticed and may frequently cause irreparable damage to trees before their presence is recognized. Besides cutting out the individual larvæ or destroying them in their burrows by means of a piece of wire, no general method of destruction can be recommended. It is important, however, to maintain the trees in as healthy condition as possible, and to remove all dead or dying timber in order to reduce the number of breeding-places for the insects.

(e) *Leaf-miners*.—To this class belong some of the

336. Injury by leaf-eating caterpillar of large size.

members of several different groups of insects, certain small moths, a few saw-flies and a small number of flies and beetles. All of the leaf-miners are very small insects whose larvæ feed upon the parenchyma of the leaf, leaving intact the upper and lower epidermis. In this position they are protected from most sorts of

337. Tussock moth larva. ( $\times \frac{1}{2}$ )

insecticides, although in some cases, spraying with a contact insecticide containing some tobacco compound in combination with soap may be efficacious. One formula recommended is: water, 800 gallons; nicotine, or "blackleaf 40," one gallon; laundry soap, thirty-two pounds. Ordinarily, leaf-miners do not present a serious menace to trees, but the presence of their blotch-like or serpentine galleries, which show as faded areas, often greatly disfigure the leaves.

*Some of the more important shade-tree pests.*

#### A. Defoliators.

The tussock moth, *Hemerocampa leucostigma* (Fig. 337), is perhaps the most abundant caterpillar on trees, particularly in thickly settled districts. The eggs are laid in the fall in white fluffy masses the size of a dime on the trunks of infested trees and hatch in the early summer. The larvæ bear several pencils of long black hairs placed at each end and have four brush-like tufts of pale yellow hairs above, with a bright red head. These pupate early in July in crevices in the bark and the adults soon emerge to lay the eggs for a second generation of caterpillars which will mature before fall into moths that deposit the over-wintering eggs. The female moth is without wings and lays her mass of eggs on the bark where she emerges from her pupa case. These caterpillars feed on all sorts of trees except evergreens, but seem to be most destructive to maple, elm and American linden. Two related caterpillars have been imported from Europe into Massachusetts, the gypsy moth and brown-tail moth, and although these are at present confined to that neighborhood, they will undoubtedly become widespread before many years have elapsed. The gypsy caterpillars feed on many kinds of trees, preferring oaks; they may be recognized by a double line of round spots down the middle of the back, blue, followed by red ones. Their life-cycle is like that of the tussock moth, except that there is only one generation passing the winter as a mass of woolly, dull ochre-yellow eggs attached to the bark. The brown-tail is a brownish caterpillar with white spots, passing the winter in small woven silk nests containing many caterpillars. The nests are attached to the tips of the twigs of infested trees. Orchard trees suffer most severely from this species, although all sorts of broad-leaved trees are attacked.

338. Cocoon of bag-worm. ( $\times \frac{1}{2}$ )

Another common caterpillar of very different habits is the American tent-caterpillar, *Malacosoma americana*. This is an inconspicuous brownish moth which over-winters as a band-like mass of eggs placed around twigs of cherry and a number of other trees. These hatch in very early spring and the larvæ spin silken nests in small forks of the branches from which they crawl out to feed upon the opening leaves. They mature

in early summer and the eggs are laid in midsummer for the next season's brood.

The bag-worm, *Thyridopterix ephemeraformis*, is a defoliator at times very destructive, although each larva in his dependent bag does not have a wide range of operations. Fig. 338. Hand-picking and arsenical sprays are the remedies.

The caterpillars of the mourning cloak, *Ewanessa antiopa* (Fig. 339), are a very common pest of elm and other shade trees. They are black, coarsely spiny caterpillars with red spots along the back, and feed more or less in colonies, usually defoliating single branches at a time. The butterfly passes the winter as an adult, appearing in very early spring, and laying its eggs in May. The caterpillars from these eggs become full-grown before July, and the butterflies of another generation appear in July to lay eggs which will give rise to the hibernating butterflies of the next winter.

339. *Ewanessa antiopa*. ( $\times \frac{1}{2}$ )

A common saw-fly which occurs on willows is the American saw-fly, *Cimbex americana*. The larvæ are much like the defoliating caterpillars of moths and butterflies in appearance and feed in the same way, destroying the entire leaf-tissue. The larvæ are pale green, with a blackish line down the back. When mature, they descend to the base of the tree, where they spin parchment-like brown cocoons in which to pass the winter on the ground among fallen leaves. In the spring, they transform and the adult saw-flies deposit their eggs singly in slit-like cuts made into the tissue of the leaf.

Pine trees often suffer from the depredations of saw-fly larvæ of the genus *Lophyrus* which devour the needles, near the bases of which they later spin their small cocoons.

Many saw-fly larvæ feed only on the leaf from one side, leaving the epidermis of the other side intact. Arsenical sprays for the destruction of such species must be directed against the side of the leaves attacked, usually the under surface.

Among defoliating beetle larvæ, the imported elm-leaf beetle, *Galerucella luteola* (Fig. 340), is probably most important. This occurs only in the eastern states but is gradually spreading into the middle West. The small, yellow, two-striped adults live through the winter and deposit their bright yellow eggs in small masses on the under side of elm leaves in early spring. These eggs hatch into black and reddish slugs which feed on the under surface of the leaves, leaving only the veins and upper epidermis. The leaves then dry up and may fall off. The larvæ, now changed to a yellow color, descend to the surface of the ground to pupate and soon emerge as a summer generation of beetles. There are two or three annual broods, according to the latitude.

340. Larvæ of elm-leaf beetle. Holes made by adults, surface marks by larvæ.

#### B. Plant-lice and scale insects.

There are many kinds of plant-lice (Fig. 341), but all pass through very similar life-cycles. In general, this is as follows: the winter is passed as a large, shining, elongate-oval egg attached to a twig or branch. This gives rise in the spring to a soft-bodied wingless female aphid that gives birth to living young aphids, which in turn reproduce in the same way. These suck the juices from leaves, petioles or tender twigs and thus sap the vital-

ity of the tree. In addition, the leaves may be disfigured by a sticky substance, known as honey-dew, secreted by the insects. In the fall, both females and winged males are produced and the female lays a single winter egg. On account of their method of reproduction, plant-lice multiply very rapidly, especially in damp seasons. Some species have a more complicated life-cycle, producing winged individuals in the summer which migrate to another food-plant, later to return in the fall to the original one.

A few plant-lice living in colonies produce galls, curled leaves, or other malformations on the leaves or twigs of infested trees.

Scale insects exhibit a greater variety in their seasonal history; some pass through a single generation each year, while others multiply more rapidly, passing through a number of generations annually. The winter is sometimes passed in the egg state, but more commonly as a partly grown insect.

One of the commonest and most destructive scales is the oyster-shell scale, *Lepidosaphes ulmi*. This occurs on the thin bark of a great variety of trees, appearing as a very small, elongate, flattened body, pointed at one end and rounded at the other, with the upper surface more or less distinctly ridged in a transverse direction.

There is a single generation annually, the females maturing in late summer and depositing a mass of eggs which remains beneath the scale through the winter, hatching

341. Woolly aphid on alnus.

ing in the spring and producing full-grown insects by midsummer. Sometimes this species is so abundant that the smaller branches appear as if covered by a gray incrustation.

The San José scale, *Aspidiotus perniciosus*, is another important scale, which has been introduced into many parts of the United States. It is very destructive, primarily to certain orchard trees, but injures many thin-barked shade trees as well. The scale is very small, round in the female and oval in the male, with a minute nipple-shaped projection near its center. The females do not lay their eggs till the young insects are ready to hatch, so that they practically produce living young. These develop rapidly, five or six broods maturing each season, of which the last hibernates in the half-grown condition. In mass, the scales form a gray, granular crust, covering the branches and twigs.

In some parts of the country, maples grown for shade trees suffer great injury by the cottony maple scale, *Pulvinaria innumerabilis*. This scale is most conspicuous on the twigs in early summer, at which time the females are depositing their eggs. It then bears a tuft of fluffy waxen substance resembling a bit of white cotton. The young scales appear soon after, when they migrate to the leaves and feed till early fall before returning to the twigs, where they finally pass the winter in a half-grown condition.

Practically all sorts of trees suffer at times from scale insects, of which there are many kinds. The common forms are divisible into two groups, the soft scales and armored scales. The former are soft and convex like the cottony maple scale, in which the "scale" is the back of the insect itself; the latter are usually smaller, like the San José scale, in which the "scale" is a separate waxen cover secreted by the insect.

#### c. Bark-beetles.

These insects are small black or brown beetles that live in the larval stages beneath the bark, feeding on the inner bark and cambium, and all have very similar

habits. The parent beetle enters the bark through a small hole about the size of a pencil-lead, and excavates a single primary or egg-gallery through the cambium, usually grooving the sapwood. This tunnel varies from one to several inches in length, and along its sides the female cuts out little pockets, in each of which an egg is laid. On hatching from the eggs, the larvæ excavate individual mines usually more or less perpendicular to the egg-gallery. When full grown, the white legless grub-like larvæ pupate in cells excavated in the bark, from which the beetles emerge by chewing out a circular tunnel to the surface. Trees from which beetles have emerged appear as though the bark had received a charge of buck-shot, from the presence of the small circular emergence holes. Some forms, like the genus *Dendroctonus*, attack fine healthy coniferous trees and kill much valuable timber, but shade trees are more commonly attacked by the species that live in the bark of deciduous trees, more particularly those that are in a sickly condition.

342. Flat-headed borer.  
(Natural size.)

A common form is the hickory bark-beetle, *Eccoplogaster quadripinosa*, that attacks hickories. The beetles appear in June and July, to excavate the primary galleries which extend vertically for an inch or two. Forty or fifty eggs are placed in notches on the sides and the larvæ bore out at right angles, thus girdling the cambium and weakening or killing the branch. This species undergoes only one generation annually, although some others pass through two or more each season. There are many other kinds, all scarring the bark or surface of the wood in a similar way.

#### D. Wood-borers.

The larvæ of many beetles and moths, and of a few wasp-like insects, injure trees by excavating their food-burrows through the solid wood.

Birches, grown for shade or ornamental trees, often suffer great injury from the presence of a flat-headed borer, the bronze birch-borer, *Agilus anxius*. The small elongate bronze-green beetles appear in May or June and deposit their eggs on the branches, at first near the crown of the tree. The larvæ penetrate the bark, beneath which they cut irregular flattened galleries till grown, when they cut out cells in the wood in which to pass the winter before emerging in the spring. The upper parts of the tree suffer first and begin to die, and the following year the larvæ appear nearer to the ground. Chestnut is attacked by *Agilus bilineatus*, the two-lined chestnut-borer.

Most other kinds of trees suffer similar injury from related beetles, many of which multiply also in dead trees and stumps.

Another flat-headed borer, the larger flat-headed pine-borer, *Chalcophora virginienensis* (Figs. 342, 343), extends its flattened burrows deep into the wood of the tree, a method of feeding exhibited by many borers of this group attacking deciduous trees also. The larvæ grow to a length of 2 inches before cutting out their transformation cells in the bark.

Round-headed borers are similar in habits, but belong to another family of beetles in which the larvæ are less distinctly flattened near the head and excavate more nearly cylindrical burrows.

One of our commonest species is the locust-borer, *Cyrtene robiniae*, which attacks yellow locust trees. The elongate medium-sized black beetles, with brilliant yellow markings, appear in the early fall to deposit

343. *Chalcophora virginienensis*, adult of flat-headed borer.  
(Natural size.)

their eggs on the bark of the trees. The eggs soon hatch into larvæ which feed for a time and then over-winter in a small cell beneath the bark. Next year they bore through the living wood and transform in August to beetles. This species can destroy healthy locust trees rapidly and is a very serious pest wherever the tree is grown. All infested trees should be pruned or felled and burned to destroy the larvæ, in the fall or winter. Sugar maples suffer from a similar insect, as do practically all sorts of trees.

344. Injury to tip of white pine sapling by white-pine weevil. ( $\times \frac{1}{2}$ )

White pine trees are commonly deformed by the larvæ of the white-pine weevil which feed exclusively beneath the bark of the terminal shoots of young trees of this species. (Fig. 344.)

The carpenter moth, *Prionoxystus robinix*, is a large common mottled gray insect with pale yellow black-headed and black-speckled larvæ 2 inches in length, that bore in the branches of many kinds of trees. Oak suffers most, but maple, ash, locust, willow and cottonwood are often infested. The moth lays its eggs on the bark late in the summer, and for two or three seasons the larvæ feed on the wood, cutting large circular burrows. They transform in the burrow, the pupa working its way partly through the bark for the eclosion of the moth. The brown pupa-case may then remain projecting from the mouth of the burrow for some time. A related European insect, the leopard moth, *Zeuzera pyrina*, has recently become abundant along the northern Atlantic coast region, attacking elm and all sorts of other trees and shrubs. It feeds in the same way and bids fair to become one of our worst shade-tree pests. The larvæ of many other moths injure trees in a more or less similar way.

The pigeon horn-tail is a large cylindrical yellow-brown and black insect with grub-like larvæ that bore

345. Phylloxera galls on chestnut. ( $\times \frac{1}{2}$ )

in elm, maple, and other trees. The females insert their eggs deep into the tree by means of a needle-like ovipositor. They frequently fail to extricate the ovipositor and may be seen dead, but still attached to the tree trunks.

#### E. Leaf-miners.

Small larvæ belonging to several orders of insects live as miners in leaves, the most abundant forms often greatly disfiguring the foliage of affected trees.

Deciduous trees of all sorts are affected by the leaf-mining larvæ of various small moths, but it is very difficult to distinguish the different species without minute study. Oaks are particularly susceptible and are commonly disfigured by the sinuous or irregularly rounded mines that appear as pale streaks or blotches. Even pines suffer from such larvæ, which enter a needle and eat out the tissue, causing the tip to dry and become yellow. Occasionally insect larvæ cause malformations

or swellings of the leaves or twigs, known as galls. (Figs. 345, 346.)

Yellow locust suffers from a leaf-mining beetle larva, *Odontota dorsalis*, that eats out almost all of the leaf parenchyma, causing the leaves to dry and shrivel. Related species affect oak and basswood. Members of another family, belonging to the genus *Brachys*, also mine in leaves of oak, chestnut, and so forth.

One leaf-mining saw-fly is of considerable importance, *Kaliofenusa ulmi*, the larvæ of which eat out the parenchyma of elm leaves between the lateral veins, causing them to assume a seared appearance in spots (Fig. 347). Another closely related species mines in the leaves of the hawthorn (*Crataegus*). The latter may be satisfactorily killed by a spray of tobacco-water, but the species on elm is more resistant. The larvæ of these species enter the ground later in the summer to spin their cocoons.

#### Some types of tree diseases.

Disease in plants is the result of any derangement in the normal form, structure or physiology of the organism. The disease condition becomes manifest by different symptoms, according to the nature of the disorder. Such symptoms as stag-head, cankers, leaf-spots, witches' brooms, and so on, are examples of the effect produced in the tree by some disease-producing agent or combination of agents. The variety of functional disorders alone that may arise in trees is large. Such causes as insufficient or excessive soil water, malnutrition, excessive heat or cold, or rapid variations in temperature are capable of producing effects called physiological diseases. On the other hand are those diseases that are produced by the activities of parasites, such as certain of the fungi, and bacteria. Accurately to place a new or little-known disease in one of these two classes is often difficult for the expert, even after much study. There is relatively less known concerning the physiological diseases of trees than of those caused by parasites, not because of their less importance so much as of the difficulty of studying them. It is to be deplored that the diseases of forest, shade and ornamental trees have not received their due share of study and investigation by pathologists.

#### How fungi cause diseases of trees.

The fungi consist of a group of plants that do not contain chlorophyll, upon which all green plants depend for the synthesis of carbohydrates. Consequently, not being able to manufacture their own food, the fungi must secure it from their environment, by dissolving and utilizing organic materials from dead or living plant or animal bodies. By far the vast majority, luckily, belong to the class of scavengers which attack dead organic material and utilize it for food. These forms are called saprophytes. Other species of the fungi attack living plants and, through their activities, produce the disorders that are termed diseases. These are known as parasites or pathogens.

In brief, the general action of the fungi that cause tree diseases is as follows: The fungus exists in two stages, the vegetative and the fruiting. The vegetative stage consists of a mycelium, which is an aggregate of long much-branched microscopic threads of fungous cells. This mycelium penetrates and grows in the body of the tree, extracting nutriment from it by dissolving the different structures it can utilize. In this process the tissues of the tree are destroyed and the fungus obtains food for its further development. In time, after sufficient food has been stored in the mycelium, the fungus forms its fruiting bodies. In the case of the larger number of the heart- and sap-wood rots, this fruit body consists of a shelf-like or toadstool-like structure on the exterior of the tree. In these fruiting structures are borne millions of microscopic spores or seeds of the fungus, which are distributed largely by the wind. If by chance one of these spores finds lodgment on an exposed wound in the bark of a tree which it is capable of infecting, it will under proper conditions germinate, producing a mycelium that will penetrate the tissues of the new host.

#### Seedling diseases.

The young seedlings in the nursery beds are often attacked by certain soil organisms that cause a decay of the stem at the surface of the ground, allowing the plant to wilt and fall over. This type of disease is called "damping off," in many cases it is caused by the fungus *Pythium de Baryanum*. This disease is largely induced by very moist soils, a moist atmosphere, high temperature, and little ventilation. By growing seedlings in light sandy soils, well watered but not excessively, and by aerating the beds well to reduce the humidity of the atmosphere around the plants, this trouble is practically avoided. Soils in which it has once occurred should be abandoned, however. In greenhouses in which this disease is often troublesome and the precautionary measures mentioned above difficult to maintain it may be necessary to sterilize the soil with formaldehyde or by steam heat immediately before sowing the seed.

#### Leaf diseases.

Very little serious damage is caused by most leaf diseases of trees other than the unsightly appearance produced. There are a few leaf diseases, however, that are of more or less importance in the United States. Conspicuous among these is the anthracnose disease of oak and sycamore leaves, caused by the fungus *Gnomonia veneta*. Throughout northeastern United States in recent years the plane-tree (*Platanus occidentalis*) has been almost universally affected and the trees often completely defoliated before the first of July. Early in the season the disease becomes manifest by the production of rapidly enlarging brown blotches which are usually produced along the veins of the leaf. If examined closely, the numerous spore clusters can be seen. These clusters are composed of innumerable microscopic conidia which serve for the dissemination of the fungus.

The twigs are commonly affected also and on these, as well as the fallen leaves, the fungus winters over. The same fungus produces a similar disease on oaks, especially the white oak, and is often epidemic in certain regions. As a measure of prevention, all fallen leaves

and twigs from diseased trees should be carefully collected and burned. All diseased twigs should be pruned off and burned. If desirable, the trees may be sprayed with standard bordeaux mixture from the time the leaves begin to unfold, at periods of two or three weeks, until the first of July.

The tar-spot disease of the maple caused by *Rhytisma acerinum* is a conspicuous disease but seldom causes serious damage to the tree. Fig. 348. The diseased spots appear as blotches of tar on the upper surface of the leaves. Burning the diseased leaves will materially lessen the chances of attack the coming year since the pathogen winters in them.

Maple trees, at least in the north-eastern states, have suffered during the past few summers from a physiological trouble called leaf-scorch. The leaves of one side or the whole of the tree turn brown between the veins and finally dry up. This disease has been ascribed to over-transpiration of the leaf-tissues at a time of year when the roots cannot furnish enough water to the tree to compensate the loss. Thus the leaf-cells are killed by desiccation and the brown blotches appear. It is advised that artificial watering during hot, dry weather will materially lessen the severity of the trouble, especially under city conditions.

#### Canker diseases.

A diseased condition of the limbs or trunk of a tree that results in the death of an area of the bark is termed a canker. These cankered areas may be either sunken or enlarged, and the terms necrotic and hypertrophy cankers are used respectively to designate these characters. Not all cankers are produced by parasitic organisms; some are the result of malnutrition, winter injury, sun-scorch, insects, and the like.

By far the worst epidemic disease of trees in America is the chestnut-canker now prevalent in many of the eastern states. In all, a total loss of \$25,000,000 has been ascribed to this disease between the time it was first noticed, in 1904, on Long Island, and the year 1912. The cankers produced on the chestnut are caused by the fungus *Endothia parasitica*. Fig. 349. At present, the question of the origin of this disease in the United States is undetermined. The fungus works rapidly in the bark and sap-wood, killing the tissues. Fruiting bodies of two types are formed on the diseased bark, a conidial stage that appears as long yellow tendrils of gelatinous matter and the reddish yellow to dark brown cushion-like stromata that contain the ascospores. These latter spores are ejected in large numbers at every rainy period throughout the spring, summer, and fall and are carried by the wind, readily causing new infections. On the individual tree, the fungus is rapidly spread by the washing down of the conidia into wounds in the bark. The cankered areas soon cause the death of the parts above by girdling the limb and, in most cases, complete death of the tree follows in two or three years. The state of Pennsylvania has taken steps to eradicate this disease by seeking out diseased trees and compelling owners to cut all affected trees in the western half of the state. The extremely virulent nature of the disease, however, has led more conservative pathologists to question the advisability of expending large sums of money with so slight a chance of ultimate or complete success. The

349. Canker disease of the chestnut produced by the fungus, *Endothia parasitica*. The conidial tendrils are produced from the numerous ruptures shown in the bark.

348. Maple leaf affected by the tar-spot fungus, *Rhytisma acerinum*.

problem of saving individual trees in affected regions has not been solved. The very nature of the disease precludes spraying, and tree surgery methods have not given anything more than temporary success. Incipient cankers are so difficult to locate and, by producing conidia

350. Stem of white pine tree attacked by the white pine blister-rust fungus, *Cronartium ribicola*. The fruiting stage is here shown in the process of rupturing the bark.

when only three or four weeks old, serve to spread the fungus so rapidly over the tree that human efforts so far have failed.

**Rust diseases.**

The most destructive and important rust diseases of trees are those caused by different species of the *Peridermium* on coniferous trees. These rust fungi attack the needles, twigs, or limbs of coniferous trees, often producing defoliation or complete death of the tree. Notable among these diseases is the white-pine blister-rust caused by the *Peridermium* stage of the fungus *Cronartium ribicola* (Fig. 350) which has its *Cronartium* stage on species of currants and gooseberries. The fungus is not native to this country but has recently been imported from Europe. In Europe the disease has practically exterminated the white pine (*Pinus Strobus*) in many localities, and in this country the danger of a similar destruction of this species is now being faced, if the fungus acts with the same virulence as in its native environment. In 1912 the Federal Board of Horticulture placed a quarantine on most of the countries of Europe, which prevents anyone bringing white pine trees from these countries into the United States. The fungus attacks white pine from one to twenty years old, the mycelium growing in the bark and usually producing a swelling.

351. Black spruce attacked by the dwarf mistletoe, *Arceuthobium pusillum*, causing witches' brooms.

The orange-yellow fruiting bodies burst through the bark in one to five years after infection. The spores from the pine can affect the gooseberry or currant leaves only. On these hosts other kinds of spores are borne in the fall which can infect the white pine only and thus the yearly cycle is completed. The black currant (*Ribes nigrum*) is by far the most virulently affected in this country, and it is advised that plants of this species are therefore extremely dangerous to the white pine industry and their culture should be discouraged. By keeping currants and gooseberries at least 500 feet away from white pines, a partial safeguard is provided against the passing of the fungus from one host to the other. All plants affected by this fungus should be imme-

diately destroyed. Consult Bureau of Plant Industry, U. S. Dept. of Agric., Bulletin 206 for further details.

#### Witches' broom diseases.

Excessive branching at any point on a limb, forming a compact cluster of short stubby branches, is often caused by numerous agents, both insect and fungus, as well as by the mistletoes. In the South, especially, trees of many species are disfigured by these witches' brooms caused by the American mistletoe, *Phoradendron flavescens* and related forms. In the northern states the dwarf mistletoe, *Arceuthobium pusillum* (Fig. 351) causes similar brooms on the black spruce (*Picea Mariana*). Witches' brooms on red cedar (*Juniperus virginiana*) are caused by the rust *Gymnosporangium nidus-avis*.

#### Root diseases.

The principal root disease of trees that is widely distributed throughout the United States is that caused by the mushroom *Armillaria mellea*. Fig. 352. The mycelium of this fungus grows in the soil on decaying wood as a saprophyte, but can also become parasitic, killing trees over large areas. Almost any of our indigenous trees may be affected with this disease. Fruit trees often suffer in certain regions. The mycelium penetrates the roots and grows in the bark and wood, working up into the base of the tree.

The destruction of the root-system is so rapid, however, that two or three years after infection the tree often dies, before the fungus has spread any great distance up the trunk. In the older decayed parts of the root and in the soil, the mycelium is aggregated into long black, flattened strands called "rhizomorphs," or more commonly termed, "shoe-strings."

352. Base of young white pine tree attacked by *Armillaria mellea*. Note the cake of earth around the tree due to the exudate of resin, also the white mycelium felts within the bark and the enlarged resin vesicles induced by the fungus. The slender strands clinging to the cake of earth are the "shoe strings."

which forms the surrounding soil into a cake. The disease may be recognized by the gradual yellowing of the foliage, decay of the roots, presence of the "shoe-strings" in the soil, and the appearance of the honey-yellow mushrooms around the base of the tree. No practical method of treatment is known. Diseased trees and the mushrooms should be destroyed.

Other soil organisms may enter through wounds in roots and cause diseases. Such a disease may, after becoming established in the roots, continue to spread up the trunk. Thus wounded root-systems are as dangerous a source of infection as wounded branches. Roots often suffer from winter injury largely because the wood ripens from the top of the tree downward, and when severe conditions are undergone early in the winter before the new wood of the roots has ripened, it is killed.

*Heart-rot diseases.*

Most of the wood-rotting fungi belong to a class known as the wound parasites. By far the most universally distributed and destructive of these is the shelf fungus, *Fomes igniarius* (Figs. 353, 354), which causes the white heart-rot of deciduous trees. Infection may occur in any part of the tree where wood is exposed. The mycelium, by dissolving the lignin of the woody elements, first causes a brown decay that is later succeeded by a whitish decomposition, at which stage very little of the original woody structures is left. This decomposition of the heartwood takes place rapidly and often the tree is blown over. The fruiting bodies of this fungus are produced usually at the point of infection. They consist of large hoof-shaped bodies, carbonaceous and rough on the upper surface, and brown beneath. The under surface is full of small holes which are the openings of long vertical tubes, on the inner surface of which the spores are borne. These spores sift out of the tubes and are distributed by the wind.

Another fungus commonly met with, and acting similarly, is *Fomes fomentarius*. This is also at times a wound parasite but works mostly in the sapwood first and later spreads into the heartwood. A yellowish white, soft decay is produced. Large sheets of a chamois-skin-like character are often found in trees rotted by this fungus. These sheets are compact masses of the mycelium which have filled up the long cracks produced by the shrinking of the diseased wood. The sporophores are essentially different from those of *F. igniarius*, being light gray and smooth on top and light gray-brown beneath, with relatively large pores. Numerous other shelf fungi occur as wound parasites and do more or less damage where the bark, when wounded, was not protected until the natural callus could form. Some of the fungi which are wound parasites of living trees continue a saprophytic life in structural timbers, causing their ultimate destruction.

*Winter injury, sun-scald and drought*

Many misconceptions are prevalent concerning the real effect of freezing and sun-scald on trees. The injury by freezing in trees is due to the action of low temperature upon the water in the cells of the tree or to the tension pressures induced. As the temperature approaches freezing, the water in the cell begins to pass out into the intercellular spaces and there accumulates. The lower the temperature goes, the more water is extracted from the cell and stored in the intercellular spaces as ice crystals. When a certain temperature is reached, the amount of water withdrawn is such that the living elements of the cell can no longer survive, and are killed. This specific minimum temperature varies for different species of trees, accounting for the difference in susceptibility to winter injury. The living tissues of the tree constitute the bark and sapwood, and when areas of these tissues are killed, serious damage is done to the tree. Either enough damage is done to the roots, trunks, or twigs to cause ultimate death the coming summer, or the areas that were killed serve as infection courts for the various wound parasites like the heart-rot or sap-rot fungi. In the case of sun-scald, the action is exactly similar, with the exception that the water is removed from one side of the tree by excessive heat during the growing season, instead of by freezing. The cracking and splitting of the bark of trees may be due to the tension pressure set up in the bark by the contracting of the woody cylinder in circumference during periods of low temperature.

Norway maple trees planted for shade are especially susceptible to sun-scald because they are grown close together in the nursery to a large size and then, when planted out, they are often injured by the hot sun. Care should be taken not to attempt to grow trees farther north than their natural range, which is an

indication of their ability to withstand the minimum temperatures.

Trees suffer in dry seasons from drought. Water is transpired from the leaves of a large tree, in great quantities. The hotter and dryer the atmosphere, the more water is transpired. Thus it happens that during continued droughts there is not sufficient soil-water present for the roots to supply the requisite quantity to compensate for this large loss, and the leaves are killed by dessication. Dead tops or stag-head ultimately result in cases in which such conditions continue year after year. Artificial watering in such cases will relieve this condition and largely prevent the trouble.

Excessively wet soil will also act in a similar way. Tree roots in saturated soil are unable to take up water because they are suffocated by the lack of oxygen. Hence the tops suffer as from drought.

*Smoke and gas injury.*

In manufacturing districts in which large quantities of smoke are produced, extensive injuries to trees as well as other vegetation often result. The injurious property of the smoke is mainly due to the sulfur

353. Sporophore of *Fomes igniarius* var. *nigricans*. Spore-bearing surface shown by the lighter color.

dioxide that it contains. This gas, when dissolved in the cell-sap of the leaf or the soil-water, produces sulfuric acid, which is poisonous to the tree.

The roots of trees are also injured by escaping sewer-gas or illuminating gas, which either poisons or suffocates the roots. Trees killed by escaping gas in the soil usually shed their outer bark in large patches near the base, the inner bark remaining tightly appressed to the tree.

Trees that come into contact with electric wires are injured in proportion to the strength of the current and the duration of the contact. Often trees are killed in cities from this cause.

Gases arising from recently laid creosoted paving-blocks or macadam bound with tar often cause defoliation of nearby trees, by the poisoning of the cell-contents of the leaves.

*Sanitary measures for the prevention of diseases.*

(1) As a first means of preventing disease in trees, one should buy clean stock from nurseries regularly inspected by state agents. Stock should be bought from nurseries in this country, owing to the great danger of importing diseases which might become epidemic. (2) In addition, one should use his influence in getting his neighbors to eradicate diseased trees and diseased parts of trees. Clean stock grown in a well-cared-for neighborhood is the problem half solved. (3) The litter of leaves or twigs under a diseased tree should be collected

each fall and carefully burned in order to prevent the wintering over of harmful fungi. (4) Care should be taken that all wounds made in pruning or by accident be immediately treated with some waterproof adhesive to prevent infection by wound parasites. In the absence of anything like accurate knowledge concerning better preparations, coal or gas tar and lead paint are to be recommended. The tar will last longer than the paint. The whole idea of wound-protection is to bridge over the time lapsing between the injury and the natural healing of the wound by the callus. Wounds previously treated should be gone over at least once a year and a new coating applied if necessary.

#### *Prevention of leaf diseases.*

Although the most of the damage done by leaf diseases is mainly to the appearance and not to the life of the tree, it may even be desirable to prevent the unsightly appearance of leaf-spot or other diseases of that

nature. If, after the sanitary methods described above fail to control the disease, it is desired to spray, this can be done at some little expense if the trees are not too large. Bordeaux mixture, full strength or half strength, applied three or four times after the leaves begin to show, at intervals of about three weeks, will probably tend to lessen infection in most cases. Spray mixtures should be applied a few hours previous to general rain periods, the advance of which can be predicted

354. Cross-section of maple limb affected by *Fomes igniarius*. Note that the frost crack was possibly the infection court. A young sporophore is shown just emerging at the top of the picture. ( $\times \frac{2}{3}$ )

by observing the government weather maps. General directions about spray mixtures and spraying machinery is now attainable from almost any one of the State Agricultural Experiment Stations.

#### *Treatment of diseased trees.*

When the woody part of the tree is the diseased area, tree-surgery methods must be used. Badly diseased limbs and twigs should be pruned off flush. Never leave a stub. Wounds so made should immediately be coated with a waterproofing. Decayed parts of larger limbs or trunks should be carefully dug out with a gouge and mallet, being sure to remove far back on all sides of the cavity into apparently healthy wood. The growing mycelium of the fungus is advancing some distance beyond the decayed area, in what appears as healthy tissue, and must be removed to effect a stoppage of the decay. Cavities thus made may be filled with concrete or left open, provided, in either case however, that the entire surface exposed is carefully painted with a waterproofing paint or tar. Diseased roots may be treated in the same way. At the present time no method of treating diseased trees internally is known. The ideas of quacks who may advance such treatments should be doubted, for in the majority of cases such treatments will prove to be harmful. The matter of chemo-therapy for the cure of tree diseases is not without hopeful outlook, but much careful investigation by experts must be forthcoming before such methods can be evolved.

W. H. RANKIN.

#### *Choice of trees for special purposes.*

The following lists include trees of proved hardiness and are not intended to be complete but merely suggestive, and chiefly for the northeastern United States and Canada.

### 1. TREES WITH SHOWY FLOWERS.

#### *A. Blooming in early spring before or with the leaves.*

*Acer rubrum* (fls. blood-red).  
*Amelanchier canadensis* (fls. white).  
*Cercis canadensis* (fls. rosy pink).  
*Cornus florida* (fls. white, also pink).  
*Cornus mas* (fls. yellow).  
*Magnolia denudata* (fls. white).  
*Magnolia Soulangiana* (fls. white to purple).  
*Prunus americana* and other plums (fls. white).  
*Prunus Avium* and other cherries (fls. white).  
*Prunus Davidiana* (fls. pink, also white, the earliest of all *Prunus*).  
*Prunus pendula* (fls. pinkish, branches pendulous).  
*Prunus Sargentii* (fls. light pink).  
*Prunus serrulata* (fls. white to pink).  
*Pyrus baccata* and other species (fls. white to pink).  
*Salix* (staminate plants with yellow catkins).

#### *AA. Blooming late in spring after the leaves.*

*Æsculus Hippocastanum*, and other species (fls. white or red).  
*Catalpa speciosa* (fls. white).  
*Cladrastis lutea* (fls. white).  
*Cornus kousa* (fls. white).  
*Crataegus* (fls. white).  
*Fraxinus Ornus* (fls. white).  
*Laburnum* (fls. yellow).  
*Magnolia hypoleuca* (fls. white).  
*Pterostyrax* (fls. white).  
*Robinia* (fls. white or light pink).  
*Syringa vulgaris* (fls. white to purple).  
*Tamarix parviflora* (pink).

#### *AAA. Blooming in summer and autumn.*

*Aralia chinensis* and *A. spinosa* (fls. Aug. and Sept.).  
*Castanea dentata* (fls. white; July).  
*Gordonia pubescens* (fls. white; Sept., Oct.).  
*Kœlreuteria paniculata* (fls. yellow; July, Aug.).  
*Oxydendrum arboreum* (fls. white; July, Aug.).  
*Rhus semialata* (fls. white; Aug., Sept.).  
*Robinia neomexicana* (fls. light pink; Aug.).  
*Sophora japonica* (fls. white; Aug.).  
*Syringa japonica* (fls. white; July).  
*Tamarix gallica* (fls. pink; Aug., Sept., if severely cut back).

### 2. TREES WITH SHOWY FRUITS.

*Acer pseudoplatanus* var. *erythrocarpa* (fr. bright red).  
*Acer rubrum* (fr. bright red in May and June).  
*Ailanthus altissima* var. *erythrocarpa* (fr. red).  
*Cornus florida* (fr. scarlet).  
*Cotinus coggygria* (ample feathery panicles).  
*Crataegus mollis* and others (fr. scarlet or red).  
*Hippophaë rhamnoides* (fr. yellow).  
*Ilex opaca* (fr. red).  
*Magnolia hypoleuca* (fr. scarlet).  
*Magnolia tripetala* (fr. pink).  
*Pyrus baccata* and allied species (fr. yellow or scarlet).  
*Rhus typhina* (fr. scarlet).  
*Sassafras* (fr. dark blue with red stems).  
*Sorbus americana* and *aucuparia* (fr. red).  
*Taxus baccata* (fr. scarlet).

### 3. TREES VALUED FOR FOLIAGE EFFECTS. (See also Section 5, Evergreens, next page.)

#### *A. With colored foliage.*

*Acer Negundo* var. *argenteo-variegatum* (the most effective of hardy variegated trees).  
*Acer Negundo* var. *aureo-marginatum* (lvs. yellow).  
*Acer palmatum* var. *atropurpureum* (lvs. purple).  
*Acer platanoides* var. *Reitenbachii* (lvs. becoming dark red in summer).  
*Acer platanoides* var. *Schwedleri* (lvs. bright red in spring).  
*Acer pseudoplatanus* var. *Worleei* (lvs. yellowish).  
*Betula alba* var. *purpurea* (lvs. purple).  
*Fagus sylvatica* var. *purpurea* (lvs. purple).  
*Populus alba* var. *nivea* (lvs. white beneath).  
*Populus deltoides* var. *aurea* (one of the best yellow-leaved trees).  
*Quercus pedunculata* var. *atropurpurea* (lvs. purplish).  
*Quercus pedunculata* var. *Concordia* (lvs. yellowish).  
*Salix alba* var. *argentea* (lvs. silvery white).  
*Tilia tomentosa* (lvs. white beneath).  
*Ulmus campestris* var. *argenteo-variegata* (lvs. whitish).

#### *AA. With large, bold foliage.*

*Acanthopanax ricinifolium*.  
*Acer insigne*.  
*Acer macrophyllum*.  
*Aralia chinensis* and *A. spinosa*.  
*Asimina triloba*.  
*Catalpa speciosa*.  
*Magnolia macrophylla*.  
*Magnolia tripetala*.  
*Paulownia tomentosa*.  
*Quercus dentata*.

X. Arboriculture.—*Picea pungens*, the Colorado blue spruce.

## TREES VALUED FOR FOLIAGE EFFECTS, continued.

AAA. *With small, narrow, or finely cut foliage.*

Acer palmatum var. dissectum.  
 Acer platanoides var. Lorbergii.  
 Acer saccharinum var. Wierf.  
 Alnus glutinosa var. imperialis.  
 Betula pendula var. dalecarlica.  
 Elæagnus angustifolia.  
 Fagus sylvatica var. asplenifolia.  
 Gleditsia triacanthos.  
 Gymnocladus canadensis.  
 Hippophaë rhamnoides.  
 Juglans regia var. laciniata.  
 Quercus pedunculata var. filicifolia.  
 Salix nigra.  
 Sambucus nigra var. laciniata.  
 Tamarix gallica, etc.  
 Taxodium distichum.

## 4. TREES WITH BRILLIANT AUTUMNAL TINTS.

Acer rubrum (scarlet).  
 Acer saccharum (scarlet and orange).  
 Cornus florida (scarlet).  
 Cercidiphyllum (yellow and purple).  
 Crataegus (mostly scarlet and orange).  
 Fraxinus americana (yellow or violet-purple).  
 Liquidambar (scarlet).  
 Liriodendron (bright yellow).  
 Nyssa sylvatica (scarlet).  
 Oxydendrum arboreum.  
 Quercus alba (vinous purple).  
 Quercus coccinea, palustris (scarlet).  
 Rhus (mostly scarlet).  
 Sassafras (orange and scarlet).

## 5. EVERGREEN TREES.

A. *Conifers.*

Abies.	Pinus.
Chamaecyparis	Pseudotsuga.
Juniperus virginiana.	Thuja.
Picea.	Tsuga.

AA. *Broad-leaved evergreens (only Ilex opaca and Rhododendron hardy in the N.).*

Ilex opaca.	Persea carolinensis.
Magnolia glauca (not fully evergreen as far north as it is hardy).	Prunus caroliniana.
	Prunus lusitana.
	Quercus virginiana.
Magnolia grandiflora.	Rhododendron maximum.

## 6. DECIDUOUS TREES VALUED FOR THEIR WINTER EFFECTS.

Acer Negundo (branches light green).  
 Acer pennsylvanicum (striped bark).  
 Betula nigra (flaky reddish brown bark).  
 Betula papyracea (smooth, silvery white bark).  
 Crataegus viridis, C. nitida and other species (red fruit).  
 Fagus sylvatica (keeps its dead leaves).  
 Gleditsia (large, flat pods).  
 Hippophaë rhamnoides (yellow berries).  
 Liquidambar (corky branches).  
 Pyrus prunifolia (scarlet or yellow fruit).  
 Quercus alba, pedunculata and tinctoria (keep their leaves).  
 Quercus macrocarpa (corky branches).  
 Rhus typhina (scarlet fruit).  
 Salix vitellina (yellow branches).  
 Sorbus americana and S. aucuparia (scarlet fruit).

## 7. VERY TALL TREES.

Gleditsia triacanthos.	Populus deltoides.
Juglans nigra.	Quercus macrocarpa.
Liriodendron Tulipifera.	Quercus palustris.
Picea excelsa.	Quercus rubra.
Pinus strobus.	Quercus velutina.
Platanus occidentalis.	Taxodium distichum.
Populus balsamifera.	Ulmus americana.

## 8. COLUMNAR OR NARROW PYRAMIDAL TREES.

Abies (most species).  
 Acer saccharinum var. pyramidale.  
 Acer saccharum var. monumentale.  
 Betula pendula var. fastigiata.  
 Carpinus betulus var. fastigiata.  
 Cephalotaxus Harringtonia var. koraiana.  
 Chamaecyparis Lawsoniana.  
 Chamaecyparis nutkaensis.  
 Juniperus communis var. saccata.  
 Juniperus virginiana (especially var. pyramidalis).  
 Liriodendron Tulipifera var. pyramidalis.  
 Picea (most species).  
 Populus alba var. Boileana.

## COLUMNAR OR NARROW PYRAMIDAL TREES, continued.

Populus nigra var. italica.  
 Quercus pedunculata var. pyramidalis.  
 Robinia pseudacacia var. pyramidalis.  
 Sorbus hybrida.  
 Taxodium distichum (especially var. imbricarium).  
 Taxus baccata var. fastigiata.  
 Thuja.  
 Ulmus campestris var. monumentalis.  
 Ulmus scabra var. fastigiata.

## 9. ROUND-HEADED TREES.

Acer platanoides var. globosum.  
 Æsculus Hippocastanum var. umbraculifera.  
 Catalpa bignonioides var. nana.  
 Fraxinus excelsior var. globosa.  
 Morus alba var. nana.  
 Prunus Mahaleb var. globosa.  
 Robinia Pseudacacia var. umbraculifera.  
 Ulmus campestris var. gracilis.  
 Ulmus campestris var. umbraculifera.

## 10. WEEPING TREES.

Acer saccharinum var. Wieri.  
 Betula alba var. pendula.  
 Crataegus monogyna var. pendula.  
 Fagus sylvatica var. pendula.  
 Fraxinus excelsior var. pendula.  
 Fraxinus parvifolia var. pendula.  
 Gleditsia triacanthos var. pendula.  
 Prunus pendula.  
 Prunus serotina var. pendula.  
 Quercus pedunculata var. Dauvessei.  
 Salix babylonica.  
 Salix blanda.  
 Salix vitellina var. pendula.  
 Sophora japonica var. pendula.  
 Sorbus aucuparia var. pendula.  
 Tilia petiolaris.  
 Ulmus scabra var. pendula.

## 11. CITY TREES. (See also No. 12.)

Ailanthus altissima (pistillate tree).  
 Carpinus.  
 Celtis occidentalis.  
 Crataegus oxyacantha.  
 Fraxinus americana.  
 Fraxinus excelsior.  
 Ginkgo biloba.  
 Gleditsia triacanthos.  
 Platanus orientalis.  
 Populus deltoides.  
 Populus nigra var. italica } (often attacked by borers).  
 Prunus serotina.  
 Robinia Pseudacacia (often attacked by borers).  
 Sophora japonica.  
 Tilia tomentosa.  
 Tilia ulmifolia.  
 Ulmus americana.  
 Ulmus campestris.

## 12. SHADE AND AVENUE TREES.

Besides the trees enumerated under city trees, No. 11 (which are to be recommended as street trees in the cities), the following trees are good avenue subjects:

Acer platanoides.	Quercus alba.
Acer rubrum.	Quercus coccinea.
Acer saccharinum.	Quercus imbricaria.
Acer saccharum.	Quercus palustris.
Æsculus carnea.	Quercus rubra.
Æsculus Hippocastanum.	Quercus phellos.
Catalpa speciosa.	Quercus rubra.
Liquidambar styraciflua.	Tilia americana.
Liriodendron Tulipifera.	Tilia dasystyla.
	Tilia ulmifolia.

## 13. TREES FOR SEASIDE PLANTING.

Ailanthus altissima.	Populus deltoides var. carolinensis.
Crataegus oxyacantha.	Populus tremuloides.
Elæagnus angustifolia.	Quercus rubra.
Hippophaë rhamnoides.	Salix alba.
Juniperus virginiana.	Salix caprea.
Picea alba.	Sassafras.
Pinus nigra.	Tamarix.
Pinus sylvestris.	

## 14. TREES FOR DRY SITUATIONS AND DRY CLIMATES.

Acer campestre.	Pinus divaricata.
Acer ginnala.	Pinus rigida.
Alnus rugosa.	Pinus sylvestris.
Betula pendula.	Quercus coccinea.
Cornus mas.	Quercus Prinus.
Elæagnus angustifolia.	Quercus rubra.
Fraxinus pubescens.	Quercus velutina.
Pteleodendron amurense.	Ulmus effusa.

## 15. TREES FOR WET SOIL.

Acer rubrum.	Picea mariana.
Acer saccharinum.	Pinus rigida.
Alnus glutinosa.	Populus (most species).
Alnus maritima.	Quercus alba.
Betula alba.	Quercus bicolor.
Betula nigra.	Quercus palustris.
Carya laciniosa.	Quercus phellos.
Chamaecyparis thuyoides.	Salix (most species).
Nyssa sylvatica.	Taxodium distichum.
Picea alba.	

ALFRED REHDER.

## Choice of street trees for special regions

## TREES FOR THE EASTERN PART OF THE CONTINENT.

## Street trees for New England and northern New York.

URBAN.	SUBURBAN.
Acer platanoides.	Acer rubrum.
Platanus orientalis.	Acer saccharum.
Quercus rubra.	Fraxinus americana.
Tilia americana.	Platanus occidentalis.
Ulmus americana.	Quercus alba.
	Quercus palustris.

## From New York City and Pennsylvania southward even to Georgia along the mountains.

URBAN.	SUBURBAN.
Acer platanoides.	Acer rubrum.
Ginkgo biloba.	Acer saccharum.
Platanus occidentalis.	Fraxinus americana.
Platanus orientalis.	Liquidambar styraciflua.
Quercus coccinea.	Liriodendron Tulipifera.
Quercus palustris.	Quercus alba.
Quercus rubra.	Quercus bicolor.
Tilia americana.	
Ulmus americana.	

## The coast region from Norfolk southward and along the Gulf of Mexico, except southern Florida.

URBAN.	SUBURBAN.
Liquidambar styraciflua.	Magnolia acuminata.
Quercus laurifolia.	Magnolia grandiflora.
Quercus nigra.	Magnolia tripetala.
Quercus phellos.	Nyssa sylvatica.
Quercus virginiana.	

## North central states.

URBAN.	SUBURBAN.
Celtis occidentalis.	Acer rubrum.
Native oaks.	Acer saccharum.
Tilia americana.	Fraxinus americana.
Ulmus americana.	Platanus occidentalis.

## Add to the above list for points south of Cleveland, Chicago and Omaha.

URBAN.	SUBURBAN.
Acer platanoides.	Liquidambar styraciflua.
Ginkgo biloba.	Liriodendron Tulipifera.
Platanus orientalis.	Platanus occidentalis.
Quercus coccinea.	
Quercus palustris.	
Quercus rubra.	

Most points in northern Alabama, northern Mississippi, southern Arkansas, Oklahoma, and part of Texas back of the coast region are adapted to the trees of both the northern list and the list for the south Atlantic and Gulf coast regions.

F. L. MULFORD.

## Ornamental trees for the middle and southern states.

## Deciduous trees.

*Acer saccharinum* (*A. dasycarpum*) and *A. Negundo*, the latter extensively used for street planting.—*Broussonetia papyrifera*, formerly planted along streets, but objectionable because of the many suckers which they produce, as is also *B. Kazinoki*.—*Cercis canadensis*. Valuable as an early spring-flowering tree.—*Celtis Bungeana*. One of the most distinct trees; an excellent shade tree.—*Catalpa*. Seldom planted South as an ornamental tree, because of the repeated attacks of caterpillars. The latter are frequently used for fish

bait.—*Cladrastis tinctoria*. Very desirable as a flowering lawn tree.—*Cornus florida*. The white-flowering species is among the most attractive of our early spring-blooming trees and is largely used in landscape work. The pink- and red-flowering forms are exceedingly beautiful.—*Crataegus*. Taking into account the various shapes, the foliage and the bright-colored fruit in fall and winter, the best are: *C. Phænopyrum* or Washington thorn, *C. arborescens*, *C. spathulata* and *C. æstivalis* or apple haw.—*Chilopsis saligna*, known as *C. linearis*, is one of the best for dry soils. The typical species produces lilac-colored flowers, but several forms have lately been produced with flowers ranging from light lilac to lilac-purple with yellow stripes inside. A pure white-flowering form is very striking but is of more dwarf habit.—*Diospyros virginiana*. Sometimes planted for shade or for its fruit. Adapts itself to nearly all soils. There are many forms varying both in the foliage and size and shape of fruit.—*Fagus grandifolia* is frequently used for street planting in sandy soils. The red-leaved forms of the European species are of little value South, the purple tint of the foliage fading to a dull green at the approach of warm weather.—*Fraxinus acuminata* and *F. pubescens*. Both thrive best in rich soils and are very desirable for street planting, being seldom attacked by insects.—*Ginkgo* or *Salisbury* is sometimes used for avenues and street planting where a rigid pyramidal tree is required. The foliage is one of its attractions, being shaped like the maidenhair fern.—*Gleditsia triacanthos*. The fertile tree is sometimes planted for its large falcate pods, which are relished by many for the saccharine acidulated pulp. The finely pinnate foliage is very ornamental.—*Halesia tetraptera*. In the middle sections of the South and in rich, dry soils it grows to a small tree, but in the mountain districts in rich soils along the water-courses, trees 40 to 50 feet high are frequently found. Valuable for landscape planting.—*Carya* or *Hicoria*. The pecan is the best southern nut tree and is very largely planted for its nuts. It is often planted in avenues for its beauty.—*Carya myristiciformis* is scarce, but its foliage is more attractive than that of any other species.—*Hovenia dulcis*. The foliage and the fleshy red peduncles in autumn make it an excellent shade and ornamental tree.—*Ilex polycarpa*. A handsome tree when grown in partial shade; the bark blisters in full sun.—*Juglans*. *J. nigra* is one of the most valuable ornamental and economic trees and is extensively planted for avenues. The Persian or English walnut and its many forms are being more largely planted than of old, but are often injured by late spring frosts following a warm period during February. *J. Sieboldiana* is a very ornamental tree and very productive at an early age. *J. cinerea* is suited only to the mountain regions of the South.—*Kalreuteria paniculata*. Very desirable for its pinnate foliage and panicles of yellow flowers, which are succeeded by bladder-like fruits.—*Lagerstramia indica*. The crape myrtle is one of the most characteristic features of southern homes. It has become almost naturalized South. If trained to a single stem, it will form a tree 25 to 30 feet high; otherwise it affects the bush form. It is conspicuous for its shining brown bark and the profusion of its beautifully crimped and fringed flowers, which are produced from April until August. The colors vary from a pale to a dark pink, purplish red, pure white and glowing crimson. No other flowering tree can surpass it in beauty, and by a judicious selection of the various colored flowers a grand effect is produced in landscape work.—*Liriodendron Tulipifera*. One of the most valuable and rapid-growing shade and ornamental trees; thrives best in rich soil. Trees taken from woods transplant badly. They should be grown in nursery and occasionally transplanted until sufficiently large for using in street planting.—*Liquidambar*. A most symmetrical shaped tree; adapts itself to all soil; valuable for street planting. Some trees

assume a deep purple or crimson tint in the foliage during autumn, others a golden yellow.—*Magnolia*. Of the native deciduous species, *M. acuminata* is the most desirable for street and avenue planting. All the species are voracious feeders and thrive best in rich soils. *M. macrophylla*, or umbrella magnolia, seldom grows beyond 25 feet, but is conspicuous for the length and size of its leaves. This tree is called umbrella tree South, whereas this name applies to *M. tripetala* at the North. *M. Fraseri*, ear-leaved magnolia or wahoo of the western North Carolina mountaineers, is also a very ornamental tree. *M. tripetala* is objectionable in gardens owing to the unpleasant odor of its flowers. Few Chinese species, with the exception of *M. hypoleuca*, attain the size of a tree. *M. denudata* and *M. Soulangeana* can be trained to a single stem and made to attain a height of 25 feet. All the other varieties may be classed as shrubs. The flowers are often injured by late spring frosts.—*Melia Azedarach* (Pride of India, Chinaberry). Almost naturalized South. It is of very rapid growth and begins to flower at an early stage. The flowers are delightfully fragrant, with the perfume of the lilac. Extensively planted for shade trees. The umbrella form, known as Texas umbrella, assumes a dense, spreading head with drooping foliage. It is of unique appearance and can be used with great effect in landscape work.—*Morus*. *M. rubra* is frequently planted for shade; it is valuable for its wood, which is of great durability for posts. *M. alba* is naturalized in many sections. A form of *M. rubra* discovered in middle Georgia some years ago and called the Stubbs mulberry, from the discoverer, produces enormous crops of large, rich vinous fruit. This and the Hicks and Downing varieties are often planted for feeding poultry and hogs. They should not be planted near dwellings, owing to the dropping of the fruit.—*Nyssa sylvatica*. Only desirable in landscape work for the brilliant red tint of its autumn foliage.—*Oxydendrum arboreum*. Desirable for its flowers and highly colored autumn foliage.—*Parkinsonia aculeata*. Retoma or horse bean of southern Texas. A small tree with green bark, feathery foliage and yellow flowers. Valuable for shrubberies.—*Paulownia tomentosa*. Rapid-growing. Almost naturalized in some sections of the South. The foliage in young trees is very large. Flowers pale violet, very fragrant, in long panicles; they open before the leaves appear.—*Peach*. There are many ornamental varieties which are exceedingly handsome while in bloom, especially the double-flowering crimson, white and pink; others are desirable for their peculiar growth, as Pyramidalis, which is as erect as a Lombardy poplar. Weeping, willow-leaved, and golden-leaved varieties are interesting.—*Prunus*. Hortulana or Chicasaw plums are sometimes planted for ornament, though commonly for fruit. *P. virginiana* is abundant everywhere but

not valued owing to being usually infested with tent caterpillars. *Prunus Pissardii* is the best purple-leaved tree for the South, as it retains its color during summer.—*Pinckneya pubens*. This very ornamental small tree is seldom seen under cultivation, as it grows naturally in wet and boggy soils.—*Pyrus coronaria*. The crab-apple, a small tree with very fragrant flowers in spring, is excellent for shrubberies.—*Platanus occidentalis*. One of the most desirable trees for street planting.—*Populus*. The variety used most freely for street planting is *P. deltoides* or *P. monilifera*, commonly known in the South as cottonwood. It is of rapid growth and thrives in nearly all soils that are not too arid. All southern nurserymen catalogue the Carolina poplar, but the stock is not always true to name.—*Pterocarya fraxinifolia*, or Caucasian wing-fruited walnut, is a very rapid-growing tree, with spreading branches and pinnate foliage. Very ornamental when

covered with pendulous racemes of small winged nuts, which, however, are of no economic value.—*Quercus*. Nearly

all the species of the middle and eastern states are found more or less abundant in the middle South, but the most valuable purely southern species are as follows: *Q. phellos*, or willow oak, with lanceolate leaves; *Q. aquatica*, or water oak, with leaves almost

perennial, oblong and obtusely lobed. Both are largely planted for streets and shade, as they grow very rapidly and in almost any soil. *Q. falcata*, *Q. laurifolia*, *Q. phellos* and *Q. Muhlenbergii* are desirable. *Q. virginiana*, or live oak, is a very large tree, seldom exceeding 50 feet in height but covering a large circumference. It is native along

the seacoast and adapts itself to inland sections, where it does not attain the great size of the coast region. There is no southern tree, except *Magnolia grandiflora*, that is more admired, especially when planted in avenues.—*Sapindus marginatus*. The globose yellow berries are retained during winter. Berries when boiled produce a saponaceous fluid.—*Stillingia sebifera*. Naturalized on the coast of Georgia and South Carolina. The acuminate rhomboidal leaves give the tree a unique appearance. Requires rich soil and is valuable in landscape work.—*Symplocos tinctoria*. Not common. Should be available for shrubberies.—*Tilia pubescens*. A large tree occasionally found in rich soils along the seacoast. Differs little in general from *T. americana*, but seems to be better suited to the middle South. Very desirable for street planting or shade.—*Toxylon*, or *Maclura*, is naturalized in many sections of the middle South. Grows to a height of 30 feet and the fertile trees are very ornamental when laden with their large, globular fruit. The wood is very lasting when used for posts and takes a beautiful polish.—*Ulmus americana* is perhaps more largely planted for streets and avenues than any other deciduous tree.—*Viburnum prunifolium* (black haw or possum haw). In very rich

355. Avenue of live oaks, Audubon Park, New Orleans.

for fruit. *P. virginiana* is abundant everywhere but

soils sometimes attains a height of 15 to 20 feet. The dark blue berries are retained during winter. Desirable for shrubberies.

#### Broad-leaved evergreen trees.

*Camellia japonica*. Although these magnificent plants are usually seen in bush form, they can be trained to single stems and attain a height of 20 or more feet in the coast region, where they have found a congenial soil and climate. The typical single red variety, a tree of which is growing at Charleston, S. C., and planted in 1808, being the first introduced, is now upwards of 20 feet high. The double-flowering sorts, while usually of vigorous growth, do not attain the size of the single red.—*Cinnamomum Camphora*. In southern Louisiana and middle Florida trees grow to a height of 50 feet; in the middle South they affect the bush form or when trained to single stems exceed 15 to 20 feet. For the extreme South it is recommended for street planting.—*Cyrilla racemiflora*. Specimens are occasionally found on shady banks of streams, where the soil is very rich, that will grow 20 feet high, but the tree form must be secured by pruning. The foliage assumes a bright red or bronze tint in winter.—*Eriobotrya japonica*. Flowers produced in January, and if not frost-killed are followed by a golden yellow plum-like fruit of good flavor. Reaches a height of 20 or more feet in the coast belt.—*Gordonia Lasianthus*. A stately tree found only in shallow swamps or turfy soils. The roots spread almost entirely near or upon the surface of the ground, which makes it difficult to transplant trees taken from the woods. Trees grown from seed in pots are best for planting, but a rich moist soil is necessary to their growth.—*Ilex*. *I. opaca* and *I. Dahoon* are among the most valuable evergreen trees, the former being the best where a large tree is desired. Specimens taken from the woods should not exceed one foot in height, as larger sizes almost always fail in transplanting.—*Ligustrum*. *L. japonicum* often forms a tree 25 feet high. Berries blue-black, retained during winter.—*Magnolia*. *M. grandiflora* is justly considered the glory of southern broad-leaved evergreen trees. There are many forms, based on the size and shape of the leaves and the flowers. The superb white flowers, which are seen from May until August and occasionally upon some trees as late as October, vary from 4 to 12 inches in diameter. Thrives as far north as Washington, D. C. *M. glauca* has white flowers 2 to 3 inches in diameter and delightfully fragrant.—

356. A Norway Spruce.—  
*Picea excelsa*.

*Osmanthus fragrans* var. *ruber* and *O. Aquifolium* var. *ilicifolius*, can be trained to single stem. The flowers of the first are delicately fragrant and produced twice a year.—*Persea carolinensis*. Planted for shade in rich soils in the coast belt.—*Photinia serrulata*, or Chinese evergreen thorn, has white flowers and dark red autumn foliage.—*Prunus carolinensis*. Known south as Carolina Cherry, Caro-

lina laurel, mock orange, etc. One of the most ornamental southern trees.—*Quercus Suber*. Acorns were distributed by the United States Patent Office in 1860, and many large trees are now found in several sections of the South, where they have fruited. Some small plantations are made for the purpose of producing cork. It grows well in comparatively poor and stony soils.—*Sabal Palmetto* is now freely used for street and avenue planting on the coast. It is conspicuous for its tropical appearance. It is not entirely successful further than 40 miles from the seashore.

#### Conifers or narrow-leaved evergreens.

*Abies*. Of this section few specimens are found below the Piedmont region. Occasionally the Norway spruce grows to a moderate size.—*Cedrus Deodara*. An admirable tree and of rapid growth, 40 to 50 feet. *C. atlantica*. 25 to 30 feet.—*Cunninghamia lanceolata*. Foliage resembles an araucaria.—*Cupressus*. *C. sempervirens* has many forms, from the compact, spiral or shaft-like shape to more spreading habit. *C. lusitanica* or cypress of Goa, has numerous forms with foliage of an ashy green and pendulous branches, to others of a more dark tint and rigid form. Of *Chamaecyparis Lawsoniana* there are endless forms, from a compact, erect habit and vivid green foliage to those of open or pendulous shape and with glaucous or golden foliage. *Cupressus funebris* has varied less in its seedlings.—*Juniperus*. The Irish juniper is of fine pyramidal form, and reaches a height of 15 feet. *J. excelsa*, *J. chinensis* and *J. thurifera* differ in the tint of their foliage and are all of tall growth.—*Libocedrus decurrens*. The California arborvitæ, with its graceful feathery foliage and conical shape, is one of the most ornamental of conifers.—*Pinus*. Few of the exotic species are suitable to the South. *Pinus excelsa*, or Bhotan pine, is undoubtedly the best adapted to the middle South of all kinds.—*Retinispora* is a valuable group of Japanese cypress, but with the exception of *R. obtusa*, *R. Fulleri*, *R. plumosa* and *R. squarrosa Veitchii*, all are of dwarf habit.—*Thuja*. The Asiatic section is better adapted to the middle South than the American species. Of the former the best forms are known to nurseries as *Biota pyramidalis* and var. *aurea*, reaching a height of 15 to 18 feet. *B. japonica* var. *filiformis* (*Thuja orientalis*) is a remarkable variety, with thread-like foliage and compact habit to 10 to 12 feet.

In the foregoing list of Coniferæ no mention is made of species or varieties of low or shrub-like growth, such as *Podocarpus*, *Cephalotaxus*, *Thuyopsis*, and *Sciadopitys*, of which there are many good specimens in various parts of the south. Araucarias are also omitted, owing to their liability of failure from extreme heat or other unfavorable climatic conditions. This applies also to *Sequoia*, and *Frenelas* (properly *Callitris*); these frequently make an extraordinarily rapid growth until late in autumn, and are often injured by a cold wave early in winter.

P. J. BERCKMANS.

#### Trees on the Great Plains.

The Plains, lying mostly west of the Missouri River, are not absolutely treeless, as strangers often suppose, but the whole vast area is dotted here and there with small groves, or narrow belts that fringe the borders of the streams. The number of native species, however, is much smaller than in the rich tree flora of the north-eastern United States and Canada. The number of species cultivated for shade and ornament, for a long time, at least, must be relatively small, owing to climatic and other causes. In general, the people of the Plains are necessarily more interested at present in planting trees for profit than for pleasure, but in the older parts are already to be found many fine public parks and private grounds. To a large extent, however, their point of view is that of forestry rather than horticulture.

In studying the forest trees of the Great Plains of central North America, it is found that most of the species have migrated out upon the Plains from the great forest body of the Mississippi Valley. These trees found their way upon the Plains by way of the forests that border the Missouri River and its tributaries. As we pass down the river, along the eastern edge of the Plains, the forest belt becomes larger and larger, until it eventually merges into the great body of forest trees lying on the easterly side of the Mississippi Valley. The principal trees that have come upon the Plains by this route are the common red cedar, papaw, half a dozen willows, one cottonwood, basswood, two or three elms, hackberry, mulberry, three ashes, wild apple, four or more species of hawthorns, junberry, wild cherry, choke cherry, wild plum, coffee bean, honey locust, redbud, sycamore, two species of buckthorns, buckeye, one maple, box elder, sumach, two species of walnuts, five or six hickories, nine or ten oaks, ironwood, blue beech, and one birch. But ten species of trees have come from the Rocky Mountain forests, and these have made much less impression upon the forests of the Plains than those that came from the eastern forests. In this list are the bull-pine, the western red cedar, four species of cottonwoods, the buffalo berry, a maple, and two birches.

Although the present forest area of the Plains is not relatively great, it is large enough to be seriously considered in regard to its preservation. There is danger that with the habit acquired by our people in the thickly wooded parts of the United States of cutting down forest trees wherever found, much of this small forest area will be destroyed. It is much easier to preserve an area of forest growth than to create it anew. First, all forest fires must be kept down. When a mass of woodland adjoins the open prairie, fire-guards should be made so that the fires will not sweep into the forest growth. The greatest destroyer of the forests of the Plains in the past has been fire, as it swept over the prairies into woodland. Second, it is absolutely necessary to keep out certain kinds of stock. Swine, if herded in large numbers, will inevitably destroy the trees. They prevent the growth of small trees, and eventually destroy those of larger growth. Cattle, in large numbers, are equally destructive. In fact, when the attempt is made to preserve uninjured the trees in a forest, it is necessary to keep out stock of all kinds, excepting possibly during limited portions of the year. Third, it is necessary to cut out the trees for use with very great care. A forest should be a permanent crop, and the cuttings should be so made that the forest as a whole is not injured. Trees should be cut here and there in such a way that the young trees which are left have an opportunity for growing into usable timber.

Care should be taken to encourage the tendency to spreading which is so strong in nearly all parts of the Plains. With a little care every present living forest area may be made to extend itself spontaneously, or nearly so. The forest should be effectually inclosed by a fence, placed at some distance from its outer border, leaving a belt of unoccupied land between the trees and the fence. This will grow up with weeds, and mingled with these will be the seedling trees springing from the seeds blown or carried from the forest area. In this way the border of the forest will be gradually extended. This can be helped by plowing up these inclosed belts of land, giving better opportunity for the starting of seedling trees. With the weeds and little trees will spring up low shrubs of various kinds. These need give no trouble, for this is merely Nature's way of taking possession of the soil. Little, if any, cultivation need be given to such a nursery belt, as the weeds which spring up, while unsightly, will serve the useful purpose of sheltering the little trees, and eventually the trees will rise above, and choke them out. Grass, however, forming a tough sod, is harmful to the little trees, far more so than the ordinary weeds.

There are many places in which actual planting must be resorted to. In looking about for a site for the new forest plantation, it must be remembered that the best conditions for tree growth are usually to be found near the natural forests. Where there are natural forests, the planting should be around their borders, so as to extend them in much the same way as indicated in the preceding paragraph in regard to natural spreading. Where there are no natural forests at all, it is necessary to select the more favorable places for planting. Since the natural forests on the Plains occupy the depressions rather than the hilltops or the slopes, this should give

357. A good field elm.

one a hint as to what must be done. Wherever the land slopes into a depression, one may find favorable conditions for growing trees. These depressions, generally called "draws," may be filled with trees, and when once a growth of a few acres is secured it will not be difficult to extend the forest far up the hillside slopes. On the western parts of the Plains similar positions should be taken under the irrigation ditches. In the selection of trees for the formation of forest areas, one should also take a hint from nature. The rule, which is a very excellent one for the plainsman to follow, is to plant on his farm the kinds that he finds in the nearest forest, and to give his planted trees as nearly as possible the same conditions as those under which they grew in the native forest. On the eastern third of the Plains, the walnut, white oak, shellbark hickory, white elm, red elm, hackberry, white ash, wild cherry, catalpa and honey locust are recommended for planting. On the extreme eastern parts bordering the Missouri River, many more kinds can be planted, but as one passes westward toward the borders of the Sand Hill region the list grows smaller. On the central Plains the list is reduced, and also somewhat changed in species. The two elms may be planted, as also the hackberry, the green ash in place of the white ash, wild cherry, honey locust, and in many places the bull-pine. On the western Plains, especially that portion lying west of the main body of the Sand Hills, and having an elevation above the sea of from 3,000 to 4,000 feet, the list is still smaller. The white elm is still included, also the hackberry, the bull-pine, and in many places the red cedar.

The trees mentioned are of the more durable and profitable kinds. But on all parts of the Plains persons must often have quick-growing trees, which soon produce fuel, but which have little, if any, value for other purposes. In the eastern part of the Plains, the black willow, almond willow, common cottonwood, silver maple, and box elder are useful trees for this purpose. One should not condemn the use of these easily grown, soft-wooded trees. A forest is a crop, and there is no reason why a farmer may not plant a more quickly growing crop if he wishes, but he should at the same time plant the more enduring kinds given in the preced-

ing lists. On the central Plains the quickly grown trees may include the same willows and cottonwood and also the box elder. The silver maple will not do well in the greater part of this central region. On the western Plains the list is essentially the same as for the central portion: namely, the willows, cottonwood, and the box elder, to which may be added, here and there, one or more of the western species of cottonwood.

The horticultural point of view is to be considered. About country homes the first trees are usually cottonwood, silver maple and box elder, followed later by green ash and white elm. Very commonly the red cedar is planted with the first-mentioned species, and often Scotch and Austrian pines are added. It must be remembered that the settler's house on the Plains stands in the open instead of being hemmed in by forest trees, as in the eastern parts of the American continent. The settler's problem is to surround his house with trees, not to clear the trees away. In towns and cities the cottonwood, silver maple and box elder are generally the pioneer trees, since they produce a shade sooner than any others, and later these are gradually replaced by

358. *Phoenix canariensis*. One of the most serviceable palms in California.

green ash and white elm. Hackberry, black walnut and buttonwood are occasionally planted with good success. The species which are most largely used for wind-breaks for orchards and other plantations are common cottonwood, willow (a variety of *Salix alba*), silver maple and box elder. The first mentioned, because of its easy propagation, rapid growth and extreme hardiness, is the favorite tree for this purpose. When landscape gardening is attempted, the Scotch and Austrian pines, Norway spruce and red cedar are generally used, and to these are often added one or more species of the Rocky Mountain spruces. The most generally used deciduous tree for this purpose is the white elm (which here attains to a singular beauty of form and foliage), to which are occasionally added bur oak, black walnut and Russian olive (*Eleagnus*), and in proper situations, the white willow. The coniferous trees of greatest value for ornamental purposes on the Plains are the Austrian pine, Scotch pine and red cedar. With proper care these may be grown on all parts of the Plains where water enough to maintain life may be obtained. On the extreme eastern border, the Norway spruce and even the balsam fir have proved valuable. Among deciduous trees the white elm holds first place, followed by the hackberry (which is not so much planted as it deserves) and the green ash.

CHARLES E. BESSEY.

**TREES FOR PLANTING ON THE GREAT PLAINS.** The asterisks (\*) indicate those trees that are not native to the regions.

1. *For the eastern plains.*

*Abies balsamea*.  
*Abies concolor*.  
*Acer platanoides*.  
*Ailanthus altissima*.  
*Carya ovata*.  
*Catalpa speciosa*.  
*Celtis occidentalis*.  
*Fraxinus americana*.  
*Gleditsia triacanthos*.  
*Juglans nigra*.  
*Picea alba*.

*Picea excelsa*\* (Fig. 356).  
*Picea pungens*.  
*Pinus austriaca*.  
*Pinus sylvestris*.  
*Prunus serotina*.  
*Quercus alba*.  
*Robinia Pseudacacia*.  
*Salix vitellina*.  
*Ulmus americana* (Fig. 357).  
*Ulmus fulva*.

and the following quick-growing but temporary trees:

*Acer Negundo*.  
*Acer saccharinum*.  
*Populus Sargentii*.

*Salix amygdaloides*.  
*Salix nigra*.

2. *For the central plains.*

*Catalpa speciosa*.  
*Celtis occidentalis*.  
*Fraxinus lanceolata*.  
*Gleditsia triacanthos*.  
*Picea canadensis*.  
*Pinus divaricata*.

*Pinus scopulorum*.  
*Prunus serotina*.  
*Robinia Pseudacacia*.  
*Ulmus americana*.  
*Ulmus fulva*.

and the following quick-growing but temporary trees:

*Acer Negundo*.  
*Populus Sargentii*.

*Salix amygdaloides*.  
*Salix nigra*.

and in the southern parts:

*Elæagnus angustifolia*.  
*Maclura aurantiaca*, Nutt.

*Pinus austriaca*.  
*Pinus sylvestris*.

also black walnut and bur oak if seed is planted where tree is to stand permanently.

3. *For the high western plains.*

*Celtis occidentalis*.  
*Juniperus scopulorum*.  
*Pinus divaricata*.

*Pinus scopulorum*.  
*Robinia Pseudacacia*.  
*Ulmus americana*.

and the following quick-growing but temporary trees:

*Populus acuminata*.  
*Populus Sargentii*.

*Salix amygdaloides*.  
*Salix nigra*.

and nearer the mountains:

*Acer Negundo*.  
*Acer platanoides*.  
*Elæagnus angustifolia*.  
*Fraxinus lanceolata*.

*Gleditsia triacanthos*.  
*Juglans nigra*.  
*Populus Sargentii*.  
*Tilia americana*.

Seeds or seedlings grown in the region in which they are to be planted are the most reliable. Young trees or seedlings succeed better than older and larger ones. Varieties native in moist climates or in foreign countries should be avoided unless their adaptability has been proved. Young plants, like young animals, are easily killed and must have extra care.

C. L. WATROUS.  
 C. E. BESSEY.

**Trees grown for shade and ornament in California.**

The mild and equable climate of California allows a wide range of available species from which to select trees for shade, ornament and shelter. There is, nevertheless, some considerable variation in the species, which are characteristic of the plantings in different parts of the state, that has arisen from variations in soil and climatic conditions.

On account of the long rainy season, the low humidity of the atmosphere and the relatively high mean, and freedom from low winter minima in temperatures, the trees that thrive best in middle California are those indigenous to the arid and semi-arid warm temperate regions of the globe, e. g., southern Australia, the Mediterranean region, south Africa, northern Mexico and Chile, together with those native species which deserve a place. As one goes into the southern part of the state, some of these species drop out and others markedly

characteristic of arid regions take their place. The reverse of this is true, as one goes north, where many trees of the temperate humid regions also thrive in this state, particularly in the relatively humid climate of the coast, and are offered by our nurserymen.

### I. THE SPECIES HERETOFORE MOST EXTENSIVELY PLANTED IN CALIFORNIA.

The following trees are perhaps the commonest species found in the plantings:

- |                                      |   |
|--------------------------------------|---|
| 1. <i>Eucalyptus globulus</i> .      | 15. <i>Araucaria Bidwillii</i> .        |
| 2. <i>Cupressus macrocarpa</i> .     | 16. <i>Araucaria excelsa</i> .          |
| 3. <i>Pinus radiata</i> .            | 17. <i>Populus deltoides</i> var.       |
| 4. <i>Robinia Pseudacacia</i> .      | <i>carolinensis</i> .                   |
| 5. <i>Acacia melanoxylon</i> .       | 18. <i>Juglans californica</i> and      |
| 6. <i>Schinus Molle</i> .            | <i>species</i> .                        |
| 7. <i>Acacia decurrens</i> var.      | 19. <i>Salix babylonica</i> .           |
| <i>dealbata</i> .                    | 20. <i>Acer saccharinum</i> .           |
| 8. <i>Acacia decurrens</i> var.      | 21. <i>Eucalyptus robusta</i> .         |
| <i>molliis</i> .                     | 22. <i>Eucalyptus viminalis</i> .       |
| 9. <i>Melia Azedarach</i> var.       | 23. <i>Eucalyptus rostrata</i>          |
| <i>umbraculiformis</i> .             | (Fig. 360).                             |
| 10. <i>Phoenix canariensis</i>       | 24. <i>Acer macrophyllum</i> .          |
| (Fig. 358).                          | 25. <i>Pittosporum</i> <i>species</i> . |
| 11. <i>Magnolia grandiflora</i> .    | 26. <i>Cedrus Deodara</i> and           |
| 12. <i>Ulmus racemosa</i> and        | <i>species</i> .                        |
| <i>species</i> .                     | 27. <i>Betula alba</i> .                |
| 13. <i>Cordylina australis</i> (Fig. | 28. <i>Grevillea robusta</i> .          |
| 359) and <i>species</i> .            | 29. <i>Washingtonia filifera</i> .      |
| 14. <i>Acer Negundo</i> , and var.   | 30. <i>Cinnamomum Camphora</i>          |
| <i>californica</i> .                 |   |

### II. TREES BEING MOST EXTENSIVELY PLANTED IN CALIFORNIA AT THE PRESENT TIME.

The following list, arranged in sequence according to the actual number of sales made during the season of 1911-12, is compiled from data furnished by W. B. Clarke, of the California Nursery Company, at Niles. The percentages refer only to the twelve species here enumerated, and not to the total number of trees sold by the nursery, which has a large and varied assortment of species, many of which are more suitable and more effective than those for which there is, at present, the greatest demand.

	Per cent.
<i>Eucalyptus globulus</i> .....	40.8
<i>Cupressus macrocarpa</i> .....	12.0
<i>Platanus orientalis</i> .....	11.4
<i>Eucalyptus rostrata</i> .....	10.2
<i>Populus nigra italica</i> .....	6.2
<i>Pinus radiata</i> .....	5.0
<i>Acacia decurrens dealbata</i> .....	3.5
<i>Acacia melanoxylon</i> .....	3.0
<i>Populus deltoides</i> var. <i>carolinensis</i> .....	2.2
<i>Robinia Pseudacacia</i> var. <i>Decaisneana</i> .....	2.0
<i>Acer saccharinum</i> .....	2.0
<i>Schinus Molle</i> .....	1.7

### III. SELECTIONS FOR SPECIAL PURPOSES.

The following lists are from species now offered in the California trade and are intended to be suggestive only, and not by any means complete. New species and varieties are constantly being added to the nursery stocks, some of which will be found particularly well adapted to certain conditions of climate and soil, and will doubtless replace others now in use.

#### 1. For subtropical effect.

That there is in California strong appreciation of subtropical effects in gardening is shown by the great demand for dracenas and such large-leaved plants as palms, magnolias, bananas and rubber trees. That the effect produced by the planting of such trees so often fails to be satisfactory is largely due to one or both of two causes,—either unsuitable location of the specimens, or choice and association of unsuitable species. To prevent a repetition of the first-named error, the prospective tree planter is recommended to consult the article on Landscape Gardening; and to avoid the second, a selection from the following list is suggested, with the addition of such large-leaved herbaceous plants as cannas, colocasia, cynaras, funkias, *Gunnera scabra*, pampas grass, veratrums, agaves, yuccas, aloes,

*Woodwardia radicans* and *Rodgersia podophylla*, together with such shrubby plants as bamboos, giant reed, the choicer varieties of castor-bean, *Senecio grandifolius*, *Polygonum sachalinense* and *P. Sieboldii*.

#### A. Small trees or tall shrubs.

<i>Acanthopanax ricinifolium</i> .	<i>Erythra armata</i> .
<i>Aralia chinensis</i> .	<i>Musa Ensete</i> .
<i>Aralia chinensis</i> var. <i>mandschurica</i> .	<i>Prunus Laurocerasus</i> .
<i>Aralia spinosa</i> .	<i>Ricinus cambodgensis</i> .
<i>Arundinaria falcata</i> .	<i>Ricinus macrophyllus</i> .
<i>Chamærops humilis</i> .	<i>Ricinus sanguineus</i> .
<i>Dicksonia antarctica</i> .	<i>Ricinus zanzibarensis</i> .
<i>Eriobotrya japonica</i> .	<i>Tetrapanax papyrifera</i> .

#### AA. Larger trees.

<i>Catalpa bignonioides</i> .	<i>Livistonia australis</i> .
<i>Catalpa ovata</i> .	<i>Magnolia grandiflora</i> .
<i>Catalpa speciosa</i> .	<i>Paulownia tomentosa</i> .
<i>Cordylina australis</i> .	<i>Phoenix canariensis</i> .
<i>Cordylina Banksii</i> .	<i>Phoenix dactylifera</i> .
<i>Cordylina indivisa</i> .	<i>Phoenix reclinata</i> .
<i>Cordylina stricta</i> .	<i>Phoenix Roebelenii</i> ( <i>P. humilis</i>
<i>Corynocarpus</i> .	var.)
<i>Erythra edulis</i> .	<i>Phoenix sylvestris</i> .
<i>Eucalyptus calophylla</i> .	<i>Phytolacca dioica</i> .
<i>Eucalyptus ficifolia</i> .	<i>Trachycarpus excelsus</i> .
<i>Ficus Carica</i> .	<i>Tristania conferta</i> .
<i>Ficus macrophylla</i> .	<i>Washingtonia filifera</i> .
<i>Gymnocladus canadensis</i> .	<i>Washingtonia robusta</i> .
<i>Jubæa spectabilis</i> .	

*Eucalyptus globulus* can also be used effectively if cut down periodically when the falcate leaves begin to appear; it will continue to shoot up vigorously from the same root for several years. *E. robusta* is useful for screen purposes if cut down before it becomes straggling. This can also be said for *E. polyanthemus*, *E. rudis*, *E. Risdonii*, and many others. *E. polyanthemus* is certainly more beautiful than *E. globulus* and would not need to be cut down so frequently.

#### 2. Trees with ornamental flowers (for California)

In making the following grouping, arranged according to relative hardiness, it has been impossible to give precise information as to the exact degree of frost-tolerance of the several species, as only meager published data on the subject are to be found.

#### A. Susceptible to light frost.

The following would probably succumb to a temperature of 28° F.:

<i>Eucalyptus calophylla</i> .	<i>Jacaranda ovalifolia</i> .
<i>Eucalyptus ficifolia</i> .	

#### AA. Susceptible to heavy frost.

The following are not likely to stand a temperature of 20° F. Some of them may succumb at 25° F., particularly when young.

<i>Acacia Baileyana</i> .	<i>Acacia salicina</i> , etc.
<i>Acacia cyanophylla</i> .	<i>Bursaria spinosa</i> .
<i>Acacia decurrens</i> var. <i>dealbata</i> .	<i>Eucalyptus cornuta</i> .
<i>Acacia elata</i> .	<i>Eucalyptus corymbosa</i> .
<i>Acacia falcata</i> .	<i>Eucalyptus polyanthemus</i> .
<i>Acacia longifolia</i> .	<i>Eucalyptus sideroxylon</i> var.
<i>Acacia nerifolia</i> .	<i>pallens</i> .
<i>Acacia pendula</i> .	<i>Hymenosporum flavum</i> .

#### AAA. Hardy.

<i>Acacia pycnantha</i> .	<i>Magnolia Soulangeana</i> .
<i>Æsculus carnea</i> .	<i>Magnolia stellata</i> .
<i>Æsculus Hippocastanum</i> .	<i>Paulownia tomentosa</i> .
<i>Albizia Julibrissin</i> .	<i>Prunus Armeniaca</i> (double.-fld.)
<i>Catalpa bignonioides</i> .	<i>Prunus cerasifera</i> var. <i>atro-</i>
<i>Catalpa ovata</i> .	<i>purpurea</i> .
<i>Catalpa speciosa</i> .	<i>Prunus japonica</i> .
<i>Cercis canadensis</i> .	<i>Prunus Persica</i> (white.-fld.,
<i>Cercis Siliquastrum</i> .	double red.-fld., dark.-fld.,
<i>Cratægus mollis</i> .	etc.).
<i>Cratægus monogyna</i> (vars.	<i>Prunus spinosa</i> (double.-fld.).
<i>Paulii</i> , <i>punicea</i> , <i>alba plena</i> ,	<i>Pyrus Halliana</i> .
etc.).	<i>Pyrus ioensis</i> (Bechtel's double
<i>Kœlreuteria paniculata</i> .	crab).
<i>Laburnum vulgare</i> .	<i>Robinia hispida</i> .
<i>Lagunaria Patersonii</i> .	<i>Robinia Pseudacacia</i> and var.
<i>Magnolia acuminata</i> .	<i>rosea</i> .
<i>Magnolia grandiflora</i> .	<i>Sorbus Aucuparia</i> .
<i>Magnolia Kobus</i> .	

## 3. Trees with colored foliage.

## A. Glaucous.

## B. Susceptible to frost (20° F. and perhaps less).

Acacia Baileyana.	Eucalyptus polyanthemus.
Acacia dealbata.	Eucalyptus Risdonii.
Acacia glaucescens.	Eucalyptus sideroxylon var.
Acacia salicina.	pallens.
Cocos australis.	Leucadendron argenteum.
Erythea armata.	Phoenix dactylifera.
Eucalyptus globulus (pollarded to produce suckers).	Washingtonia Sonora.

## BB. Hardy.

Cedrus atlantica var. glauca.	Picea pungens var. glauca.
Cedrus Deodara var. glauca.	Sequoia sempervirens var.
Picea pungens var. cerulea.	glauca.

## AA. Purple or bronze.

## B. Susceptible to 25° F.

Ricinus cambodgensis.	Ricinus communis var. Giosonii
-----------------------	--------------------------------

## BB. Hardy.

Acer platanoides var. Reiten- bachii.	Fagus sylvatica var. purpurea.
Acer platanoides var. Schwed- leri.	Fagus sylvatica var. purpurea Riversii.
Betula alba var. atropurpurea.	Prunus cerasifera var. atro- purpurea.
Cryptomeria japonica var. elegans.	Prunus Persica, var.

## 4. Wide-spreading trees for shade, mostly with rounded outline.

It frequently happens that the owner of a California garden desires a wide-spreading tree in the back or one corner of his domain, under which to swing a hammock on a hot day; such trees are also useful in the school-yard, affording welcome shade in which the children can eat their lunch.

## A. Deciduous, all hardy.

## B. Growth rapid or medium.

## C. Suckers likely to be troublesome.

Populus alba.	Ulmus americana.
Robinia Pseudacacia.	Ulmus racemosa.

## CC. Suckers not troublesome.

## D. Requiring a great deal of water.

Salix babylonica.

## DD. Requiring not much water.

Acer macrophyllum.	Acer saccharinum.
Acer Negundo.	Acer saccharinum var. Wieri.
Acer Negundo var. californicum.	Carya illinoensis (Pecan).
Acer platanoides.	Fraxinus americana.
Acer platanoides var. Reiten- bachii.	Fraxinus velutina.
Acer platanoides var. Schwed- leri.	Quercus lobata.
Acer pseudoplatanus.	Quercus pedunculata.
	Ulmus campestris.

## BB. Growth somewhat slow.

Acer campestre.	Quercus coccinea.
Æsculus carnea.	Quercus Kelloggii.
Æsculus Hippocastanum.	Quercus lobata.
Castanea sativa.	Quercus macrocarpa.
Fagus sylvatica var. purpurea.	Quercus rubra.
Juglans Sieboldiana.	Sophora japonica.
Liriodendron Tulipifera.	Tilia americana.
Melia Azedarach var. umbra- culiformis.	Tilia europæa.
Platanus orientalis.	Ulmus campestris.

## AA. Evergreen.

## B. Growth rapid: trees susceptible to 25° F.

Acacia decurrens dealbata.	Acacia decurrens mollis.
----------------------------	--------------------------

## BB. Growth somewhat slow: trees hardy.

Arbutus Menziesii.	Quercus agrifolia.
Ficus Carica.	Quercus Suber.
Olea europæa.	Schinus Molle.
Pinus Pinea.	

## 5. Ornamental trees affording but little shade.

## A. Outline long or nearly columnar.

## B. Deciduous.

Populus nigra var. italica.	Betula alba.
-----------------------------	--------------

## BB. Evergreen.

Jupressus sempervirens.	Juniperus communis var. hi- bernica.
Cupressus sempervirens var. fastigiata.	Taxus baccata var. fastigiata.

## AA. Outline conical or spiral, usually pointed.

## B. Coniferae, with mostly narrow leaves.

## C. Deciduous: hardy.

Larix decidua.	Taxodium distichum.
Larix leptolepis.	Taxodium mucronatum.

## CC. Evergreen.

## D. Susceptible to severe frost (about 20° F.).

Agathis robusta.	Araucaria Cunninghamii.
Araucaria Bidwillii.	Araucaria excelsa.
Araucaria brasiliana.	Araucaria imbricata.
Araucaria Cookii.	Pinus canariensis.

## DD. Hardy.

Abies balsamea.	Picea excelsa.
Abies cephalonica.	Picea mariana var. Doumetti.
Abies concolor.	Picea torano.
Abies nobilis.	Picea pungens.
Abies Nordmanniana.	Pinus contorta.
Abies Pinsapo.	Pinus Coulteri.
Cedrus atlantica.	Pinus densiflora.
Cedrus Deodara.	Pinus Laricio var. austriaca.
Cedrus Libani.	Pinus monophylla.
Cephalotaxus drupacea.	Pinus Pinaster.
Cephalotaxus Fortunei.	Pinus radiata.
Chamaecyparis Lawsoniana.	Pinus Sabiniana.
Cryptomeria japonica	Pinus sylvestris.
Cryptomeria japonica var. elegans.	Podocarpus Totara.
Cunninghamia sinensis.	Pseudotsuga Douglasii.
Cupressus Goveniana.	Sciadopitys verticillata.
Cupressus macrocarpa.	Sequoia gigantea.
Cupressus guadalupensis.	Sequoia sempervirens.
Libocedrus chilensis.	Taxus baccata.
Libocedrus decurrens.	Thuja gigantea.
Picea ajanensis.	Thuja orientalis.
Picea canadensis.	Thujopsis dolabrata.
Picea Engelmannii.	Torreya californica.
	Torreya nucifera.

## BB. Foliage broad.

## C. Deciduous: hardy.

Betula alba.	Ginkgo biloba.
Betula lenta.	Quercus Cerris.
Betula lutea.	Quercus nigra.
Betula papyracea.	Sorbus Aucuparia.
Betula populifolia.	

## CC. Evergreen.

## D. Susceptible to severe frost (probably 20° F. and even less).

Cinnamomum Camphora.	Grevillea robusta.
Corynocarpus laevigatus.	Scaevola diversifolia.
Cryptocarya Miersii.	Tristania conferta.

## DD. Hardy.

Acacia melanoxylon.	Laurus nobilis.
Cerasus lusitanica.	Pittosporum crassifolium.
Ilex Aquifolium.	Quercus Suber.
Lagunaria Patersonii.	Umbellularia californica.

## AAA. Outline more or less rounded, but trees not as wide-spreading nor as shade-giving as in Class 4.

## B. Deciduous.

## C. Susceptible to frost (25° F.).

Phytolacca dioica.

## CC. Hardy.

Æsculus glabra.	Juglans californica.
Fraxinus americana.	Juglans nigra.
Fraxinus excelsior.	Koeleruteria paniculata.
Fraxinus Ornus.	Paulownia tomentosa.
Gymnocladus canadensis.	Robinia Pseudacacia.

## BB. Evergreen.

## C. Probably susceptible to severe frost (20° F., or less).

Acacia cyanophylla.	Eucalyptus ficifolia.
Alectryon excelsum.	Eucalyptus globulus.
Bursaria spinosa.	Eucalyptus maculata var. cit- riodora.
Eucalyptus calophylla.	Eucalyptus robusta.
Eucalyptus cornuta.	Hymenosporum flavum.
Eucalyptus corymbosa.	Maytenus Boaria.
Eucalyptus corynocalyx.

6. *Trees for streets, avenues and roadsides in California.*

The number of tree species suitable for street planting is limited by the necessarily heavy restrictions, as to height, spread, sewer-penetration and sidewalk-raising, imposed by municipal street departments. In European cities the first-named objections are overcome by means of frequent and systematic pruning to a uniform standard; when this necessity can be obviated by the selection of trees which naturally keep within the desired bounds, the labor of maintaining them in a slightly condition is minimized and the result much more pleasing.

For town streets not more than 60 feet in width, it is important to have trees that will not give too much shade and prevent the rapid drying of the roadway after showers, nor be so tall nor wide-spreading as to obstruct the view and shut out sunshine, rendering the adjacent houses dark, cold and damp. On this account, trees with narrow or pyramidal outline are in many cases preferable to those with wide-spreading habit, and, generally speaking, deciduous trees are more suitable than evergreen, although at the time of losing their leaves they make more litter. Exception may be made in favor of such evergreen species as certain palms and cordylines, some acacias and a few other species mentioned below.

It is not wise to use trees of very rapid growth on town streets; they soon become too large and require frequent trimming, which is usually equivalent to mutilation, and are likely to interfere with sewers.

It cannot be said that street planting in California towns has, in most cases, been satisfactory. In spite of the much larger variety of suitable material than is available in most of the states, there are few examples of good street planting to be met with. In most of the

towns the eye is greeted with a few straggling trees, of which perhaps not more than two are of one kind, recalling F. A. Waugh's apt simile of "nine monstrosously different buttons in a row down the front of a Prince Albert coat." There are many pleasing exceptions, however, although few are entirely satisfactory. The repeated attempts to improve the appearance of a town by planting trees along the streets should be encouraged on every occasion, and the object of this discussion is to render assistance by pointing out how some of the mistakes may be avoided. The unsatisfactory results of street planting, so often met with, can generally be traced to one or all of three causes:

(1) Choice of unsuitable species.

(2) The mixing of several species on the same block and even in front of the same lot.

(3) Crowding of trees.

This last-mentioned source of trouble is perhaps the cause of more failures than the first. When trees are once growing, few persons have the heart to thin out the species for the proper distance apart; finally, a newcomer, without personal feeling in the matter and noting only that there is too much shade and too little light, cuts down the whole row and a gap is left in what may have been a fairly uniform block. Spreading avenue trees of large size should not stand closer than 50 feet apart; smaller trees, on narrower streets, should have 40 feet, unless they are slender species such as cordylines or washingtonias, when 20 feet may be sufficient. As a

rule, one small tree to a 50-foot lot will be found ample; if the whole street is planted uniformly with the same species, and at this same distance, the result will be much more pleasing than if four or five trees are planted in front of every house.

This question of spacing can be determined only by the species in use. If 20 feet is added to the diameter of the spread of the crown, an approximate spacing can be secured. For example, cork elms often attain a 60- or 75-foot spread and should be spaced, accordingly, 80 to 100 feet apart. This advice is given from data gathered in various towns where closer plantings were in order, and have already demonstrated how the air, light and heat are shut off by too crowded plantings.

In towns where the climate is very mild, with few extremes trees are planted only for decorative effect and not for shade,—hence these extreme distances may be used even for species which do not attain great size.

On the other extreme in the interior California valleys, the distances may have to be shortened to allow for the extreme

heat, but trees should never be set so closely that the circulation of air is hindered, except of course for wind-break plantings, which are not found on streets as a rule.

A. *For city and town streets.*B. *Small trees suitable for streets 60 feet wide or less.*C. *Deciduous.*D. *Growth rapid or moderate.*

*Tristania conferta.*  
*Umbellularia californica.*

7. *Trees that have been tried in California but have proved unsatisfactory.*

There are many species that have failed to give satisfaction in some localities because of peculiarities of climate or soil; there are some, also, that have proved unsatisfactory on account of habit; from among these may be mentioned:

*Acacia* species. Nearly all acacias stump-sprout badly, so that for temporary planting they should be avoided. When planted in narrow parkings, they are very likely to raise sidewalks also, but this can be remedied by frequent root-prunings, which they stand admirably.

*Acacia melanoxylon* is generally debarred from the citrus belt as a breeder of scale: when mature it is said to suffer quickly from the effects of drought. In the moister climate of the immediate vicinity of the coast, near San Francisco, however, it proves entirely satisfactory.

*Ailanthus altissima*, has a bad reputation on account of its disagreeable odor, but as this is found only in the staminate trees, it can be avoided by planting none but the pistillate (fruit-bearing) trees.

*Cratægus* species. Of all these species, *C. Oxyacantha* is perhaps the one most commonly used, and through the Santa Clara Valley and Bay regions is disfigured,

in most cases, by sooty mold fungus, resulting from scale infestations. This can of course be remedied, but, in the average case, at considerable more expense than would be warranted.

*Eucalyptus corynocalyx* becomes straggling and unsightly with age.

*Eucalyptus globulus* and, in fact, almost all species of the genus, are frequently debarred by town ordinance from growth within 60 or even 70 feet of a sewer, on account of the remarkable length and penetrating power of their roots.

*Eucalyptus robusta*, a species which is exceedingly handsome as a young tree, has been extensively planted along roadsides and streets in the warmer parts of the state. When mature, it becomes straggling and exceedingly brittle, breaking up in an unsightly way.

*Eucalyptus rudis*. This species has a pendent habit when older that often causes a severe splitting of the crown. As the trees are very picturesque, they are often desirable, provided reasonable attention can be given to prevent this.

*Ficus macrophylla* is injurious to sidewalks.

*Grevillea robusta* has brittle wood and is usually much broken in heavy winds, but can be used with satisfaction if kept well cut back.

*Melia Azedarach* var. *umbraculiformis* is unsatisfactory in the immediate vicinity of the coast; as a sidewalk tree it is exceedingly untidy when losing leaves, and is also very much subject to scale insects.

*Paulownia tomentosa* is sometimes objected to on account of the somewhat untidy appearance of the persistent seed-pods, which require no little labor if all are to be removed after flowering.

*Phoenix dactylifera* and *P. reclinata* both sucker objectionably.

*Populus alba*, *Robinia Pseudacacia* and *Ulmus racemosa* are exceedingly troublesome when used as sidewalk trees on narrow streets; their surface roots often break the cement or asphalt sidewalks, and the suckers come up in the midst of lawns several yards away from the parent tree.

*Schinus Molle* should be avoided in the citrus belt, as it is found to harbor and become a nursery for scale insects. As a street tree it is also unsatisfactory, becoming too large and straggling, and requires too much pruning to keep it within bounds; its large surface roots often break cement and asphalt sidewalks.

The species of *Phoenix* and *Jubæa* should be avoided on account of their low, wide-spreading habit, except for avenues and boulevards where there is no sidewalk or where there is from 20 to 30 feet space between sidewalk and driveway.

#### 8. Trees for alkali soils.

There are many places in those parts of the state that enjoy a high temperature and low rainfall, where the percentage of alkali salts in the soil is too great for the cultivation of most of our ornamental trees, and where it is very important that some shade-producing species be grown.

#### A. Tolerant of strong "black" alkali (sodium carbonate).

The most alkali-tolerant tree of those yet tested is *Kalreuteria paniculata*, a small species 15 to 30 feet high, with feathery, pinnate leaves and ornamental yellow blossoms.

#### AA. Tolerant of medium alkali (chiefly "white" alkali).

*Acacia melanoxylon*.  
*Ailanthus altissima*.  
*Albizia lophantha*.  
*Casuarina equisetifolia*.  
*Eucalyptus amygdalina* var.  
*angustifolia* (apparently the  
least sensitive of the eu-  
calyptus).

*Eucalyptus rostrata* (Fig. 360).  
*Eucalyptus sideroxylon* var.  
*rosea*.  
*Phoenix dactylifera*.  
*Platanus orientalis*.  
*Populus Fremontii*.  
*Quercus lobata*.  
*Robinia Pseudacacia*.

*Acer macrophyllum*.  
*Acer Negundo* var. *californicum*.  
*Cinnamomum Camphora*.

*Gleditsia triacanthos*.  
*Ulmus* species.  
*Washingtonia filifera*.

#### AAAA. Tested and found unsuitable.

Most of those trees of the humid regions, e.g., the eastern states and northern Europe, which have been tried on alkali soils, have been found to suffer and to remain dwarf and stunted. This is particularly true of *Liriodendron Tulipifera*, *Quercus pedunculata* and species of *Tilia*.

Since writing the above, the following additional information on the alkali tolerance of ornamental trees has been secured through the investigations of R. H. Loughridge of the Agricultural Experiment Station at Berkeley, and has been placed at our disposal.

Total amount of salts found in the upper 4 feet of soil in which the following trees were growing, expressed in tons per acre:

	Tons per acre in depth of 4 feet.
<i>Kalreuteria paniculata</i> .....	32
<i>Platanus orientalis</i> .....	21 1/2
<i>Eucalyptus angustifolia</i> .....	20
<i>Eucalyptus angustifolia</i> .....	20
<i>Washingtonia</i> (species not stated) .....	7 1/2
<i>Phoenix dactylifera</i> .....	5
<i>Cinnamomum Camphora</i> .....	3 1/2

JOS. BURTT DAVY.  
B. Y. MORRISON.†

#### ARBOR VITAE: *Thuja*.

**ÁRBUTUS** (ancient Latin name). *Ericaceæ*. Ornamental woody plants grown for their handsome evergreen foliage and for their attractive flowers and fruits.

Trees or shrubs with the bark of the branches and younger sts. smooth, and usually red, exfoliating: lvs. alternate, petioled, serrate or entire: fls. monopetalous, globular or urn-shaped, 5-toothed; stamens 10, included; anthers with a pair of reflexed awns, the cells opening by a terminal pore; ovary 5-, rarely 4-celled, cells with many ovules: fr. a globose, many-seeded, berry-like drupe with mealy flesh, mostly granulose outside.—Twelve species in W. N. and Cent. Amer., S. and W. Eu., Asia Minor, N. Afr., and Canary Isls.

The stems and branches are conspicuous by their red smooth bark peeling off in large thin plates, the evergreen foliage, rather large and usually lustrous flowers, white to red, in terminal panicles followed by attractive red fruits. They are of great decorative value for parks and gardens in warm-temperate regions; especially beautiful when adorned with the clusters of white flowers or bright red berries.

Arbutuses grow best in well-drained soil in somewhat sheltered positions not exposed to dry winds. They are very handsome greenhouse shrubs, thriving well in a sandy compost of peat and leaf soil or light loam.

Propagation is by seeds sown in early spring or in fall, or by cuttings from half-ripened wood in fall, placed in sandy peat soil under glass; they root but slowly. Increased also by budding or grafting, usually veneer-grafting, if seedlings of one of the species can be had for stock. Layers usually take two years to root.

#### A. Panicles short, nodding: lvs. usually serrate.

**Unêdo**, Linn. **STRAWBERRY TREE**. From 8–15 ft.: lvs. cuneate, oblong or oblong-lanceolate, 2–3 in. long, glabrous, green beneath: fls. white or red, ovate: fr. scarlet, warty, 3/4 in. broad. Sept.–Dec. S. Eu., Ireland. L.B.C. 2:123. R.B. 31:36. G.C. III. 14:329. Var. **integerrima**, Sims. Lvs. entire. B.M. 2319. Var. **rûbra**, Ait., and var. **Crôômii**, Hort., have red fls. Gn. 26, p. 506; 33, p. 320. F.S.R. 2, p. 375.—Very beautiful in autumn when the tree bears its large scarlet frs. and at the same time its white or rosy fls. Roots and lvs. astringent.

#### AA. Panicles erect: lvs. usually entire.

**Ménziesii**, Pursh (*A. procera*, Douglas). **MADRONA**. Fig. 361. Occasionally 100 ft. high; trunk with dark

reddish brown bark: lvs. rounded or slightly cordate at the base, oval or oblong, 3-4 in. long, glabrous, glaucous beneath: fls. white, in 5-6-in.-long panicles: fr. bright orange-red,  $\frac{1}{2}$  in. long. Spring. W. N. Amer. B.R. 21: 1753. S.S. 5:231. P.M. 2:147. G.F. 3:515; 5:151. Mn.

361. *Arbutus Menziesii*. ( $\times \frac{1}{2}$ )

3:85. B.M. 8249. R.H. 1893, pp. 149, 150.—The hardest and probably the handsomest species of the genus; it stands many degrees of frost. Fig. 361 is adapted from Pacific Railroad Rept.

**arizónica**, Sarg. (*A. xalapensis* var. *arizónica*, Gray). Fig. 362. Tree, 40-50 ft.: trunk with light gray or nearly white bark: lvs. usually cuneate at the base, oblong-lanceolate,  $1\frac{1}{2}$ -3 in. long, glabrous, pale beneath: fls. white, in loose, broad panicles 2-3 in. long: fr. globose or oblong, dark orange-red. Spring. Ariz. G.F. 4:318 (adapted in Fig. 362). S.S. 5:233.—The contrast between the white bark of the trunk, the red branches, and the pale green foliage makes a very pleasant effect: fr. and fls. are also very decorative.

*A. Andrachne*, Linn. From 10-30 ft.: lvs. oval-oblong, usually entire, yellowish green beneath: fls. yellowish white: fr. bright red. Greece, Orient. B.M. 2024. B.R. 2:113. G.C. III. 4:724. R.H. 1911, p. 307 (habit).—*A. andrachnoides*, Link (*A. Andrachne*  $\times$  Unedo. *A. hybrida*, Ker. *A. serratifolia*, Lodd. *A. Milleri*, Hort. *A. photinifolia*, Hort.). Lvs. serrate: panicles drooping: fls. white. B.R. 8:619. L.B.C. 6:580. G.C. II. 9:211. F. 1879, p. 50.—*A. canariensis*, Lindl. Height 10-30 ft.: lvs. oblong-lanceolate, serrate, glaucous beneath: panicles erect: fls. greenish white. Canary Isls. B.M. 1577.—*A. densiflora*, HBK. Height 20 ft.: lvs. oblong or ovate, serrate, downy beneath: fls. white. Mex.—*A. hybrida*, Ker=*A. arachnoides*.—*A. laurifolia*, Hook.=*A. Menziesii*.—*A. laurifolia*, Lindl.=*A. xalapensis*.—*A. Milleri*, Hort.=*A. andrachnoides*.—*A. mollis*, HBK. Shrub or small tree: lvs. oblong, serrate, pubescent beneath: fls. white, often tinged greenish red. Mex. B.M. 4595.—*A. pilosa*, Grah.=*Perettia pilosa*.—*A. procera*, Douglas=*A. Menziesii*.—*A. serratifolia*, Lodd., not Salisb.=*A. andrachnoides*.—*A. texana*, Buckl.=*A. xalapensis*.—*A. tomentosa*, Pursh=Arctostaphylos tomentosa. *A. Uva-ursi*, Linn.=Arctostaphylos Uva-ursi.—*A. xalapensis*, HBK. (*A. laurifolia*, Lindl.). Height 10-20 ft.: lvs. oval or ovate-lanceolate, entire or crenately serrate, glabrous or downy beneath: fls. reddish: corolla abruptly contracted above the middle. Mex., Texas. S.S. 5:232. B.R. 25:67.

ALFRED REHDER.

**ARBUTUS, TRAILING:** *Epigaea repens*.

**ARCHANGÉLICA** (Greek, *chief angel*, from fancied medicinal virtues). *Umbelliferæ*. GARDEN ANGELICA. A genus of 15-20 species of strong-smelling coarse herbs closely allied to Angelica, but differing in highly technical characters associated with the oil-tubes in the fruit.

**offinàlis**, Hoffm. A European and Asian biennial or perennial, known also as *Angelica Archangelica*;

stout herb, with ternately decompound lvs. and large umbels of small fls.—The sts. and ribs of the lvs. were once blanched and eaten, after the manner of celery, and they are still used in making of sweetmeats. Little known in this country, although it is offered by American dealers. Its chief value to us is its large foliage. Seeds may be sown in the fall as soon as ripe, or the following spring. They are slow to germinate. Root used for its aromatic and carminative properties.

**ARCHONTOPHÆNIX** (Greek, *majestic phoenix*). *Palmææ*, tribe *Arécææ*. Showy and elegant palms, completely spineless, and with tall stout trunks, which are conspicuously ringed by the annular scars of the fallen leaves.

Leaves divaricate, terminal, forming a large crown, pinnately divided; the segms. entire or toothed; in very young specimens the lvs. are undivided or simply bipartite; midrib prominent, the nerves more slender; rachis keeled above, convex beneath, the petiole slightly tomentose, and channeled above: infl. appearing much below the lvs., consisting of 2 long, flattened, ultimately pendent and deciduous spathes, inclosing the short-peduncled and much-branched, pedulous spadices: fls. monœcious, sessile on the branches of the spadix; in male fls. the 8 perianth segms. are unique in the family; female fls. with 3 perianth segms., sometimes more: fr. a drupe, globose or elliptic-globose, containing a single fibrous seed.—There are about 10 species, all natives of the Australian or Malayan region. G.C. II. 22:427.

As *Seaforthia elegans*, the second species is well known to all florists and decorators as one of the most graceful and stately palms in cultivation. Both species have become very popular in California for outdoor cultivation (see G. C. III. 27:109), where the second species fruits, seeds and germinates readily.

362. *Arbutus arizonica*. ( $\times \frac{1}{2}$ )

In the North, they are grown in a temperate house, in a rich soil containing a good percentage of fibrous material and sand mixed with an equal part of rich loam. They require plenty of water.

Propagation is by seeds, which sprout readily in pans or boxes if placed in a warm moist house.

A. *Lf.-segms. whitish underneath.*

**Alexándrae**, H. Wendl. & Drude (*Ptychospérma Alexándrae*, F. Muell.). Trunk 70–80 ft.: lvs. several ft. long; rachis very broad and thick, glabrous or slightly scurfy; segms. numerous, the longer ones  $1\frac{1}{2}$  ft. long,  $\frac{1}{2}$ –1 in. broad, acuminate and entire or slightly notched, green above, ashy glaucous beneath: infl. about 1 ft. long, the fls. greenish yellow: fr. ovoid-globular. Queensland. F.S. 18:1916.—Seldom ripening fr. on plants cult. outdoors in Calif. and rather tender when young.

AA. *Lf.-segms. green on both sides.*

**Cúnninghamii**, H. Wendl. & Drude (*Ptychospérma Cúnninghamii*, H. Wendl. *P. elegans*, Blume. *Scaforthia elegans*, Hook.). Trunk and general habit like the preceding, but the segms. acuminate and entire or scarcely notched: fls. shell-pink, followed by globular berry-like drupes. Queensland and New S. Wales. B.M. 4961, 7345, the first as *Scaforthia elegans*, the second as *Ptychosperma elegans*.—Hardier than the preceding, and fruiting freely in outdoor specimens in Calif.

N. TAYLOR.†

**ÁRCTIUM** (from Greek word for bear, probably alluding to the shaggy bur). *Compositæ*. BURDOCK. A few coarse perennials or biennials of Temp. Eu. and Asia, some of them widely distributed as weeds. Involucre globular and large, with hooked bristles, becoming a bur: receptacle densely setose: pappus deciduous, of short serrulate scales: lvs. alternate, large and soft, whitish beneath: plant not prickly: fls. pinkish or purplish in summer.

**Láppa**, Linn. (*Láppa mājor*, Gaertn.). COMMON BURDOCK. The burdock is a common and despised weed in this country, although it is capable of making an excellent foliage mass and screen. In Japan it is much cult. for its root, which has been greatly thickened and ameliorated, affording a popular vegetable. It is there known as gobo (see Georgeson, A. G. 13, p. 210). Roots collected from plants of the first year's growth are used as an alternative in blood and skin diseases. The seeds and fresh lvs. are used medicinally to a limited extent. *A. minus*, Schk., a European weed, widely naturalized in E. N. Amer. is apt to be confused with *A. Láppa*. N. TAYLOR.†

363. *Arctostaphylos Uva-ursi*. ( $\times \frac{1}{2}$ )

About 20 species in N. and Cent. Amer., 1 species also in N. Eu. and N. Asia. Includes *Comarostaphylis*.

They are handsome evergreen shrubs, though generally with less conspicuous flowers and fruits than those of the allied genus *Arbutus*. Some Central American species, however, as *A. arbutoides*, *A. arguta* and *A. polifolia* are beautiful in flower, and well worth a

364. *Manzanita*.—*Arctostaphylos manzanita*. ( $\times \frac{1}{2}$ )

place in the greenhouse or in the garden in temperate regions; of the American species, *A. Pringlei*, *A. viscida* and *A. bicolor* are some of the handsomest. Only the trailing species are hardy North. For culture, see *Arbutus*.

#### INDEX.

bicolor, 9,	manzanita, 4,	tomentosa, 7.
californica, 2,	nevadensis, 2,	Uva-ursi, 1.
diversifolia, 10,	Pringlei, 8,	viscida, 6.
glauca, 5,	pungens, 3, 4,	

A. *Trailing or creeping: lvs.  $\frac{1}{2}$ –1½ in. long: fls. in short and rather few-fl'd. clusters.*

1. **Uva-ursi**, Spreng. (*Arbutus Uva-ursi*, Linn.). BEARBERRY. Fig. 363. Lvs. obovate-oblong, tapering into the petiole, retuse or obtuse at the apex: fls. small, about  $\frac{1}{4}$  in. long, white tinged with red. Northern hemisphere, in N. Amer. south to Mex. Em. 2:431. Gn. 14:68 (habit).—Hardy trailing evergreen shrub, like the following valuable for covering rocky slopes and sandy banks. Cuttings from mature wood taken late in summer root readily under glass. Lvs. are employed in medicine chiefly for their action on the kidneys and bladder.

2. **nevadensis**, Gray (*A. californica*, Hort.). Lvs. ovate or obovate-lanceolate, abruptly petioled, acute or mucronate at the apex: fls. in short-stalked clusters, white or tinged with red. Calif., in the higher mts. G.W. 13:326 (habit).

AA. *Erect shrubs: lvs. usually 1–2 in. long: fls. in mostly many-fl'd. paniced racemes.*

B. *Lvs. glabrous, rarely minutely pubescent.*  
c. *Pedicels glabrous.*

3. **pungens**, HBK. From 3–10 ft.; glabrous or minutely pubescent: lvs. slender-petioled, oblong-lanceolate or oblong-elliptic, acute, entire, green or glaucescent: fls. in short, umbel-like clusters: fr. glabrous, about  $\frac{1}{4}$  in. broad. Mex., Low. Calif. B.R. 30:17. B.M. 3927.

4. **manzanita**, Parry (*A. pungens*, Authors). Fig. 364. Shrub or small tree, to 30 ft.. lvs. ovate, usually obtuse and mucronulate at the apex, glabrous, dull green: fls. in prolonged paniced racemes: fr. glabrous,  $\frac{1}{4}$ – $\frac{1}{2}$  in. broad. W. N. Amer., from Ore. south. G.F. 4:571. G.C. III. 44:163. B.M. 8128.

cc. *Pedicels glandular.*

5. **glauca**, Lindl. From 8–25 ft.. lvs. oblong or orbicular, obtuse and mucronulate at the apex, glaucescent or pale green: fls. in prolonged paniced racemes; pedi-

**ARCTOSTAPHYLOS** (Greek, bear and grape). *Ericaceæ*. MANZANITA. Ornamental shrubs grown for their evergreen foliage and also for their attractive flowers and fruits.

Shrubs or rarely small trees: lvs. alternate, entire, evergreen: fls. small in terminal often paniced racemes; calyx 4–5-parted, persistent; corolla urceolate, 4–5-toothed; stamens 8 or 10, included; anthers with a pair of awns, the cells opening with a pore; ovary 4–10-celled, 1 ovule in each cell: fr. a red, usually smooth mealy berry or rather drupe with 4–10 coherent nutlets.—

cels glandular: fr. minutely glandular. Calif.—Intro. 1891. Lvs. used medicinally like those of *A. Uva-ursi*.

6. *viscida*, Parry. From 5–15 ft.: lvs. broad-ovate or elliptic, abruptly mucronulate, acute or rounded at the base, glaucous: fls. in slender and spreading, paniced racemes; pedicels viscid; corolla light pink: fr. depressed, about  $\frac{1}{4}$  in. broad, smooth. Ore. to Calif.

BB. Lvs. more or less pubescent.

c. Branchlets usually bristly-hairy: lvs. dull grayish or bluish green above.

7. *tomentosa*, Douglas. From 2–6 ft.: lvs. oblong-lanceolate or ovate, acute, sometimes serrulate, pubescent beneath, pale green: fls. in rather dense and short, usually paniced racemes; pedicels short: fr. puberulous, glabrous at length. W. N. Amer. B.R. 21:1791. B.M. 3320.—The hardest of the erect species.

365. *Arctotis grandis*. ( $\times \frac{1}{3}$ )

8. *Pringlei*, Parry. Shrub: lvs. broad-ovate or elliptic, usually abruptly mucronulate, pubescent, sometimes glabrous at length, glaucous: paniced racemes peduncled, usually leafy at the base, many-fl.; slender pedicels and calyx glandular-pubescent: fr. glandular hispid. Calif., Ariz.

cc. Branchlets tomentose: lvs. bright green and lustrous above.

9. *bicolor*, Gray. From 3–4 ft.: lvs. oblong-oval, acute at both ends, entire and revolute at the margin, glabrous and bright green above, white-tomentose beneath: fls. in nodding, rather dense racemes; pedicels and calyx tomentose; corolla  $\frac{1}{3}$  in. long, rose-colored: fr. smooth. Calif.

10. *diversifolia*, Parry (*Comarostaphylis diversifolia*, Greene). Shrub, 5–15 ft.: lvs. elliptic or ovate to oblong, 1–2½ in. long, acute, cuneate at the base, spinulose-dentate, often revolute at the margin, grayish pubescent or tomentose beneath: racemes terminal, usually several, 1½–4 in. long, tomentose; pedicels slender;

corolla  $\frac{1}{4}$  in. long, light pink: fr. ovoid,  $\frac{1}{4}$  in. long, scarlet. Low. Calif. May, June: fr. in Aug., Sept. Mn. 5:231.

*A. alpina*, Spreng.—*Arctous alpina*.—*A. arbutoides*, Hemsl. Five to 6 ft.: lvs. lanceolate, oblong, ferrugineously pubescent beneath: panicles erect, loose. Guatemala. B.R. 29:30.—*A. arguta*, Zucc. (*A. nitida*, Benth.). Five to 6 ft.: lvs. oblong-lanceolate, serrate, glaucous and glabrous: panicles loose, erect. S. Mex. B.R. 31:32. B.M. 3904 (as *A. nitida*).—*A. californica*, Hort.—*A. nevadensis*.—*A. nitida*, Benth.—*A. arguta*.—*A. polifolia*, HBK. Height 1–3 ft.: lvs. linear-lanceolate, glaucous and puberulous beneath: fls. red, in loose, erect racemes. Mex.

ALFRED REHDER.

**ARCTÔTIS** (Greek for *bear's ear*, alluding to the achene). *Compositæ*. Herbs with long-peduncled heads and more or less white-woolly herbage, of 30 or more African species: achenes grooved, with scale-like pappus: involucre with numerous imbricated scales: receptacle bristly.—Two species, both treated as annuals, are sold in this country. Cultivation simple.

*breviscapa*, Thunb. (*A. leptorhiza* var. *breviscapa*, DC.). Stemless or nearly so (6 in. high), half-hardy, readily prop. from seeds, and to be grown in a warm, sunny place: lvs. usually longer than the scape, incised-dentate: scape hirsute, bearing one large fl. with dark center and orange rays.

*grândis*, Thunb. Fig. 365. A beautiful annual, forming a bushy clump 2–2½ ft. high: lvs. much shorter than the scape, repand dentate: fls. 2½–3 in. diam., white or white and pale violet.—May be the same as *A. stœchadifolia*, Berger.

*A. Gámbletonii*, Hook. f. Ray fls. deep orange-red. Namaqualand, S. Afr. B.M. 7796.

N. TAYLOR.†

**ARCTÔUS** (Greek, *boreal*, referring to its distribution). Syn. *Mairània*. *Ericacææ*. Ornamental flat shrub, rarely cultivated in rockeries for its bright green foliage and scarlet or black fruits in autumn.

Prostrate glabrous shrub: lvs. alternate, serrate, deciduous: fls. in small terminal racemes; calyx 4–5-parted; corolla urceolate with 4–5-toothed recurved limb; stamens 8–10, included, anthers with a pair of short awns, cells opening with a pore; ovary 4–5-celled: fr. a globose juicy drupe with 4–5 separate nutlets.—One circumpolar species.

This is a plant lying flat on the ground, with shreddy bark, thin deciduous leaves clustered toward the end of the branches, small white flowers appearing before or with the leaves, followed by lustrous, black or red fruits. Adapted for rockeries where it will probably succeed best in peaty soil and in a half-shady position. Propagation is by seeds and by cuttings.

*alpinus*, Niedenzu (*Arctostaphylos alpina*, Spreng. *Mairània alpina*, Desv.). Lvs. obovate or oblanceolate, narrowed into the short petiole,  $\frac{1}{2}$ –1½ in. long, reticulate, serrate: fls. 2–4,  $\frac{1}{2}$  in. long, white tinged pinkish or greenish: fr.  $\frac{1}{4}$  in. across, globose, bluish black. N. Amer., N. Eu., and N. Asia. S.E.B. 6:880. B.B. 2:573. M.D.G. 25:138 (habit). Var. *rûber*, Rehd. & Wilson. Fr. bright red, not changing to black. Rocky Mts., W. China.—This variety is handsomer than the type on account of the bright color of the fr.

ALFRED REHDER.

**ARDÍZIA** (*pointed*, alluding to the stamens or corolla-lobes). Including *Icacorea*. *Myrsinacææ*. Trees and shrubs, some of which are grown in their juvenile state as pot subjects, or as outdoor specimens in warm climates.

Flowers white or rose, usually in cymes, with 5-parted (sometimes 4- or 6-parted) rotate corolla, 5 stamens attached to the throat of the corolla, with very large anthers and a 1-seeded drupe the size of a pea: lvs. entire, dentate or crenate, thick and evergreen.—Probably more than 200 species in the tropical and subtropical parts of both hemispheres, one of which (*A. crenulata*) is a popular berry-bearing conservatory

and table plant, and a half-dozen others of which are sometimes seen in collections.

*Ardisia crenulata* is in great demand as a Christmas plant. The other species are seldom seen in this country. They are nearly always propagated from seed, but a plant can be secured more quickly, and better, from a cutting. When plants are over three years old, they often lose their foliage and become "leggy." Good plants can be obtained from the bushy tops by girdling them near the branches, and covering the pieces from which the bark has been removed with wet moss; the moss will be well filled with root in about six weeks, when the tops may be taken off and potted, keeping them in a tight case until they grip the soil. These plants, from which the tops have been removed, are excellent material from which to obtain cuttings, and they will break quite readily if placed in a close, warm atmosphere, about 65°. Cuttings should be taken from young shoots of half-matured wood, and placed in a cutting-bed with a top and bottom temperature of 70°. If these conditions are followed they will root in a month, after which they may be transferred to small pots. Loam, peat and sand in equal parts is the best potting material. As the plant increases in size and vigor, decomposed manure should be added to the mixture, about a fourth part of manure being sufficient. A night temperature of 65° should be maintained for securing the best results.—The advantage of the cutting over the seedling will be apparent, the cutting branching near the pot, whereas the seedling will grow a few inches of stem first. Care should be exercised in selecting the plants from which to propagate, since those grown from seed will vary somewhat in the size and number of berries they produce, and only the best should be selected as stock plants. As soon as the plants show signs of flowering, they should be given more air, and wetting overhead should be avoided until the berries are set. They should at all times be kept in a light position near the glass; during the summer months, however, they should be shaded with cheese-cloth on bright sunny days. About the 1st of October, the berries will be well developed and should be given plenty of sunshine to color them well. The temperature may be lowered to 50° or 55°, as growth is not wanted at this season. Waterings with soot-water will be beneficial, a handful to an ordinary watering-pot. This produces a fine color on the leaves and berries.—The large brown scale is the greatest enemy of this plant; and the best means to keep this in check is to fumigate with cyanide of potassium. Several fumigations will effect a cure. The temperature of the house should never be over 60° when fumigated. (Geo. F. Stewart.)

A. Fls. red or rose-colored.

*crenulata*, Lodd. (*A. crenata*, Sims. *A. crispa*, Hort.). Fig. 366. As cult., a compact and neat shrub, with lance-oblong, wavy-margined, alternate lvs. and drooping clusters of small coral-red, long-lasting, handsome frs: fls. in terminal panicles, sweet-scented. Probably native to E. Indies or China. B.M. 1950. L.B.C. 1:2. Mn. 1:58. A.F. 13:558. Var. *variegata*, Hort., has variegated lvs.

*humilis*, Vahl. Lvs. lance-oblong, shining: frs. shining black. India.

*Oliveri*, Mast. Lvs. nearly sessile, recurved, oblanceolate and acuminate, 6-8 in. long, entire: fls. pink, in large, dense heads, like an ixora, the limb rotate, ½ in. across. Costa Rica. G.C. II. 8:681.—Elegant stove plant.

AA. Fls. white.

*japonica*, Blume. Lvs. short-oblong or somewhat cuneate, whorled, serrate: fls. on red pedicels in drooping racemes: berries white. Dwarf. Japan.—Probably hardy in the N.

*polycéphala*, Wall. Lvs. bright green, red or wine-colored when young, opposite: fr. black. E. Indies.

AAA. Fls. purple or black-dotted.

*Pickeringia*, Torr. & Gray (*Icacorea paniculata*, Sudw.). MARLBERRY. Glabrous, to 24 ft.: lvs. oblanceolate to lance-oblong, entire, narrowed to a petiole: panicle many-flid.; corolla-lobes oval and becoming reflexed: fr. as large as peas, black and shining. E. Fla. Intro. 1891.

*A. umbellata* is offered in this country as coming from India. The *A. umbellata*, Baker (of the botanists), is a Madagascar plant, and it is doubtful whether it is cult. in this country. Species with white fls. are *A. acuminata*, Willd., B.M. 1678; *A. capitata*, Gray: *A. mamillata*, Hance; *A. punctata*, Roxbg.; *A. villosa*, Wall. Species with red or reddish fls. are *A. macrocarpa*, Wall.; *A. paniculata*, Roxbg., B.M. 2364; *A. serrulata*, Swartz; *A. Wallichii*, DC. Recently described ardisias are: *A. gigantifolia*, Stapf., with elliptic lvs. 12-14 in. long and 8 in. broad: fls. small, rose-colored, in long-stalked loose panicle. S. China. *A. Brandneriana*, Linden, dwarf, with green-shaded crenulate lvs. Congo.

L. H. B.

366. *Ardisia crenulata*. (× ½)

ARÈCA (said to be latinized form of Malayan name). *Palmaceæ*, tribe *Arècæ*. A graceful and well-known group of spineless palms, the trunks solitary or forming a ring-like clump.

Leaves at first bipartite, and only after several years forming the beautiful and gracefully pinnate adult lvs., which form large terminal clusters; lfts. slender, lanceolate or linear, acuminate; rachis 3-angled, convex on the back, the upper face and the petiole concave: spadix very much branched, appearing from the lowest lf.-base, and by the falling of this ultimately being separated from the lf.-cluster; spathes 3, 1 inclosing the fls., the other 2 usually bract-like: fls. monœcious, the female solitary, surrounded by numerous slender spikes of male fls. which are fragrant and white, and much smaller than the female: fr. ovoid, orange-colored, surrounded by the persistent, coriaceous perianth.—There are only about 14 species, confined to the Asiatic and Australian tropics, all the 30 or more species usually credited to the genus belonging in *Acanthophœnix*, *Chrysalidocarpus* (*A. lutescens*), *Dictyosperma*, *Euterpe*, *Hyophorbe*, *Kentia* (Howea), *Oncosperma*, *Phœnicophorum* and others. From Pinanga, the most closely related genus, *Areca* is distinguished by having not more than 6 stamens and by the female fls. being much larger than the male.

*Areca* is commercially a very important genus on account of the betel nut (*A. Catechu*). The fibrous spathes and the covering of the fruit are used in packing; the seeds contain a dye, and, most important of all, are the source of the masticatory "betel nut" of the East. Medicinally, their principal use is for expelling tape-

worms. More than seventeen varieties of the nut are known in India alone, where the trade in the nuts (seeds) exceeds \$30,000,000 yearly. It is also used extensively for medicinal purposes.

The cultivation of arecas is not difficult. They must be grown in a tropical house with a day temperature of 75° to 85° and a night temperature of not less than 60°. Young plants thrive in a mixture of peat or leaf-mold and loam, while older plants will do best in a mixture of loam and sand, equal parts, mixed with a liberal amount of well-rotted cow- or horse-manure. Water freely, at least every other day. As young plants, they form beautiful decorations and when old are perhaps the most graceful and delicately foliaged palms in cultivation. G.C. II. 22:427.

367. Areca Catechu.

A. *Sts. solitary and exceeding 40 ft. in adult trees.*

**Catechu**, Linn. **BETEL NUT**. Fig. 367. *St.* solitary, 40–100 ft.; lvs. 4–6 ft., forming a large crown, but with 1 or 2 of the lowest usually pendulous; lfts. numerous, 1–2 ft., upper confluent, quite glabrous: spathe, flattened and, smooth in age, become fibrous when old: fr. 1½–2 in., ovoid, smooth, orange or scarlet. Asia and Malayan Isls.—Frequent in American tropics.

AA. *Sts. usually numerous, often forming a ring, usually not over 25 ft.*

B. *Young growth red: lfts. appearing in bunches of 3.*

**Issemanii**, Hort. Resembles a red-stemmed chrysalidocarpus: young lvs. very dark red, becoming green; fronds slender, arching, with curving pinnae: fls. and fr. unknown. Oceanica (?). R.H. 1898:261. (as *Linosyadix Micholtziana*).

BB. *Young growth green: lfts. not in bunches of 3.*

**Álicea**, F. Muell. *Sts.* several from the same rhizome, 9 ft. or more high, and slender: lvs. 3–6 ft. long; segms. acuminate, several confluent, especially at apex, bright shining green on both sides: fls. paniculate, the panicle coming from between the lvs. Queensland.

**triandra**, Roxbg. Trunk 15–25 ft. high, 1–2½ in. thick, usually several together, and frequently sending out basal offshoots, cylindrical: fronds 4–6 ft. long; segms. with 6 primary nerves about 1 line apart; petiole about 1 ft. long: fls. as in *A. Catechu*: fr. about as large as an olive, orange-scarlet. India.

*A. alba*, Bory=Dietyosperma alba.—*A. Baueri*, Hook. f.=Rhopalostylis Baueri. B.M. 5735.—*A. elegantissima*, Hort. Trade name(?).—*A. furfuracea*, Hort.=Dietyosperma furfuracea.—*A. gigantea*, Hort.=Pinanga ternatensis.—*A. gracilis*, Roxbg.=Pinanga gracilis.—*A. gracilis*, Thouras=Dypsis pinnatifrons.—*A. gracilis*, Giseke=Drymophloeus appendiculatus.—*A. grandiformis*, Hort.=Trade name(?).—*A. lutescens*, Bory=Chrysalidocarpus lutescens.—*A. madagascariensis*, Mart. A rare species, with small trunk and few lvs. Madagascar.=Dypsis madagascariensis.—*A. monostachya*, Mart.=Bacularia monostachya. B.M. 6644.—*A. montana*, Hort. B.M. 3874 (as Euterpe).—*A. Nibung*, Griff.=Oncosperma filamentosum.—*A. oleracea*, Jacq.=Oreodoxa oleracea.—*A. pumila*, Blume=Nenga Wendlandiana. B.M. 6025.—*A. rubra*, Hort.=Dietyosperma rubra.—*A. rubra*, Bory=Acanthopanax rubra.—*A. Sanderiana*, Hort. Trade name(?).—*A. sapida*, Soland.=Rhopalostylis sapida. B.M. 5139.—*A. speciosa*, Hort. Trade name(?).—*A. tigularia*, Jack.=Oncosperma filamentosum.—*A. Verschaffeltii*, Hort.=Hyophorbe Verschaffeltii.

N. TAYLOR.

**AREGÈLIA** (named in honor of the botanist, C. von Regel). *Bromeliaceae*. Epiphytic hothouse plants with the serrate lvs. arranged in a rosette: fls. in a simple

dense head among the inner lvs. of the rosette, which are often colored, violet, blue or white.—A genus of about 25 species, inhabiting Guiana and Brazil. The species below are sometimes referred to *Nidularium*. For cult., see *Billbergia*.

A. *Length of fl. 1¼ in. or less.*

**tristis**, Mez (*Nidularium marmoratum*, Hort., not Morr. *N. triste*, Regel. *Karátas tristis*, Baker). Lvs. 6–12, from 6–12 in. long and half as broad in the middle, green dappled with brown, somewhat scurfy beneath: fl. purple: bract-lvs. narrow-linear: fr. oblong, white.

AA. *Length of fl. 1½ in. or more.*

B. *Lvs. not barred.*

C. *The lvs. densely scaly.*

**Morreniana**, Mez (*Karátas Morreniana*, Ant. *Nidularium Morrenianum*, Makoy). Lvs. many in a dense rosette, with few very minute spines, not striped, densely scurfy beneath: fls. many, dark purple: bract-lvs. linear-lanceolate.

CC. *The lvs. free from scales or nearly so.*

**Carolinæ**, Mez (*Nidularium Carolinæ*, Lem. *N. Meyendorffii*, Regel. *Karátas Carolinæ*, Ant. *Guzmania pica*, Hort. *Billbergia Carolinæ*, Beer. *B. olens*, Hook.). Lvs. several to many, strap-shaped, rather thick, finely spiny-toothed, 12 in. long, bright green on both surfaces, the bract-lvs. bright red: fls. blue-purple, in a short head nestling in the bright lf.-cup. B.M. 5502. I.H. 7:245.

**princeps**, Mez (*Nidularium princeps*, Morr. *N. spectabile*, Hort. *Karátas princeps*, Baker. *K. Meyendorffii*, Ant. *A. princeps*, Mez.). Lvs. 15–20, about 10–12 in. long, broadest at the middle, firm, spiny-toothed, lightly glaucous: fls. numerous, violet-purple, surrounded by about 8–10 oval, bright red bract-lvs.

BB. *Lvs. conspicuously barred on the back.*

**Binotii**, Mez (*Nidularium Binotii*, Regel. *N. Makoyanum*, Regel. *Karátas Binotii*, Ant.). Lvs. 15–20, strong-spiny, scurfy and transversely banded on the back, the inner ones similar in color: fls. many, white—Not to be confounded with *Bromelia Binotii*.

**spectabilis**, Mez (*Karátas spectabilis*, Ant. *Nidularium spectabile*, Moore. *N. eximium*, Hort.). Fig. 368. Lvs. 10–15 in. long, about 1½ in. broad, serrulate, barred on the back, the apex rounded, apiculate, with a red apical spot: fls. milky, pale blue at the apex. Brazil. B.M. 6024.

GEORGE V. NASH.†

368: Aregelia spectabilis. (x1/6)

XI. Arboriculture.—A palm plantation, with *Corypha umbraculifera* in the foreground.

**ARENARIA** (*arena*, sand, where many of the species grow). Including *Alsine*, *Cherleria* and *Moehringia*. *Caryophyllaceæ*. Low herbs, mostly with white flowers, usually forming mats, and suitable for borders, carpets, and lawn clumps; many of them also used for rockwork and alpine gardens; spring- or summer-flowering.

Annual or perennial, with opposite entire, narrow exstipulate lvs.: fls. small, terminal or clustered, or sometimes axillary; sepals 5; petals 4 or 5, entire or slightly notched, sometimes wanting; stamens 10 (rarely 8); styles mostly 3: fr. a small caps., opening by valves as many or twice as many as the styles.—Perhaps 130–150 species, as the genus is here defined, throughout the world but rare in the tropics. Only the perennial species are commonly cult. Of easiest cult. in almost any soil. Prop. by division; also by seeds, and rare species sometimes by cuttings. Many species of arenaria may be found in the collections of alpine-garden and rock-garden fanciers; but the prevailing cult. kinds are accounted for below. Related genera are *Cerastium* and *Stellaria*. Monogr. by F. N. Williams, Journ. Linn. Soc. 33:326 (1897–8).

## INDEX.

aculeata, 16.	grœnlandica, 8.	pinifolia, 13.
aretioides, 4.	juniperifolia, 15.	purpurascens, 2.
balearica, 3.	juniperina, 15.	Rosànii, 12.
cæspitosa, 14.	lanceolata, 6.	sedoides, 1.
Franklinii, 17.	macrophylla, 7.	tetraquetra, 5.
graminifolia, 9.	montana, 11.	véna, 14.
grandiflora, 10.		

A. *Petals usually wanting or rudimentary.*

1. **sedoides**, Froel. (*Cherleria sedoides*, Linn.). Minute green moss-like carpeter, 1 or 2 in. high: fls. unisexual or polygamous, greenish, inconspicuous. Mts., Eu.—A choice rock-cover in alpine gardens. Prop. by division or seeds.

AA. *Petals usually present and prominent.*B. *Fls. purplish.*

2. **purpurascens**, Ramond. Alpine, tufted and decumbent: lvs. ovate-lanceolate, acuminate: fls. on short tomentose pedicels, 2 or 3 on a branch, the purplish corolla exceeded by the sepals. Pyrenees.—A carpeter.

BB. *Fls. white (sometimes purple in No. 16).*C. *Lvs. ovate-oblong or lanceolate.*

3. **balearica**, Linn. Very low (3 in. high), creeping, with small ovate glossy thick and ciliated lvs.: fls. single on long peduncles; sepals erect. Balearic Is., Corsica.—Not hardy in latitude of New York City.

4. **aretioides**, Portens. Densely cespitose, and making a good green carpet: lvs. oblong-lanceolate, obtuse and short-mucronulate, grooved above and 3-nerved beneath: fls. solitary, with 4 sepals.—High Alps.

5. **tetraquetra**, Linn. Carpeter, 3–6 in., pubescent: lvs. ovate, keeled, 4-rowed: fls. in heads, with sepals stiff and ciliate and nearly equaling petals. France.

6. **lanceolata**, All. Cespitose-procumbent, the sts. ascending: lvs. lanceolate, rounded at base, acute, flat, many-nerved below: fls. 1–3, the sepals lanceolate-acute, equaling the petals. High Alps.

7. **macrophylla**, Hook. Sts. decumbent and angled, pubescent: lvs. lanceolate or lance-oblong, mostly acute: peduncles slender, 1–5-flid., the sepals lanceolate-acuminate. Labrador and Vt. to the Pacific. Intro. 1881.

CC. *Lvs. linear or awl-like.*D. *Sepals obtuse.*

8. **grœnlandica**, Spreng. Annual: very low, forming mats, the decumbent or erectish sts. bearing 1–5 fls.: lvs. linear and obtuse,  $\frac{1}{2}$  in. or less long: sepals and petals blunt, the latter sometimes notched. High altitudes and latitudes, but coming to the seacoast in parts of New Eng., and ranging down the mts. to N. C. Intro. 1884.—A neat little alpine.

9. **graminifolia**, Schrad. A foot or less high: lvs. long and filiform, rough-margined: fls. in 3-forked loose pubescent panicles; petals obovate, exceeding calyx. Eu.

DD. *Sepals acute, pointed or even awned.*

E. *Blossoms solitary, or mostly in 2's or 3's.*

10. **grandiflora**, Linn. Fig. 369. Ten in. or less high: lvs. flat-awl-shaped, 3-nerved and ciliate, the radical ones crowded: fls. large, solitary or in about 2's or 3's, long-stalked. Eu.—Runs into many forms.

11. **montana**, Linn. Smaller: lvs. linear or nearly so: fls. large, solitary, very long-stalked; sepals acuminate, less than the corolla. S. W. Eu.

12. **Rosànii**, Tenore. (*Alsine Rosànii*, Fenzl). Low (1–2 in.): lvs. linear-lanceolate and mucronate, hairy, striate: sts. erect, hirsute, about 3-flid.: fls. white, with obovate petals and striate longer sepals. Italy.

EE. *Blossoms 5–7 (or more) together.*

13. **pinifolia**, Bieb. (*Alsine pinifolia* var. *gracilis*, Fenzl). Cespitose, the branches ascending: lvs. narrowly awl-shaped or bristle-like, often curved: fls. large, in 5–7-flid. corymb, the pedicels equaling the calyx or shorter; sepals linear, hairy, 3-nerved: petals obovate-oblong, exceeding calyx. Asia Minor.—A dwarf compact plant with small pine-like foliage which becomes rosulate on sterile shoots, producing many pure white fls.; an attractive edging and rockery plant.

14. **véna**, Linn. (*Alsine véna*, Bartl.). Dwarf, 1–3 in. high: lvs. linear-subulate, flat, strongly 3-nerved, erect: fls. on filiform peduncles, with strongly 3-nerved sepals. Eu. and Rocky Mts.—Excellent little rock plant. Var. *cæspitosa*, Hort., is a compact, leafy form, making dense moss-like masses; all summer.

15. **juniperina**, Linn. (*Alsine juniperina*, Fenzl. *A. juniperifolia*, Hort.?). Cespitose, nodes often swollen: sts. simple, bearing clusters: lvs. awl-like, mucronate, keeled, about 1-nerved, often recurved and persisting: fls. with lanceolate-acuminate 3-nerved sepals, and longer linear-cuneate white petals. E. Eu. and Asia Minor.—Variable.

16. **aculeata**, Wats. Sts. 4–6 in. high: lvs. stiff and sharp, glaucous: fls. fascicled, white, but often purple. W. Amer. Intro. 1889.

17. **Franklinii**, Douglas. Sts. 3–5 in. high, nearly or quite glabrous: lvs. in 3–6 pairs, narrow-subulate, sharp-pointed: fls. in dense cymes at the top of the st. W. Amer. Intro. 1881.

L. H. B.

**ARÉNGA** (derivation unknown). *Palmaceæ*, tribe *Arécææ*. Tall, usually spineless palms with a thickish, ringed trunk, the upper part of which, and the leaf-stalks are often covered with long black fibers.

369. *Arenaria grandiflora*. ( $\times \frac{1}{3}$ )

Leaves pinnate, the lfts. regularly placed on the rachis, sometimes confluent at their bases, the jagged or cut-off appearance of the lfts. peculiar to this genus and Caryota among the horticultural palms, the margin irregularly toothed above the middle; the lvs. paler beneath than above; petiole flattish or convex; fls. monocious, numerous, and with 2 or more bracts beneath each sessile fl.; spadix 6-10 ft. long in some species, usually smaller, coming from among the lvs. and developing downwards; when the last fl.-cluster reaches maturity some at

least of the species die, notably *A. saccharifera*: fr. the size of an apple and somewhat resembling it, containing 2 or 3 oblong and usually dark brown seeds. G.C. II. 22:522.

Arengas are graceful palms, all natives of tropical Asia and Australia, and so far as known are of only eight species. *A. saccharifera* is an important economic plant in India, the black fiber at the leaf-bases known as gomuta fiber being widely used for filters and in the caulking of ships. The sap yields "arenga sugar" after the plant is ten to twelve years old. For culture, see *Areca*.

*Arenga saccharifera*, in a young state, is surpassed in beauty by most palms. Specimens eight to ten years old, however, show their characteristics well, and from that period till they begin to flower (which they do from the top of the stem downwards in the axils of the leaves), they are among the most striking subjects for high and roomy conservatories. The temperature should not be allowed to fall below 55° F. during the coldest weather. (Oliver.)

A. Trunks at least 20 ft. or more.

*saccharifera*, Labill. Trunk 20-40 ft. high; lvs. very many, frequently 20-28; petioles smooth; lfts. 115, on each side, fasciculate, in 4's or 5's, linear-ensiform, 3-5 ft. long, 1- or 2-auricled at the base, the lower auricle the longer, 2-lobed or variously dentate at the apex, white or silvery beneath: branches of the spadix long, fastigate, pendulous: male fls. purple, 1 in. long. Malaya.

*obtusifolia*, Mart. Trunk 20-30 ft. high, 1-1½ ft. thick: fronds 9-13, 12-16 ft. long; petiole thickly spiny, especially on the margins, scarcely more than 1 ft. long; segms. 1½ in. apart, 2-3 ft. long, 1½-2 in. wide, alternate, lanceolate-linear, unequally acutely dentate, attenuate, 2-auricled at the base, the lower auricle the larger, glaucous beneath: branches of the spadix short, lax, nodding. Java.

AA. Trunks not over 10 ft.

Engleri, Becc. About 5 ft. tall; lvs. numerous, with a great many lfts. about 16 in. long and 1 in. wide, much constricted at the base and irregularly toothed at the apex: infl. much branched, borne among the lvs., not more than 1½ ft. long; fr. about ¾ in. diam. Formosa.—Not as yet common in this country, but interesting among arengas for its small size.

*A. Borrètti*, Hort., reported from E. Indies, is a name frequently appearing in hort. literature, not certainly referable.

N. TAYLOR.†

**ARETHUSA** (the nymph *Arethusa*). *Orchidaceæ*. Handsome terrestrial tuberous orchids.

Scapes leafless or with a single lf. 1- to few-fl.; fl. wapping, the sepals and petals nearly alike, arching over

the column; lip erect, narrow, entire, adnate to the base of the elongated erect column, and produced into a short spur.—Three species, 2 in N. Amer. and 1 in Japan.

*bulbosa*, Linn. Fig. 370. A very pretty hardy orchid, 8-10 in., with one linear, nerved lf. and a bright rose-pink fl. on an erect scape, the lip recurved and bearded. Bogs, N. C., N. and W.; not common. May, June. Mn. 5:141.—Requires a moist and shady, cool situation and open, porous soil. A shady nook on north slope of rockery, where it can be watered in dry weather, is an ideal place. Prop. is by the solid bulbs.

*A. sinénsis*, Rolfe. A terrestrial tuberous herb 4-9 in. high; fls. white and red. W. China. B.M. 7935.

GEORGE V. NASH.†

ARËTIA: *Douglasia*.

**ARGEMONE** (Greek name for an eye disease for which a plant was reputed a remedy). *Papaveraceæ*. ARGEMONY. Prickly garden annuals, grown for the showy yellow, white or purplish poppy-like flowers.

Coarse herbs with yellow juice and sometimes with spotted lvs.: fls. large, short-lived; sepals 2 or 3; petals 4-6; stigmas 6 or less, radiate, sessile or nearly so: pod oblong or ellipsoid, prickly or bristly, opening at top by 3-6 valves.—About 10 species of N. and S. Amer., cult. as annuals, although sometimes biennial or even perennial. Argemonies are easy to manage from seeds sown where the plants are to stand, or transplanted from pots. They need a light soil and full sunny exposure. Monogr. by Fedde, Engler's Pflanzenreich, hft. 40 (1909).

A. Fls. yellow or yellowish.

*mexicana*, Linn. (*A. speciosa*, Hort.). PRICKLY POPPY. Fig. 371. A moderately prickly-stemmed herb, 1-2 ft. high, sprawling, glaucous: lvs. coarsely sinuate-pinnatifid; fls. sessile or nearly so, the petals obovate and an inch or less long, orange or lemon-colored, to

371. *Argemone mexicana*. ( $\times \frac{1}{2}$ )

2½ in. across when expanded. Trop. Amer., but naturalized in eastern and southern states and in many parts of the world. B.M. 243.—Not much used in this country for medicinal purposes. The plant is said to possess emetic, cathartic, anodyne and narcotic properties; the oil from the seeds acts as a mild cathartic. Var. *ochroleuca*, Lindl. Petals yellowish white, and style longer. Texas. B.R. 1343.

370. *Arethusa bulbosa*. ( $\times \frac{1}{2}$ )

AA. Fls. white (rarely purple).

**grandiflora**, Sweet. Fig. 372. Glabrous and glaucous, 1-3 ft. high, almost destitute of prickles, stout: lvs. sinuate-pinnatifid, the lobes only weakly spinescent, white-veined: bracts scattered along the fl. branches:

372. *Argemone grandiflora*. ( $\times \frac{1}{2}$ )

fls. 3-6 near together, 4 in. across: caps.-valves scarcely crested. S. W. Mex. B.R. 1264. L.B.C. 16:1546. B.M. 3073.—Very showy.

**platyceras**, Link & Otto. Robust,  $1\frac{1}{2}$ -4 ft., very spiny, the lvs. glaucous: lvs. sinuate-pinnatifid, spiny: fl.-bracts aggregated below the fls.; petals truncate, large, white (rarely purple), the fls. 2 in. or more across: caps.-valves crested or spiny. Var. **hispida**, Prain (*A. hispida*, Gray). Petals rounded; sepals and caps. densely prickly: plant hispid. Var. **hispido-rosea**, Fedde. Petals rounded, rose or rosy white; sepals narrow, sparsely prickly. Var. **Huntemánii**, Fedde. Petals rounded, white: plant stout.—The species is very variable and widely distributed in N. and S. Amer. Likely to appear in cult. in several forms; all of them have thick and densely prickly caps.-valves.

**álba**, Lestib. (*A. mexicana* var. *albiflora*, DC.). Slender, 1-3 ft., somewhat glaucous: lvs. glabrous, pinnate-lobed and sinuate, the lobes oblong-acute, spiny toothed: fls. solitary or 2-3 together, on naked peduncles, 3 in. across, white; petals oblong, narrowed at base, truncate at top. Southern states and south. B.M. 2342 (as *A. albiflora*).—Sparingly run wild. Caps.-valves thin, reticulate spiny. L. H. B.

**ARGYRÆIA** (silvery, referring to the under side of the lvs.). *Convolvulacæ*. SILVER WEED. Asiatic tender climbers allied to *Ipomœa*, sometimes grown in the open.

Lvs. usually large, silvery, tomentose or villous beneath: cymes usually few-flid.; corolla campanulate; sepals 5.—They require too much room before flowering to be popular in Amer. *A. cuneata* is one of the dwarfest and most floriferous kinds. Prop. by cuttings or seeds, the former over bottom heat. About 25 species.

**tiliæfolia**, Wight (*Rhexia tiliæfolia*, Hort.). Fls. white, violet or rose-purple, widely funnelform: lvs. ovate-cordate, 2-3 in. diam., shortly acuminate or obtuse. Prop. is from seeds. E. Indies.—Intro. 1890 by Peter Henderson & Co.

**cuneata**, Ker-Gawl. Two to 5 ft.: st. downy: fls. large, bright but deep purple, on hairy peduncles which are shorter than the lvs.: lvs. obovate-cuneate, emarginate, glabrate. E. Indies. B.R.: 661.

*A. Pierreana*, Hort. (?). Corolla funnel-shaped, white tinted with rose. Tonquin. R. H. 1906:560. See p. 3566. N. TAYLOR.†

ARIA: *Sorbus*.

**ARIOCÁRPUS** (*Aria-like fruit*). *Cactacæ*. Top-shaped succulent desert plants, mostly buried in the ground, the broad aerial part covered with angular tubercles bearing no spines: fls. from the center of the plant, large, white or pink: fr. small, naked; seeds black, roughened.—A genus of 6 or 7 species confined to Cent. Mex., except a single species in S. W. Texas. A very distinct genus, easily distinguished from *Mamillaria* by its tubercles.

A. Upper surface of tubercle with a broad and deep wool-bearing longitudinal groove, which widens below.

**fissuratus**, Schum. (*Anhalonium Engelmännii*, Lem.). LIVING ROCK. The flat tubercle-covered top 2-5 in. across, tapering below into a thick root; tubercles imbricated and appressed, triangular in outline,  $\frac{1}{2}$ -1 in. long and about as wide at base, the upper surface fissured in bands, the outer ones forming an elevated margin: fls. central, about 1 in. long and broad, shading from whitish to rose. On limestone hills in the "Great Bend" region of the Rio Grande in Texas, and extending into Mex. I.H. 16, p. 73, and fig. Contr. Nat. Herb. 13, pl. 62.

**Llódii**, Rose. Fig. 373. Plant body with rounded top, 4 in. or more in diam.: tubercles imbricated,  $\frac{1}{2}$  in. broad at base, the upper portion rounded, obtuse, broader than thick, the whole surface fissured, but not in definite bands: fls. purple, about  $1\frac{1}{2}$  in. long; petals broad, apiculate. This species differs from *A. fissuratus* in shape and surface of tubercles, in its round top, and more southern range. Cent. Mex. Contr. Nat. Herb. 13, pl. 63.

**Kotschubeyanus**, Schum. (*A. sulcatus*, Schum.). Plants nearly concealed by the ground, often less than 1 in. broad at top, with a deep thick root: fl.-tube nearly  $\frac{1}{2}$  in. long; petals  $\frac{1}{2}$  in. long, rose-pink. Cent. Mex.—Much smaller than the last two. Only recently re-intro. into cult. A very distinct species. *A. McDowellii*, Haage & Schmidt, is the same or a near species.

AA. Upper surface of tubercle not grooved.

**retusus**, Scheidw. (*Anhalonium prismaticum*, Lem.). The flat top 3-8 in. across: tubercles imbricate, but squarrose-spreading, sharply triangular-pyramidal and very acute, with a sharp, cartilaginous tip, which usually disappears with age and leaves the older tubercles blunt or retuse,  $\frac{3}{4}$ -1 in. long and about as wide at base, the upper surface almost plane and smooth, except that it is more or less pulverulent, and often bears a small tomentose tuft just behind the claw-like tip: fls. rose-color. Mts. of Mex. —*A. trigonum*, Schum. and *A. furfuraceus*, Thompson, are similar species sometimes in cult. J. N. ROSE.

**ARISÆMA** (Greek-made name, of no particular significance). *Aracæ*. INDIAN TUR-NIP. DRAGON ARUM. Odd hooded aroids, sometimes grown in hardy borders and some species as pot-plants.

About 60 widely distributed herbs, with

373. *Ariocarpus Lloydii*. ( $\times \frac{1}{4}$ )

tuberous roots, and a spathe rolled in or convolute about the spadix below, and often arched over it: fls. unisexual, the pistillate on the lower part of the spadix, and each consisting of a 1-loculed ovary, and generally ripening into a showy berry. Some species are native, and several of them are hardy in the open; others are cult. under cover, as recommended for *Arum* (which see). Monogr. by Engler in De Candolle's *Monographiæ Phanerogamarum*, Vol. II.

A. Lfts. 7-11.

**Dracóntium**, Schott. DRAGON-ROOT. Sending up a solitary lf. 1-2 ft. high, pedately divided into oblong-lanceolate pointed lfts.: spadix long-pointed and projecting beyond the greenish spathe: scape much shorter than the lf. Low grounds in E. Amer.—Occasionally grown in borders and rock-work.

374. Jack-in-the-Pulpit, *Arisæma triphyllum*. ( $\times \frac{1}{4}$ )

AA. Lfts. 3.

**triphyllum**, Torr.

JACK-IN-THE-PULPIT. INDIAN TURNIP. Fig. 374. Usually dioecious: lvs. usually 2, with ovate or elliptic-ovate lfts.: spadix club-shaped and covered by the arching purplish spathe. Common

in woods. V. 14:179.—Tuber or corm flattish and large, very acrid, often employed as a domestic remedy. Berries red and showy, ripening in early summer. Planted in a moist, shady place, the lvs. remain until fall; but in exposed places they die down early in summer. This and the last are very interesting native plants of easy cult., prop. by tubers and by seeds.

**fimbriatum**, Mast. FRINGED CALLA. Lf. solitary, the petiole a ft. or less high, sheathed below; lfts. broad-ovate and acuminate, short-stalked: scape as long as the petiole, bearing a large, purple-limbed, white-streaked, long-pointed spathe: spadix ending in a long and gracefully drooping, feather-like appendage. E. Indies. G.C. II. 22:689; III. 15:763. B.M. 7150. Mn. 8, p. 59. G. 25:626.—A handsome and striking pot-plant, blooming in summer. Grows in rich soil. Dry off the tuber when the lvs. turn yellow after flowering, and keep dry in sand or earth until spring.

Other species are: *A. anomalum*, Hemsl. Lfts. 3, broad-ovate, acuminate: spathe small, purplish and streaked, arching over the short spadix: suggests *A. triphyllum*. Malaya. B.M. 7211. —*A. concinnum*, Schott. Lf. solitary, with 10 or more lfts.: spathe colored, tailed. India. B.M. 5914. —*A. curvatum*, Hook. = *A. tortuosum*. —*A. Fargèsii*, Bouchet. Spathe striped longitudinally with broad purple-brown bands alternating with bands of silvery white. W. China. —*A. flavum*, Schott. Lvs. pedate: spathe green to yellow. Himalaya. B.M. 7700. —*A. galeatum*, N. E. Br. Lf. solitary, with 3 lfts.: spathe purple inside. India. B.M. 6457. —*A. Griffithii*, Schott. Lvs. 2; lfts. 3, nearly orbicular: spathe very large with a spreading and wrinkled limb several inches broad, and rich purple with green veins. India. B.M. 6491.—One of the handsomest of all arisæmas. —*A. japonicum*, Blume. Lvs. pedate: spathe green, white striped. B.M. 7910. —*A. nepenthoides*, Mort. Lf. pedate, of 5 narrow lfts.: spathe auricled. India. B.M. 6446. —*A. ringens*, Schott. Lfts. 3, ovate-acuminate: spathe purple, arched. Japan. Perhaps hardy in the open. Gn. 37, p. 577. G. 17:182. —*A. Sieboldii*, De Vriese. = *A. ringens*. —*A. speciosum*, Mort. Lfts. 3: spathe large and very dark purple; spadix with a very long, string-like tip. India. Gn. 37:576. B.M. 5964. G.C. II. 12:585. —*A. tortuosum*, Schott. Lvs. usually 2, with several or many lfts.: spathe purple outside; spadix long-tailed but erectish, greenish. India. B.M. 5931 (as *A. curvatum*). —*A. utile*, Hook. Lvs. 2, with 3 crenate lfts.: spathe reddish, green-ribbed; spadix purple: tubers eaten by natives

in India. B.M. 6474. —*A. viridiflorum*, Franch., has recently been offered in Eu., from China. It has pedate lvs., and a striped spathe. —*A. Wrayi*, Hemsl. Lf. solitary, pedate, the lfts. lanceolate: spathe green or whitish; spadix slender, recurved. India. B.M. 7105.

L. H. B.

**ARISÆRUM** (old Greek name). *Araceæ*. Three or four variable species of arum-like plants of the Mediterranean region. Differs from *Arisæma*, its nearest ally, in having the margins of the spathe connate rather than convolute, and in other technical characters. For culture, see *Arum*.

**vulgare**, Targ. (*Arum Arisærum*, Linn.). A foot high: lvs. cordate or somewhat hastate, long-stalked: spathe purple, incurved at the top.—Has many forms and names. Can be grown in the open with protection.

*A. proboscideum*, Savi. Lvs. hastate; scape less than half the petiole: spathe 1-1  $\frac{1}{4}$  in. long, pale gray, with a long olive tail 5-6 in., the mouth of spathe small, olive-purple. Italy. B.M. 6634. G.W. 5, p. 512.

GEORGE V. NASH.†

**ARISTËA** (name refers to the stiff leaf-points). *Iridacææ*. Mostly blue-flowered spring- or summer-blooming greenhouse herbs or sub-shrubs, and grown in the open far south.

Leaves distichous in basal rosettes, those on the st. alternate: fls. clustered in spikes, not lasting; the perianth with a short tube and oblong, spreading, nearly equal segms. that twist up spirally after flowering; stamens short-stalked, borne on the throat of perianth-tube: fr. an oblong or cylindrical 3-valved caps.—About 30 species in Afr. Of easy cult. Prop. by seeds and division. Not showy.

**Écklonii**, Baker. Herb, 1  $\frac{1}{2}$  ft.: lvs. linear but not rigid, 18 in. or less long: fls. in many clusters that form a loose panicle with a flattened rachis; limb of blue perianth  $\frac{1}{2}$  in. long: caps. cylindrical, less than 1 in. long. Cape Colony.—Reported in Calif., where it is said to make dense dark green clumps, with *Sisyrinchium*-like fls. in spring.

**fruticosa**, Pers. (*Nivènia fruticosa*, Baker). Dwarf shrub: st.-lvs. linear, 2 in. or less long: fls. in a single cluster; perianth blue, the tube  $\frac{1}{2}$  in. long. Cape Colony.

L. H. B.

**ARISTOLÒCHIA** (named for supposed medicinal virtues). *Aristolochiaceæ*. BIRTHWORT. Perennial herbs or shrubs, many climbing, remarkable for the very odd-shaped flowers, some species grown in the open, but most of them cultivated as odd glass-house subjects.

The corolla is wanting, but the calyx is corolla-like, tubular, mostly variously bent, and commonly tumid above the ovary and contracted at the mouth, superior; stamens commonly 6, short and adnate to the style, which is fleshy and lobed: fr. a naked 6-valved caps.; seeds flat.—About 180 species of warm

375. *Aristolochia macrophylla*. ( $\times \frac{1}{6}$ )

and temperate regions throughout the earth; mostly woody twiners. Many species are evergreen. The tender species are cult. for the strikingly irregular and grotesque fls. The fls. are usually fetid in odor, often very disagreeable. Many species are grown in botanic gardens and in the collections of fanciers, but those usually cult. or planted are to be found in the treatment which follows.

These plants are mostly climbing vines, *A. macro-*

*phylla* being perhaps the best known vine for shade purposes. It is vigorous and of rapid growth, and has never been known to be attacked by fungoid or insect enemies. For covering outbuildings quickly it has no equal, owing to the heavy growth of foliage and its adaptability to any situation. The flowers are peculiar in shape, giving rise to the popular name, Dutchman's pipe. These are inconspicuous, however, compared with the tropical species of this genus. In contrast with the foregoing, *A. grandiflora* var. *Sturtevantii* has gigantic flowers with a tail sometimes 3 feet long. This species must be cultivated under glass and is most suitable for large structures as the odor when in bloom beggars description, it being such that flies have been known to be deceived, thinking its origin was due to putridity. There are other fine species for indoor culture as *A. brasiliensis* and *A. Goldieana*. These are best propagated from cuttings taken from well-matured wood in early spring or at pruning time. A rich soil is desirable and preference is given to planting the roots in a border or bed that they may be trained up rafters or pillars of warmhouses. Pot culture does not give good results. Another very pretty species is *A. elegans*. This is not odorous, can easily be procured from seeds, which are freely produced under cultivation. It will bloom the first year under glass, and may be cut back to give light to other plants in winter. The outdoor *A. macrophylla* (often known as *A. Sipo*) produces good seed; this seems to be the only way to increase it as hardwood cuttings do not root readily. (E. O. Orpet.)

376. Flowers of Dutchman's Pipe, *Aristolochia macrophylla*, showing the ovary at a, and the swelling of the calyx-tube at b. (×%)

Sipo, 3.  
Sturtevantii, 11.  
tomentosa, 4.  
triangularis, 7.  
tricaudata, 10.

## A. Plant not climbing, herbaceous.

1. *Serpentaria*, Linn. VIRGINIA SNAKEROOT. Height 2 ft. or less, pubescent, with short rootstocks and aromatic roots: lvs. ovate or oblong, cordate or halberd-form, acuminate: fls. near the root, solitary, S-shaped, much enlarged above the ovary, greenish. E. U. S.—Occasionally cult. Roots used in medicine. Reputed remedy for snake-bites. Var. *hastata*, Duch. Lvs. narrow, sagittate or hastate. Southeastern states.

2. *Clematidis*, Linn. Two ft. or less tall, glabrous: lvs. reniform-pointed, ciliate on the margins: fls. axillary and clustered, straight, greenish. Eu.—Rarely cult., and occasionally escaped.

## AA. Plant twining, mostly woody.

## B. Cult. in the open.

3. *macrophylla*, Lam. (*A. Sipo*, L'Her.). DUTCHMAN'S PIPE. PIPE VINE. Figs. 375, 376, 377. Very tall, twining, glabrous: lvs. very large, broadly reniform or rounded, becoming glabrous: fls. solitary or 2 or 3 together in the axils, U-shaped, enlarged above the ovary, with a 3-lobed, spreading flat limb, purplish. Eastern states. B.M. 534. Gng. 1:53. G.F. 5:509 (habit).—An excellent vine for porches, the great lvs. affording a dense shade.

4. *tomentosa*, Sims. Much like the last, but very tomentose: lvs. less rounded: fls. yellow, with reflexed

lobes, the closed orifice purple. N. C. to Ill. and S. B.M. 1369.

5. *californica*, Torr. Silky pubescent, 6–10 ft.: lvs. ovate-cordate, 2–4 in. long, obtuse or acutish, short-petioled: fls. U-shaped, little contracted at the throat, the limb 2-lobed, with the upper lip of 2 broad, obtuse lobes and a thickening on the inner side. Calif.

6. *moupinensis*, Franch. Branches slender, densely silky, becoming smoothish: lvs. cordate, 5 in. or less long, hairy above, grayish pubescent beneath, the petiole about  $2\frac{1}{2}$  in. long: fls. solitary on axillary peduncles, the tube  $1\frac{1}{2}$  in. long, abruptly curved so that the blossom appears U-shaped as it hangs, pale green outside and yellowish inside, the limb obliquely 3-lobed,  $1\frac{1}{4}$  in. across, yellowish and purple-marked. From the Moupin region of W. China. B.M. 8325.—A rapid grower, reaching 15 ft. in one season. A good pillar and post plant, hardy in England. Allied to *A. Kaempferi* (see supplementary list).

7. *triangularis*, Cham. Glabrous: lvs. triangular-acute, 3-nerved, pellucid-punctate, the petioles prehensile, the blade 4 in. long by 3 in. broad: fls. solitary, ovoid-inflated at base and then making a sharp angle, the tube funnelform and the limb small and truncate and not large, purple-spotted. Brazil.—A climber reported in S. Calif.

8. *argentina*, Griseb. Herbaceous, glabrous; st. angular-sulcate: lvs. cordate-deltoid, obtuse, pedately 7-nerved: fls. solitary on axillary peduncles, glabrous without and somewhat puberulent within, the tube ovoid at base, bent, the parts of limb broadly ovate and obtuse. S. Amer. Reported in S. Calif.

BB. Cult. in greenhouse or warmhouse.

c. Fl.-limb of 2 narrow divergent lobes.

9. *ridicula*, N. E. Br. Very slender, stiff-hairy throughout: lvs. round-reniform, cordate: fls. axillary and solitary, 2 in. long aside from the limb, with a long sac at the base of the tube, pale yellow with dull purple veining; limb of 2 spreading, deflexed, narrow lobes, glandular, reminding one of donkeys' ears. Brazil. B.M. 6934. G.C. II. 26:361.

cc. Fl.-limb of 3 narrow lobes.

10. *tricaudata*, Lem. Lvs. 5–8 in. long, oblong-acuminate, rugose, ciliate: fls. solitary; tube short and somewhat inflated at the rounded base, suddenly bent; limb wide and concave, maroon-red outside and very dark purple-brown inside, produced into tails 4 in. long. Mex. I.H. 14:522. R.B. 20:37. B.M. 6067.—A fine species of shrubby habit, producing quantities of fls. all over the older parts of the growths, down to the base of the old st. A striking plant when well grown under sunny conditions in a temp. of 50–55° F.

ccc. Fl.-limb 2-lipped, the lips unlike and one of them usually ample and flowing: fls. large.

D. Blossoms with one or more long hanging tails.

11. *grandiflora*, Swartz (*A. gigas*, Lindl.). PELICAN-FLOWER. SWAN-FLOWER. GOOSE-FLOWER. DUCK-FLOWER. Figs. 378, 379. Downy climbing shrub: lvs. cordate-acuminate; peduncles striate, exceeding the petiole, 1-fld.: the fl.-bud is "bent like a siphon in the tube, so as to resemble the body and neck of a bird, while the limb, in that state, resembles the head and beak thrown back upon the body, as a pelican when that bird is at rest, whence

377. Longitudinal section of flower of Dutchman's Pipe, showing the ovary, and the short column of stamens at q. (×1)

the name" (Hook. in B.M., vol. 74): the great expanded cordate-ovate limb several inches across, wavy-margined, purple-blotched and veined, terminating in a long and slender ciliated tail: strong-scented. Var. *Stürtevantii*, W. Wats., is the form chiefly known in cult., being very large-flid., often 20 in. diam., and with a tail 3 ft. or more long. W. Indies, Cent. and S. Amer. B.M. 4368-9. B.R. 28:60. F.S. 4:351-2. G.F. 3:597-599 (adapted in Fig. 379). A.F. 10:157. G.C. III. 19:73. Gng. 3:23. Gn. 50:378. Var. *Hookeri*, Duch. (*A. gigantea*, Hook.), is glabrous, inodorous, with a short-tailed fl. B.M. 4221.

DD. Blossoms not tailed, although perhaps bearing long more or less erect point-appendages.

12. *Goidieana*, Hook. Whole plant dying down to a large fleshy rootstock: glabrous: lvs. ovate-cordate or triangular-cordate, acuminate, the base deeply cut: fls. very large, greenish outside but brown-veined and blotched inside, the lower part of the tube straightish and 8 in. long, the upper part sharply bent over and a foot long, with a funnel-shaped, spreading limb a foot or more across, and indistinctly 3-lobed, each lobe terminated by slender appendages; stamens 24. W. Afr. B.M. 5672. G.C. III. 7:521; 21:337. G.M. 33:286.

13. *brasiliensis*, Mart. & Zucc. Glabrous: lvs. cordate-reniform, obtuse, with deep sinus at base: peduncle 8-10 in. long, 1-flid.: fl. very large, dingy yellow, with marks and reticulations of purple, the limb strongly 2-lipped; tube strongly bent, purple inside; upper lip 4 in. long, violet within, hairy; lower lip not longer than the upper, 5-7 in. wide. Var. *macrophylla*, Duch. (*A. ornithocéphala*, Hook.). Lvs. large: upper lip 5 in. long, lanceolate-acuminate, projecting from the inflated headlike tube like the long beak of a bird; lower lip on a stalk 2 in. long, then expanding into a flattened, wavy, beautifully marked limb 4 in. long and 4-6 in. across. Brazil. B.M. 4120. Gn. 45, p. 289.—A most odd and interesting species, not infrequent in fine establishments.

14. *élegans*, Mast. CALICO FLOWER. Slender, glabrous, the fls. borne on the pendulous young wood: lvs. long-stalked, reniform-cordate, 2-3 in. across, with wide sinus and rounded basal lobes, the tip obtuse: fls. solitary, long-stalked, the tube yellow-green, 1½ in. long, the limb cordate-circular, 3 in. across, purple and white blotched, white on the exterior, the eye yellow: not strong-smelling. Brazil. G.C. II. 24:301; III. 22:123. B.M. 6909.—A small-flid. and graceful, free-blooming species. A most desirable decorative climber for a warm greenhouse of 55° F. but does not thrive so well in a stove. It is entirely devoid of the unpleasant odor which is characteristic of the fls. of this genus. In Fla. it self-sows freely; and the hanging basket-like frs. are very attractive.

15. *cymbifera*, Mart. & Zucc. (*A. labiata*, Sims). Glabrous: st. striate: lvs. reniform, obtuse and deeply cut at the base, pedately 7-9-nerved, long-stalked: fls. long-stalked, 8-10 in. long, strongly 2-lipped; the upper lip short and lanceolate, acute or acuminate; the lower lip (which, by position of fl. may seem to be the upper) very large, dilated at base, and produced into a long, boat-shaped (whence the name, from *cymba*, a boat)

usually 2-lobed projection; fl. creamy white, marked and blotched with maroon. Brazil. B.M. 2545. P.M. 6:53 (as *A. hyperborea*, Paxt.).

*A. altissima*, Desf. Fls. 2 in. or less long, brownish. Sicily and Algeria. B.M. 6586.—Would probably be hardy with protection in the middle states.—*A. angustica*, Jacq. Lvs. long-cordate: fls. small, 1-2 in. long, with a long-pointed limb. Colombia. B.M. 4361. F.S. 4:344.—*A. barbata*, Jacq. Lvs. oblong and cordate: fls. 2½ in., purple. Venezuela. B.M. 5869.—*A. caudata*, Booth=*A. macroura*.—*A. ciliata*, Hook., and *A. ciliata*, Benth.=*A. fimbriata*.—*A. clypeata*, Lindl. & André. Lvs. triangular-ovate, pointed: fls. with a large, oval, purple-spotted, tailless limb. S. Amer. I.H. 17:40. B.M. 7512.—*A. Duchartrei*, André=*A. Ruiziana*.—*A. fimbriata*, Cham. A free-flowering greenhouse species: lvs. small, cordate-orbicular: fls. small, the little limb glandular-ciliate. Brazil. B.M. 3756 (as *A. ciliata*).—*A. hians*, Willd. Lvs. round-cordate: fls. bronze-green, with lobed limb and a hairy beak. Venezuela. B.M. 7073. Allied to *A. brasiliensis*.—*A. Kämpferi*, Willd. Tall-climbing: lvs. ovate-cordate or hastate, variable: fls. solitary, tomentose, with narrow rim, yellow outside, purple inside. Japan. Probably hardy in the N.—*A. longicaudata*, Mast. Lvs. ovate and cordate: fls. cream-colored with purple markings, with a large sac-like tube, hairy at the throat, with no expanded limb but a very long tail. S. Amer. G.C. III. 8:493.—*A. longifolia*, Champ. Branches climbing, from a woody rootstock: lvs. thick, linear-lanceolate: fls. U-shaped, with a 2-lobed purple limb 2½ in. across. Hong Kong. B.M. 6884.—*A. macroura*, Gomez. Lvs. reniform, lobed: fl. dark maroon, 6-spurred, the lip with a twisted cusp. Brazil. B.M. 3769 (as *A. caudata*).—*A. macroura* × *brasiliensis*, a garden hybrid.—*A. odoratissima*, Linn. Lvs. cordat-ovate: fl. solitary, purple, sweet. Jamaica. —*A. pónica*, Linn. Erect or ascending from a globose rootstock: lvs. large, broadly ovate: fls. very large, curved, greenish purple, ill-smelling. Asia Minor.—*A. ringens*, Vahl. Lvs. round-reniform: fl. 7-10 in. long, green marked with dark purple, hairy inside, with 2 long lips, one of which has a much-expanded limb. Brazil. B.M. 5700.—*A. Ruiziana*, Duch. Lvs. reniform-cordate: fls. with tube 1 in. or less long, the cordate-ovate limb 3 in. across, and brown-spotted. Brazil. B.M. 6880 and G.C. 1868:516 (as *A. Duchartrei*).—*A. sacata*, Wall. Lvs. long-ovate: fls. small, U-shaped, with a very narrow rim (suggesting the Dutchman's pipe), red. India. B.M. 3640.—*A. Sälpinx*, Mast. Lvs. ovate-lanceolate: fls. small, with a trumpet-shaped, somewhat 2-lipped mouth, purplish. Paraguay. G.C. II. 26:457.—*A. unguifolia*, Mast. Lvs. 3-lobed: fls. small, brownish and reddish, with a ciliate, tongue-like lip. Borneo. G.C. II. 14:117. B.M. 7424.—*A. Westlandii*, Hemsl. Lvs. oblong-lanceolate: fl. pendulous, with a spreading purple-marked limb 5 or 6 in. across. China. B.M. 7011. A greenhouse climber producing its fls. on the old parts of the plant near the ground.

L. H. B.

**ARISTOTELIA** (after the Greek philosopher Aristotle). *Elaeocarpaceæ*. Woody plants sometimes grown in the open in warm countries.

Leaves evergreen, nearly opposite, entire or toothed: fls. polygamous; sepals 4-5, valvate; petals of the same number: berries small, edible.—A genus of 7 species of trees and shrubs from the southern hemisphere, allied to *Elaeocarpus*. Prop. by ripened cuttings, under bell-jar or closed frame.

378.  
*Aristolochia grandiflora*,  
var.

379. *Aristolochia grandiflora*. (×8)

**racemosa**, Hook. f. NEW ZEALAND WINEBERRY. Small tree, 20 ft.: lvs. glossy, ovate or cordate-ovate, thin and membranous: fls. white in many-fld. panicked racemes. New Zeal.—Cult. somewhat in S. Calif.

**Mâcqui**, L'Her. Shrub, to 7 ft.: lvs. almost opposite, dentate, smooth, shining, oblong and acute at the apex: fls. inconspicuous, greenish, axillary. Chile.—Grown for its foliage. A variegated form, less hardy than the type, is known. Occasionally found in botanical and other collections, particularly in Calif. N. TAYLOR.†

**ARMENIACA**: *Prunus*.

**ARMÈRIA** (an old Latin name). *Plumbaginaceæ*. SEA PINK. THRIFT. Small perennial herbs, with rosettes of narrow evergreen leaves on the ground, planted along borders and walks, used for continuous low edgings and in rock-gardens; sometimes grown as pot-plants.

Scape naked, simple, 2–12 in. high, on which is borne a compact head of pink, lilac or white fls., the head being subtended by small bracts, forming a kind of involucre; fls. with plaited funnel-shaped dry calyx, the lobes pointed; 5 petals nearly or quite distinct and tapering at the base; 5 stamens opposite the corolla parts; styles 5, hairy below the middle: fr. a utricle inclosed in the calyx.—About 50 species in Eu., W. Asia, N. Afr. and 1 in N. Amer., much confused.

Armerias are of easiest culture, being hardy and free growers. Propagation is by division of the stools; also by seeds.

A. *Calyx-tube usually pilose all over.*

**vulgâris**, Willd. (*A. maritima*, Willd.). COMMON THRIFT. Fig. 380. Lvs. linear, 1-nerved, somewhat obtuse, glabrous or slightly ciliate: scape low, somewhat villose; calyx-tube about the length of the pedicel and decurrent on it, the limb nearly equal to the tube, with very short ovate, blunt or aristate lobes. Eu. and Amer., along the seacoast. Var. **alba**, Hort. White. Var. **rûbra**, Hort. Fls. dark rose-red. Var. **purpurea**, Hort. Purple-red. Var. **Laucheana**, Voss. Light rose-color. Var. **grandiflora**, Hort. Large-fld., light rose-red. Var. **splendens**, Hort. Bright pink. *A. argentea*, Hort., is perhaps another form, with small white fls.; also a white-lyd. form.

**sibirica**, Turcz. Lvs. linear, 1-nerved, obtuse, glabrous: scape rather taller, thicker; calyx-tube longer than pedicel, the limb about length of tube, with triangular, short-mucronate lobes; involucre brown; fls. white. Siberia.

**júncea**, Girard (*A. setacea*, Delile). Outer lvs. of rosette narrow-linear and subdentate, the inner ones longer and filiform: head small, with pale involucre, the pedicel much shorter than the calyx-tube; calyx-limb short, the lobes ovate-obtuse and aristate; fls. pink. Eu.

AA. *Calyx-tube glabrous, or pilose only on the ridges.*

B. *Lvs. elliptic-lanceolate or broader.*

**latifolia**, Willd. (*A. cephalotes*, Link & Hoffm., not Hook.). Glabrous and glaucous: lvs. broad-oblong, 5–7-nerved, the margin remotely denticulate: head large, the involucre dry; calyx-limb long, with very small or no lobes and long teeth; fls. bright pink. S. Eu. B.M. 7313. P.M. 11:79 (as *Statice Pseudo-armeria*).—*A. formosa*, Hort., probably belongs here.

**mauritanica**, Wallr. (*A. cephalotes*, Hook., not Link & Hoffm.). Lvs. broad-spatulate or elliptic-lanceolate, 3–5-nerved, glaucous green, the margin scarious-white: heads large (2–3 in. across), the involucre brownish, the calyx short-toothed and aristate; fls. pink. Eu., Algeria.

BB. *Lvs. linear-lanceolate or narrower.*

**alpina**, Willd. Glabrous: lvs. linear-lanceolate; equaling the scape, 1-nerved or obscurely 3-nerved: head large, the involucre pale brown; pedicels shorter than

calyx-tube, the tube equaling the oblong long-aristate lobes; fls. deep rose. Mts., Eu.

**purpurea**, Koch. Lvs. linear, long, 1-nerved, blunt: outer involucre-scales mostly blunt, the inner very blunt and weak: pedicels as long as calyx-tube, limb equaling the tube, and the lobes ovate-aristate; purple. Cent. Eu.

**plantaginæa**, Willd. Glabrous: lvs. linear-lanceolate, 3–7-nerved, acute or acuminate: scape tall; head dense and globular, the involucre white; pedicels as long as calyx-tube, the lobes ovate and long-aristate and as long as tube; pink. Cent. and S. Eu. Var. **leucantha**, Boiss. (*A. dianthoides*, Hornem. & Spreng.), has white fls.

**argyrocephala**, Wallr. (*A. undulata*, Boiss.). Glabrous: outer lvs. in rosette, short and lanceolate or linear-lanceolate and 3-nerved and often sinuate, the inner ones linear or setaceous and 1–3-nerved: head large, the involucre white; pedicel nearly as long as calyx-tube, the calyx-limb with long-triangular aristate lobes; fls. white, showy. Greece. L. H. B.†

**ARMERIÁSTRUM**: *Acantholimon*.

**ARNATTO**: *Biza*.

**ARNÈBIA** (Arabic name). *Boraginaceæ*. Annual or perennial hispid herbs, grown as flower-garden or border subjects.

Erect or diffuse: root sometimes yielding red tint: lvs. alternate: fls. yellow or violet, in racemes or cymes, the color changing with the age of the blossom; corolla slender-tubed, with 5 obtuse lobes, the throat devoid of scales; stamens included; style usually bifid: fr. normally of 4 erect nutlets.—A dozen species in Asia and N. Afr. of easy cult. in gardens.

**echioides**, DC. (*Macrotomia echioides*, Boiss.). PROPHET-FLOWER. Hardy perennial, 3–12 in. high, short-hairy, with spreading, obovate-oblong lvs.: fls. in a scorpioid raceme or spike, yellow, with purple spots, fading to pure yellow. Caucasus, Armenia, etc. B. M.

4409. G.C. II. 11:689.—Blooms in spring. In full sun or in rather dry ground, it is difficult to keep this charming plant in a healthy condition; partial shade is essential to its welfare. One can grow luxuriant specimens on the northern slope of a rockery or close to a building on the east or north side. Prop. by seeds, division, or by root-cuttings.

**cornûta**, Fisch. & Mey. ARABIAN PRIMROSE. Annual, 2 ft., bushy: lvs. lanceolate or linear-oblong, pointed: fls.  $\frac{3}{4}$  in. across, yellow and black-spotted, changing to maroon and then to yellow. Orient. G.C. III. 7:52. J.H. III. 31:29. A.F. 5:400. A.G. 11:181 (1890).—An attractive and not very common annual, easily grown in the open.

*A. Griffithii*, Boiss. Annual, 9–12 in.: lvs. narrow-oblong, obtuse, ciliate: fls. long-tubed, with a black spot in each sinus. India. B.M. 5266.—*A. macrothyrsa*, Stapf. Perennial, 1 to nearly 2 ft.: fls. yellow in dense thyrses. Armenia. L. H. B.†

**ÁRNICA** (ancient name). *Compósitæ*. Perennial herbs sometimes seen in borders or rockeries.

With clustered root-lvs. and opposite st.-lvs. and large, long-peduncled yellow heads: involucre bracts all equal,

380. *Armeria vulgaris*. (X  $\frac{1}{4}$ )

thin, in a single, rarely double series. Native to Eu., Asia, and N. Amer., about 10 species.—Tincture of the European *A. montana* is used in medicine. Grown mostly as alpine or in rockwork; some species also grow well in the common border. Prop. by division, and rarely by seeds.

381. *Arnica montana*. ( $\times \frac{1}{2}$ )

st. leafy, strict. Rocky Mts. and W.

*montana*, Linn. MOUNTAIN TOBACCO. MOUNTAIN SNUFF. Fig. 381. A foot high, the st. sparsely hairy: radical lvs. oblong-lanceolate, glabrous and entire: heads 3-4, large. Eu. B.M. 1749. J.H. III. 34:441. Gn. 24, p. 394. G. 29:215.—The best known species in cultivation and can be grown in the open border, but none of the arnicas is common in American gardens.

*A. Clusii* = *Doronicum Clusii*.

L. H. B.  
N. TAYLOR.†

**ARONIA** (modification of *Aria*, a subgenus of the allied genus *Sorbus*). *Rosaceæ*. CHOKEBERRY. Ornamental shrubs grown for their attractive white flowers and for their handsome fruits, and also for the bright autumnal tints of the foliage.

Low plants: lvs. deciduous, short-petioled, finely and crenately serrate, glandular on the midrib above, convolute in bud; fls. in small corymbs, white; calyx 5-lobed, petals 5, spreading; stamens numerous; ovary 5-celled, woolly at the top, with 5 styles united at the base, the carpels connate but partly free on their ventral suture: fr. a small pome, flesh without grit-cells, top hemispherical.—Three closely related species in E. N. Amer. Closely related to *Sorbus*, which is easily distinguished by the sharply or doubly serrate, often pinnate lvs. folded in bud and without glands above, by the usually 2-3-celled ovary with the carpels connate on their ventral suture, otherwise often partly free, and by the conical top of the fr.: quite distinct in general

appearance and habit and suggesting more an affinity with *Amelanchier*.

The aronias are small shrubs with simple deciduous leaves turning bright red in autumn and with white flowers in small corymbs followed by berry-like, red, purple or black fruit. Well adapted for borders of shrubberies and quite hardy North. *A. melanocarpa* is handsomest in foliage and bloom, particularly the var. *grandifolia*; its fruit ripens in August, but soon shrivels and drops, while *A. atropurpurea* and *A. arbutifolia* have showier and usually more numerous fruits; those of *A. atropurpurea* ripen in early September and shrivel at the beginning of the winter, while those of the last-named species ripen later and remain plump and bright far into the winter.

They prefer moist situations, but *A. melanocarpa* also grows well on drier and rocky soil. Propagation is by seeds sown in fall or stratified; also by suckers and layers, or by greenwood cuttings under glass.

*arbutifolia*, Spach (*Sorbus arbutifolia*. Heynh. *Pyrus arbutifolia*, Linn. f. *A. arbutifolia*, Ell. *A. pyrifolia*, Pers. *Mespilus arbutifolia* var. *erythrocarpa*, Michx.). RED CHOKEBERRY. Upright shrub, 6-10 ft. high: lvs. short-petioled, oval to oblong or obovate, acute or abruptly acuminate, crenately serrate, glabrous above except some glands on the midrib, whitish or grayish green and tomentose or pubescent beneath,  $1\frac{1}{2}$ -3 in. long; corymbs tomentose, few- to many-fld.,  $1-1\frac{1}{2}$  in. broad; fls. white or tinged red,  $\frac{1}{2}$ - $\frac{1}{2}$  in. across: fr. subglobose or pear-shaped, bright or dull red, about  $\frac{1}{4}$  in. across. April. May. N. Y. to Minn., to Fla. and La. B.M. 3668. G.F. 3:417. G.W. 5, p. 245.

*atropurpurea*, Brit. (*Sorbus arbutifolia* var. *atropurpurea*, Schneid.). PURPLE CHOKEBERRY. Shrub, to 12 ft., closely allied to the last: lvs. oblong to obovate, grayish pubescent beneath,  $2-3\frac{1}{2}$  in. long; corymbs tomentose, many-fld.: fr. ovoid to subglobose, purplish black, about  $\frac{1}{2}$  in. high. May, June. Nova Scotia to Fla.

*melanocarpa*, Spach (*Sorbus melanocarpa*, Heynh. *Pyrus nigra*, Sarg. *A. nigra*, Koehne. *Pyrus arbutifolia* var. *nigra*, Willd.). BLACK CHOKEBERRY. Low shrub, rarely to 6 ft.: lvs. oval to obovate, abruptly acuminate or obtuse, pale green and glabrous or nearly so beneath: calyx and pedicels glabrous or nearly so: fr. globose, about  $\frac{1}{2}$  in. across, shining black. Nova Scotia to Ont., south to Fla. and Mich. April-June. B.B. 2:237. Var. *grandifolia*, Schneid. (*Pyrus grandifolia*,

382. *Aronia melanocarpa* var. *elata*. ( $\times \frac{1}{2}$ )

Lindl.). A taller, more vigorous shrub with larger, obovate or broadly obovate lustrous lvs. and larger fls. in larger corymbs. B.R. 14:1154. Var. *elata*, Rehd. Fig. 382. Similar to the preceding, but lvs. narrower, generally oblong-obovate, acute. Var. *subpubescens*, Schneid. Lvs. pubescent beneath when young.

*A. floribunda*, Spach (*Pyrus floribunda*, Lindl.). Hybrid between *A. arbutifolia* and *A. melanocarpa*, similar to *A. atropurpurea*, but usually more glabrescent. B.R. 12:1006. G.W. 5, p. 246.—It is of garden origin and several forms of it are in cult.

**ARONICUM:** *Doronicum*.

ALFRED REHDER.

**ARPOPHYLLUM** (*cimiter* and *leaf*). *Orchidaceæ*. Epiphytic evergreen orchids, with 1-lvd. sts. arising from creeping rhizomes: lvs. coriaceous or fleshy: fls. numerous, sessile, in dense cylindric spikes; sepals and petals nearly alike, spreading; lip adnate to base of the erect column, narrowed above the somewhat saccate base; pollinia 8.—About 6 species, natives of Mex., Cent. Amer., and W. Indies.

**gigantæum**, Lindl. Sts. stout, up to 1 ft. tall: lvs. 12–16 in. long: spike dense, up to 1 ft. long; fls. rose-purple, the broadly obovate lip deeper. Mex. and Guatemala.

**spicatum**, Llav. & Lex. Fig. 383. Sts. up to 8 in. tall: lvs. up to 1 ft. long: spike dense, 3–6 in. long; fls. less than  $\frac{1}{2}$  in. across, numerous; sepals and petals rose-purple; lip bright purple. Mex. B.M. 6022.

GEORGE V. NASH.

**ARRACACIA** (Spanish name of the plants). *Umbelliferae*. Also spelled *Arracacha*. Twenty to 30 species of perennial herbs closely allied to *Conium*, with calyx-teeth very small or wanting, petals broad, acuminate and inflexed, white to dark purple, fls. in large compound umbels: lvs. pinnately compound or decomposed. *A. xanthorrhiza*, Bancr. (*A. esculenta*, DC.), produces edible tuberous roots much eaten by residents of N. S. Amer.; these tubers have branches or lobes the size of carrots, and are boiled. *A. Dugesii*, Coulter & Rose, Cent. Amer., is reported as a botanic-garden plant. It is tall and coarse, aromatic: lvs. much decomposed, segm. linear.

**ARRHENATHERUM** (Greek *arren*, masculine, and *ather*, awn, in reference to the awned staminate flower). *Gramineæ*. OAT GRASS. Tall perennials with flat blades and long narrow panicles: spikelets 2-fl'd., the lower staminate, its lemma bearing a geniculate twisted dorsal awn, the upper perfect, short-awned or awnless. Species 6, Medit. region. One species, tall oat-grass (*A. elatius*, Beauv.), is cult. as a meadow grass. Dept. Agric., Div. Agrost. 20:95. There has been recently intro. into the eastern states a variety (var. *tuberosum*, Halac. *A. bulbosum*, Presl) that bears at the base of the culms a short chain of corms. A variegated form of this has been offered under the name *A. bulbosum variegatum*. A. S. HITCHCOCK.

**ARROW-ROOT**. An edible starch, derived from the rhizomes of various scitamineaceous plants, as *Maranta*, *Curcuma*, *Tacca*, *Canna*. The West Indian arrow-root is mostly from *Maranta arundinacea*. The Brazilian is from *Manihot utilissima*. The East Indian is chiefly from *Curcuma angustifolia*. Potato and maize starches are also a source of arrow-root. In the United States starch is secured from Cassava (*Manihot utilissima*) and is used as a substitute for arrow-root. See *Cyclo. Amer. Agric.*, Vol. II, p. 199, with figure of *Maranta arundinacea*.

**ARTABOTRYS** (Greek, *suspended grapes*, alluding to the clustered fruit suspended by the hooked peduncle). *Annonaceæ*. CLIMBING YLANG-YLANG. TAIL-GRAPE. Woody tropical climbers or scrambling shrubs, remarkable for their curiously hooked peduncles, and prized for the fragrance of their flowers.

Leaves smooth, evergreen, alternate: petals 6 in 2 series, both series valvate or edge-to-edge, in most species flat but in certain Malayan and African species terete or club-shaped, with a broad excavated base, above which they are constricted and connivent over the essential parts, which they almost conceal, the flat or terete limb above the constriction usually spreading and ascending, sometimes slightly incurved: stamens typically annoneaceous, closely packed, wedge-shaped or oblong with 2 dorsal pollen-sacs on the back of the thick filament and connective produced above them in the

form of a dilated hood or cap: ovaries several, seldom numerous, each with 2 erect basal ovules side by side; styles variable, sometimes oblong or club-shaped and reflexed, sometimes erect or very small; ripe carpels separate, borne in a cluster on the hardened torus or receptacle, either sessile or stipitate, more or less plum-like or olive-like, and normally containing 2 flattened seeds with hard bony testa, rising side by side from the base, grooved around the margin and containing the wrinkled albumen characteristic of all *Annonaceæ*. E. Asia, the Malay Archipelago, and Trop. Afr.—About 40 species thus far described, several of them cult. in tropical countries and grown in conservatories for their fragrant fls.

Several of the most common species have been confused. *Artabotrys uncinatus* was described by Lamarck under the name *Annona uncinata* in 1786. It was supposed to be identical with *Artabotrys odoratissimus*, R. Br., the type species of the genus, which was established in 1819. Its flowers, however, are described as having ovate-lanceolate petals with a brownish red upper part

383. *Artabotrys spicatum*. ( $\times \frac{1}{6}$ )

(or limb), and with broad claws at the base, cottony, concave within at the base and constricted between the claw and the blade. It is consequently to be identified with *Artabotrys odoratissimus* of Blume, which is distinct from *A. odoratissimus*, R. Br., and which was described as *A. Blumei* by Hooker & Thomson; while *A. odoratissimus* of Hooker & Thomson is to be referred to *A. hamatus* of Blume; and *A. intermedius*, Hassk., is regarded as a variety of *A. odoratissimus*, R. Br.

A. Shape of petals lanceolate or ovate, flat.

B. Petals glabrous, more than an inch long.

**odoratissimus**, R. Br. CLIMBING YLANG-YLANG. ALANG-ILANG SONGSONG. TAIL-GRAPE. ALANG-ILANG DE CHINA. A woody climber or half-scandent shrub: young branches puberulous, at length glabrous: lvs. short-petioled, oblong or oblong-lanceolate, acuminate, acute at the base, thin, coriaceous, both sides glabrous, glossy, reticulate between the lateral nerves: hooked peduncles 1- or 2-fl'd., extra-axillary, usually opposite a lf. or subterminal; fls. rather large, greenish to yellow, very fragrant; petals flat, glabrous, or silky-puberulous at the base, thick and coriaceous, lanceolate to oblong-lanceolate, nearly 2 in. long when full-grown, constricted near the base and connivent over the essential parts, widely spreading above the constriction, inner petals similar to the outer but slightly smaller; stamens numerous, short and thick, wedge-shaped, with the connective broadly dilated above the 2 pollen-sacs, which are adnate on the back of the fleshy filament and open extrorsely by longitudinal fissures; ovaries

glabrous, several, each with 2 erect ovules at the base; styles linear-oblong or club-shaped: berries plum-like, clustered on the hardened receptacle, oblong, narrowed at the base, nearly sessile, with a small point at the apex, smooth, yellow and fragrant when ripe. S. China, Formosa, India, Ceylon, Burma, Philippine Isls. B.R. 423.—A species widely cult. in the warm countries of the eastern hemisphere and in conservatories, for its fragrant fls. and frs. This species is tender in Cent. Fla. and should be banked with dry sand. It needs rich soil and should be well fertilized each year. Easily prop. by seeds.

BB. *Petals tomentose or pubescent, not exceeding an inch in length.*

C. *Fr. ovoid, sharp-pointed: petals ovate-lanceolate, brownish red, pubescent.*

**uncinatus**, Safford (*Annona uncinata*, Lam.). Fig. 384. A shrub with climbing divaricate branches; young branches slightly pubescent at first, at length glabrous, more or less zigzag; lvs. lanceolate or oblong-lanceolate, acuminate, usually acute at the base, glabrous on both

384. *Artabotrys uncinatus*.  
( $\times \frac{1}{2}$ )

sides, glossy, and with short thick petioles, 5–10 in. long by 2–3 in. broad: hooked peduncles glabrous, curved downwards almost like a spiral, somewhat flattened, usually opposite a lf., often with the portion of the branch above it more or less aborted, so as to make it appear terminal; calyx 3-parted, the divisions ovate-acute; petals 6, ovate-lanceolate, brownish red on the upper part, with broad claws, woolly or pubescent (“cottonneux”), concave within and constricted between the claw and the limb, the 3 outer petals about  $\frac{3}{4}$  in. long, somewhat larger than the inner, and relatively broader; ovaries about 8–12, gradually tapering upward to the obtuse stigmatic apex, clothed with minute hairs, and containing 2 basal collateral erect ovules: frs. several, rounded-ovoid, abruptly pointed at the apex, nearly sessile, about the size of a walnut inclosed in its hull, at length smooth, lightly punctate, and inclosing 2 oblong seeds truncated at the base, rising side by side from the base, more or less compressed and bearing a marginal groove around the periphery of the hard bony testa.—This species was described by Lamarck from specimens collected by Sonnerat in the E. Indies and Madagascar (see figs. Dunal Anon. pls. 12. 12a). It is very closely related to

*A. odoratissimus*, R. Br., from which it apparently differs in the broader shape, reddish brown color, and “cottony” indumentum of its petals. If, as supposed by many botanists, the two species are identical, the specific name *uncinatus* of Blume, which it more closely resembles, the latter, set apart by Hooker & Thomson as a distinct species under the name *A. Blumei*, must yield to the earlier specific name, and *A. odoratissimus*, R. Br., be retained as a species distinct from Lamarck’s though supposed by its author and his followers to be identical with it. *A. uncinatus*, like its very close ally, *A. odoratissimus*, is frequently planted in the warm regions of the eastern hemisphere for the sake of its fragrant fls.

CC. *Fr. tapering at both ends: petals linear-lanceolate, tomentose.*

**hamatus**, Blume (*A. odoratissimus*, Hook. f. & Thomson). A large scrambling shrub with elongate sarmentose glabrous branches; lvs. oblong-lanceolate, obtusely acuminate, acute at the base, 2–4 in. long by 1–1½ in. broad, coriaceous, glabrous, delicately veined on both surfaces: hooked peduncles flattened, glabrous, spirally curved, several-fl’d. but usually all but one of the fls. abortive; pedicel curved, clothed with short pubescence and bearing at the base a sessile ovate caducous bracteole; fls. yellowish ferrugineous; calyx minute, subtomentose, deciduous, deeply 3-parted, the divisions broadly ovate-acute, spreading and reflexed; outer and inner petals of equal length, 1 in. long, linear-lanceolate, obtusely acuminate, thickish, tomentose, excavated and constricted at the base, conniving over the essential parts and almost concealing them, the limb, above the constriction, curving somewhat inward, with a raised median line along the back and a groove within, the outer petals somewhat broader than the inner; receptacle plano-convex, clothed with minute hairs; stamens numerous, thick, club-shaped, obtuse, the connective swollen and rounded above the pollen-sacs; ovaries few, about 5–8, linear-oblong, glabrous, tapering upward into the terete style; mature hardened receptacle bearing 3–5 fruiting carpels 2–2½ in. long and 1 in. diam., tapering toward both ends, obtusely acuminate, rather smooth, marked with longitudinal lines within from the base to the apex and spotted with greenish and white, at length turning red; seeds 2, erect, side by side, oval, with a hard bony pericarp surrounded by a marginal groove, and a large ruminant albumen. Java, common at the base of high mts.—Widely diffused in India and Ceylon, and planted for the sake of its fragrant fls., often scrambling over garden walls. Closely allied to this species is *Artabotrys intermedius*, Hassk., which grows in the botanical gardens of Buitenzorg, on the island of Java. Its calyx is described as silky within, its petals as green and covered with fine tomentum, the exterior ones a little broader and longer than the inner (an inch long), and ovate-lanceolate in shape, and the ripe carpels obovoid and acutish.

AA. *Shape of petals cylindrical or club-shaped, fleshy: peduncles several-fl’d.*

**suaveolens**, Blume. BUFFALO THORN. DURIE CARABAO. SUSONG DAMULAG. A large woody climber or scrambling shrub: young branches puberulous: lvs. elliptic-oblong to oblong-lanceolate, 2–5 in. long by 1–1½ in. broad, acuminate, at the acute or obtuse base usually narrowed into a short glabrous petiole, coriaceous or subcoriaceous, glabrous or pubescent on the midrib beneath, glossy above, conspicuously veined on both sides: peduncles short, recurved or hooked, flattened and fasciated, puberulous, several-fl’d.; fls. very fragrant, small, yellow, borne on pedicels  $\frac{1}{2}$  in. long or less; petals all similar, about  $\frac{1}{2}$  in. long, fleshy, terete or club-shaped, broad and concave at the base, where they connive to form a dome-shaped covering over the essential parts; stamens many, short and thick,

wedge-shaped, with a very broad truncate or flattened connective above the two pollen-sacs; ovaries few, about 3-5, broadly ovoid, subcompressed, terminating in a small stigma and containing 2 basal ovules; fruiting carpels 2 or 3, oblong, obtuse, slightly contracted at the base, sessile; seed usually solitary. All Malayan provinces at low elevations, common; distribution from Sylhet to Burma; also occurring in the Philippines.—The natives use this plant to form hedges and fences, interweaving the long sarmentose branches, which form an effective barrier against cattle and buffalo. Often planted near houses on account of the exquisite fragrance of its fls. Suitable for forming inclosures in Fla., Porto Rico, Hawaii, and S. Calif.

W. E. SAFFORD.

**ARTEMISIA** (*Artemisia*, wife of Mausolus). *Compositæ*. WORMWOOD. A large genus of aromatic and bitter herbs and small shrubs, mostly in the northern hemisphere, and most abundant in arid regions.

Leaves alternate, often dissected: heads small and mostly inconspicuous, numerous, and generally nodding, with yellow or whitish florets, wholly discoid, the involucre imbricated in several rows.

In the West, many of the species, particularly *A. tridentata*, are

known as sage brush. Grown for their medicinal properties or for foliage effects. The drug product of the artemisias is large. *A. Absinthium* is the chief source of absinthe; *A. Barrelieri*, Bess., of Spain, is said to be used in the preparation of Algerian absinthe; *A. Cina*, Berger, of the Orient, is the source of santonica. The garden kinds are perennials and thrive in the most ordinary conditions, even in poor and dry soil. Propagation is mostly by division.

A. Heads with two kinds of florets (heterogamous).

B. Disk-fls. with both stamens and pistils, but the ovary abortive (not producing seed); style usually entire.

1. **Dracunculus**, Linn. TARRAGON. ESTRAGON. Herb; green and glabrous, with erect, branched sts. 2 ft. high: radical lvs. 3-parted at the top; st.-lvs. linear or lanceolate, entire or small-toothed: panicle spreading, with whitish green, nearly globular fl.-heads. Eu. R. H. 1896, p. 285.—Tarragon lvs. are used for seasoning, but the plant is little grown in this country. The lvs. may be dried in the fall, or roots may be forced in a coolhouse in the winter. Prop. by division; rarely produces seed. See *Tarragon*.

2. **canadensis**, Michx. Herb, 2 ft. or less high, glabrous or very nearly so: lvs. usually 2-pinnate, with filiform, plane lobes: fls. in a long, narrow panicle, with numerous small greenish heads. Wild on banks and plains in the northern part of the country.

3. **filifolia**, Torr. Shrubby, canescent, 3 ft. or less high, very leafy, the branches rigid: lvs. 3-parted into linear filiform segms., scarcely  $\frac{1}{8}$  in. wide: panicle long and leafy. Plains, W.—Plant has a purplish, mist-like aspect when in fr.

BB. Disk-fls. perfect and fertile; style 2-cleft.

c. Receptacle hairy.

D. Racemes not 1-sided.

4. **frigida**, Willd. Herb, 8-12 in., with a woody base, silvery canescent: lvs. much cut into linear lobes: heads small and globular, with pale involucre, in numerous racemes. Plains and mts. W. Intro. 1883.—Good for borders. Known in Colo. as "mountain fringe," and used medicinally.

5. **sericea**, Web. Sub-shrub or more usually a creeping woody perennial with finely divided silky foliage: lf.-segms. distinctly stalked: fl.-heads in solitary or paniculately branching racemes, yellowish white. Summer. Siberia.

6. **argentea**, L'Her. Shrubby, erect, 1-2 ft.: lvs. white-silky, 2-pinnate, the lobes linear or lanceolate: heads globular, tomentose, nodding, in racemose panicles. Madeira.—Useful for rockwork.

7. **Absinthium**, Linn. WORMWOOD. ABSINTHIUM. Almost shrubby, 2-4 ft. high, spreading and branchy, white-silky: lvs. 2-3-parted into oblong, obtuse lobes: heads small and numerous, in leafy panicles.—Wormwood is native to Eu., but it occasionally escapes from gardens. It is a common garden herb, being used in domestic medicine, especially as a vermifuge. Wormwood tea is an odorous memory with every person who was reared in the country. See *Absinthe* and *Wormwood*.

DD. Racemes 1-sided.

8. **arborescens**, Linn. Shrubby, 1-2 ft., the sts. erect and angled: foliage finely dissected, silvery white, the upper lvs. almost sessile, the lower petiolate: fls. in somewhat 1-sided racemes, bright yellow. Medit. region.—Hardy only as far north as Washington, D. C.

cc. Receptacle not hairy.

D. Lvs. white or silvery throughout.

9. **Stelleriana**, Bess. (*A. endoviciana*, Hort.). OLD WOMAN. DUSTY MILLER. BEACH WORMWOOD. Fig. 385. Herb, 2 ft., from a woody creeping base, densely white tomentose: lvs. pinnatifid, with obtuse lobes: heads large and many-fld., in a racemose-glomerate infl. N. E. Asia and on the Atlantic coast from Mass. to Del.—Attractive from its whiteness. Useful for borders.

10. **Purshiana**, Bess. (*A. gnaphalodes*, Nutt. not Hort.). Sts. and lvs. white-woolly on both sides, differing from *A. ludoviciana* in which the lvs. are usually glabrate above when old: lvs. acute or acuminate, overtopped by the spicate-paniculate infl. of white fls. Missouri R. to the Pacific.

386. *Artemisia pontica*.  
( $\times \frac{1}{2}$ )

385. *Artemisia Stelleriana*, one of the  
Dusty Millers.

DD. *Lvs. white on 1 side only or green throughout.*

11. *Abrótanum*, Linn. SOUTHERNWOOD. OLD MAN. Shrubby, 3-5 ft., green and glabrous, the st. much branched and rather strict: lvs. 1-3-pinnately divided, the divisions fine-filiform: panicle loose, with yellowish white heads. Eu.—Southernwood is grown for its pleasant-scented foliage; and it sometimes escapes into waste places. See *Southernwood*.

387. *Artemisia vulgaris*.  
( $\times \frac{1}{2}$ )

ful plant with fragrant foliage. G. 29:409.—Mugwort is grown for the ornament of its foliage. There are variegated-lyd. and golden-lyd. varieties. It was once a domestic remedy. Variable.

14. *ludoviciana*, Nutt. WESTERN MUGWORT. WHITE SAGE. Erect or ascending herb, 2-3 ft., white-tomentose or lvs. becoming greenish above: lvs. linear to oblong, the lower ones toothed or parted, the upper ones entire: heads small, bell-shaped, paniculate. Plains and banks, W. Intro. 1891.

AA. *Heads with perfect fls. throughout: receptacle not hairy.*

15. *arbúscula*, Nutt. SAGE BRUSH. Shrubby, a foot or less high: lvs. short, wedge-shaped, 3-lobed, the lobes obovate and often 2-lobed, canescent: panicle simple and strict, often spike-like, the 5-9-fl. heads erect. Plains and mts., Colo. and Wyo., N. W.

16. *tridentata*, Nutt. SAGE BRUSH. Shrubby, reaching height of 12 ft. although often only a foot high, branchy, canescent: lvs. wedge-shaped, 3-7-toothed or lobed, truncate at the summit, the uppermost ones narrower: heads 5-8-fl. Plains, W. Intro. 1881.

388. *Artemisia lactiflora*. No. 13.

12. *pónica*, Linn. ROMAN WORMWOOD. Fig. 386. Shrubby, erect, 1-4 ft.: lvs. canescent below, pinnatisect, the lobes linear: panicle open and long, with small, globular, nodding, whitish yellow heads. Eu.—Roman wormwood is used for the same purposes as *A. Absinthium*, and is more agreeable. A source of absinthe.

13. *vulgáris*, Linn. MUGWORT. Fig. 387. Herb, erect, paniculately branched, the sts. often purplish: lvs. white-cotony beneath but soon green above, 2-pinnately cleft, with lanceolate lobes; upper lvs. sometimes linear: heads many, oblong, yellowish. Eu. and N. Amer., and naturalized in eastern states.—A white-fl. form has been sold as *A. lactiflora*. Fig. 388. It is a beautiful

17. *sacròrum*, Ledeb. Annual or biennial, shrubby below: lvs. long-petioled, ovate, pinnatisect and the segms. again pectinate, hoary or white-pubescent, the rachis winged: fls. 15-20 in the head, the heads nodding and in separate slender racemes. S. Russia, Siberia, etc. Var. *viride*, Hort., with green foliage, is the attractive SUMMER FIR recently intro., grown as an annual for its neat pyramidal form (3-5 ft.) and much dissected rich green foliage.

*A. Baumgarteni*, Bess. Compact, shrub-like, with small lvs. and yellow fls. standing erect above the lvs. S. Eu.—*A. lanáta*, Willd (*A. pedemontana*, Balbis). Low caespitose plant with finely cut, silvery foliage for which it is chiefly grown. Spain.

N. TAYLOR.†

389. Globe artichoke.

ARTHROPÒDIUM (Greek, *joint* and *foot*, alluding to jointed pedicels). *Liliaceæ*. Herbaceous perennials, allied to *Anthericum*, grown in the open in the South and otherwise in greenhouses.

Tufted herbs 1-3 ft. high, with fibrous fleshy roots: lvs. linear or lanceolate, crowded at base of st.: scape simple or branched; fls. white or violet, in racemes or panicles, on pedicels jointed at the middle; perianth persistent, the segms. 6 and distinct and 3-nerved; stamens 6, shorter than perianth: fr. a subglobose caps., 3-valved.—About 10 species in Austral., New Zeal., etc. Cult. and prop. as for *Anthericum*, requiring no special treatment.

*cirrhatum*, R. Br. Glabrous, to 3 ft.: lvs. numerous, deep green, 2 ft. or less long: scape stout, naked, bearing a much-branched panicle often 1 ft. long; fls. white, star-shaped, 1 in. or less in diam., the segms. oblong-lanceolate, acuminate; filaments bearing 2 tendril-like appendages (whence the name). New Zeal. B.M. 2350.—Reported in S. Calif. L. H. B.

ARTHROTÁXIS: *Athrotaxis*.

ARTICHOKE (*Cynara Scolymus*, Linn.). *Compositæ*. The artichoke (or the Globe artichoke, to distinguish it from the Jerusalem artichoke) is a strong thistle-like plant (Fig. 389), grown for the edible flower-heads (Fig. 390). It is native in southern Europe and northern Africa, and is not hardy in the northernmost parts of the United States. It is perennial, but the plantation should be renewed every two or three years. See *Cynara*.

The artichoke is propagated by seed or by suckers. The latter is the preferable method, for a good strain or variety may thus be perpetuated. The buds or shoots are detached from the old crown in spring before growth begins. Seeds produce bearing plants the following year, although heads may be secured the same autumn if the season is long and if the seeds are started early under glass.

The soft fleshy receptacle of the flower-head and the thickened base of the scales (or involucre bracts)

are the edible parts. They are sometimes eaten raw, but are usually boiled and served with drawn butter or sauce. The leaves are sometimes blanched after the manner of sea-kale and cardoon, and are cooked as a pot-herb.

In the southern states and California, the artichoke is grown without difficulty. In California, particularly, it thrives as a field crop. In northern gardens, even professional and skilled gardeners have usually given

390. Edible heads of artichoke. ( $\times \frac{1}{2}$ )

Instead of covering with manure or litter, place a cap or miniature tent over the crown to give it air and freedom of breathing. The flower-heads are now regularly and commonly found on sale at the green grocers' in our larger eastern cities, and the supply comes mostly from California. The large seeds may need special treatment to make them germinate promptly. The better way, undoubtedly, for the home gardener who may wish to try a few plants, is to secure sucker plants from one of the big seedsmen or professional plant-growers. Set them in fairly good warm soil, 3 feet each way, or 4 by 2, and give clean cultivation. Protect the crowns during winter as suggested, and in following spring thin to about three shoots. Edible heads may be expected in July. They are gathered for use before the flower-heads open. It is better to cut the old stalk down to the ground after the head is removed, for the root is not then weakened and new shoots will spring up. There are a number of varieties, Large Green Paris being the one mostly mentioned in California. In parts of Europe the artichoke is grown with special skill, but it has never been a prominent vegetable in American gardens.

T. GREINER.

**ARTICHOKE, JERUSALEM** (*Helianthus tuberosus*, Linn.). *Compositæ*. The Jerusalem artichoke is the subterranean stem tuber of a native sunflower. Fig. 391. The plant is coarse and upright, and persists as a weed when once introduced. It does not need excessively rich soil, nor high culture, succeeding on any warm well-drained land without attention. It is planted much after the manner of potatoes, and it will grow and produce its many smallish, white, edible tubers.

391. Tuber of Jerusalem artichoke. ( $\times \frac{1}{2}$ )

In late fall, the plants may be pulled up, exposing to view the tubers that are clustered around the roots near the main stalks so that they can be easily gathered with the help of a hoe or potato hook, if wanted for use as a culinary vegetable; or, if grown for hog-feed, the hogs may be turned right into the field and allowed to dig their own. All farm stock seems to like the artichoke tubers. If shredded or ground and mixed with meals, they make a good winter ration, as a variety, for poultry. More prolific than common potatoes, and far more

easily grown, the artichoke is one of the crops that may be considered for cultivation as a succulent vegetable to feed to cattle, swine, and other farm animals during winter. Raw or boiled and served cold with oil and vinegar, this tuber also makes a very palatable winter or spring salad, and for this purpose it finds a limited sale in our markets. The chief commercial demand for it is for seed purposes. Frost has no injurious effect on the tuber in the ground, and the easiest way to winter it, therefore, is by leaving the plants alone until spring and then digging the tubers. If already harvested, they may be pitted like potatoes, beets, or other roots, and will require very little covering. Mammoth White French is said by some propagators to be an improved strain of the Jerusalem artichoke. If there is danger of the plant spreading and becoming a weed, hogs, when given a chance at it, will soon clear the land of the tubers. It was cultivated by the Indians. See *Helianthus*.

T. GREINER.

**ARTOCÁRPUS** (*artos*, bread, and *carpos*, fruit). *Morææ*. BREAD-FRUIT. Milky-juiced tropical trees, some of them yielding edible fruits, ornamental in foliage.

Leaves alternate, large, thick, entire or pinnate; dioecious; staminate fls. on long spikes, the sepals and

392. Bread-Fruit.—*Artocarpus incisa*, showing a fruit of edible size. ( $\times \frac{1}{2}$ )

stamens 2; pistillate fls. in globular heads, with simple 1-ovuled ovary and bifid stigma; fr. a large fleshy mass or syncarp, formed of the aggregated fls.—A genus of 40 species containing many tropical fr. plants, originally from the E. Indies, sometimes cult. with difficulty in northern botanic gardens for their great economic interest, and throughout the world in the tropics. They need a hot, moist atmosphere, much water, and perfect drainage. Prop. slowly by cuttings of young lateral growth. Bread-fruit seeds are boiled and eaten.

*incisa*, Linn. f. (*A. communis*, Forst.?). BREAD-FRUIT. Fig. 392. Tree, 30-40 ft., with a viscid, milky juice; branches fragile; lvs. 1-3 ft. long, leathery, ovate, cuneate and entire at base, upper part 3-9-lobed; male fls. in a dense club-shaped yellow catkin, 10-16 in. long; female fls. in a subglobular echinate head, having a spongy receptacle; fr. 4-6 in. diam., typically mucated, but in the best cult. varieties reticulated only, and often seedless. Gt. 39, p. 273. Gng. 5:233, and

B.M. 2869-2871, where the romantic story of its transfer to the W. Indies is told.—Sparingly cult. in S. Fla. and in greenhouses of botanic gardens. Eaten cooked, as a vegetable rather than as a fruit; widely used in tropics.

393. Jack-Fruit.—*Artocarpus integrifolia*.

**integrifolia**, Linn. f. JACK-FRUIT OR TREE. Called also JACA. Fig. 393. Tree, 30 ft., with milky juice: lvs. 4-6 in. long, very various; those of fertile branches nearly obovate, entire; those of young shoots from the root very narrow, or 2-3-lobed: fr. attaining a length of 18 in. or more, and weight of 30-40 lbs. G.C. III. 20:717. B.M. 2833, 2834. Gt. 39, p. 273. Gn. 35, p. 455.—Less palatable than the bread-fruit, and usually eaten only by natives and coolies.

**Cannonii**, Bull. Lvs. varying from cordate to deeply 3-lobed, 1 ft. long, red beneath, bronzy crimson and purple above, very showy. Society Isls. F.S. 21:2231, 2232.—Perhaps better included under *Ficus Cannonii*, according to Nicholson, but here retained in *Artocarpus*.

N. TAYLOR.†

**ARUM** (ancient name). *Araceæ*. WILD GINGER. Tuber-bearing low herbs, of few species, in Eu. and W. Asia, most of them grown in pots.

Lvs. simple, the petiole sheathed at the base: spathe convolute, variously colored, mostly including the short spadix; pistillate fls. at the base. Monogr. by Engler in DeCandolle's *Monographia Phanerogamarum*, Vol. II.

Arums are grown usually as oddities, mostly under the general name of callas. Some of the species are hardy; others, as *A. palæstinum*, are tender, and require glass-house treatment. The kinds are managed in essentially the same way as the fancy-leaved caladiums. Plant the tubers sufficiently deep that roots may form from near the top. Give rich soil, and water freely when growing or in bloom. The hardy species should be well mulched in late fall. They thrive best in partially shaded places and in rich soil. Propagation is by natural offsets; also by seeds or berries, which some species produce freely. Some of the species are acrid-poisonous.

A. Mature lvs. cordate, oblong-ovate.

1. **pictum**, Linn. f. (*A. corsicum*, Loisel). Lvs. appearing in spring, long-petioled, light green: spathe bright violet, swollen at the base: spadix purple-black, exceeding the spathe. Corsica, Balearica, etc.—Hardy.

AA. Mature lvs. hastate or sagittate.

B. Tuber round-flattened or oblate, the lvs. and peduncles arising from a depressed center: lvs. appearing before the spathe.

2. **Dioscoridis**, Sibth. & Smith (*A. spectabile*, Regel. *A. syriacum*, Blume. *A. cyprium*, Schott). Lf.-blade oblong-triangular or ovate-triangular: spathe-tube pale within, the limb 6-8 in. long, lanceolate-oblong, and colored with large lenticular purple spots: spadix short, included. Asia Minor.—Runs into many forms, with variously marked spathes. Pots.

3. **detruncatum**, Mey. Lvs. more or less truncate at the base, the blade shorter than in the last: spathe yellowish green and purple-spotted, large (10-15 in. long) and short-stalked, the limb acuminate. Persia.—Hardy.

4. **palæstinum**, Boiss. (*A. sanctum*, Hort.). BLACK CALLA. SOLOMON'S LILK. Lvs. cordate-hastate, 6 in. broad across the base and about equal in length, the middle lobe broad-ovate and nearly blunt: spathe about the length of the lf., with a short green tube, and an elongated lance-oblong tapering limb, which is greenish on the outside and continuous black-purple within, the tip sometimes recurving: spadix shorter than the spathe, the upper part dark-colored. Palestine. B.M.

394. *Arum maculatum*. (×¼)

5509. Gn. 45, p. 311; 59, p. 317; 71, p. 102.—Perhaps the most popular arum at present, being grown in pots as an oddity.

5. **orientale**, Bieb. A foot high: lvs. brownish, broadly hastate-sagittate, the front lobe oblong-acute: spathe-tube oblong-ovoid and white within, the limb ovate to oblong and intense black-purple (rarely pale), resembling *A. maculatum*.—A hardy species from Asia Minor, running into many forms. Some of the plants

referred here are *A. nigrum*, *A. variolatum*, *A. Nordmannii*, *A. gratum*, Schott; *A. elongatum* and *A. albispathum*, Ster. (not *A. albispathum*, Hort., which is *A. italicum*).

**BB.** *Tuber ovoid or oblong, propagating horizontally, the lvs. and peduncles arising from the apex: lvs. appearing before or with the spathe.*

**6. maculatum**, Linn. (*A. vulgare*, Lam.). LORDS-AND-LADIES. CUCKOO-PINT. WAKE

ROBIN (in England). Fig. 394. About a foot high: lvs. usually black-spotted, hastate or sagittate, the front lobe triangular-ovate, about as high as the spathe: spathe somewhat contracted above the base, the margins of the limb becoming inrolled, spotted with purple: spadix shorter than the spathe, purple. Eu.—A hardy species, of many forms. A form with spotted lvs. and whitish tube with medial purple zone, is *A. immaculatum*, Reichb., and *Zelebör*, Schott. Var. *angustatum*, Engler (*A. intermedium*, Schur. *A. Malyi*, Schott) has a narrow light purple spathe. Var. *alpinum*, Engler (*A. alpinum*, Schott & Kotschy) has peduncles longer, and an ovate-lanceolate spathe.

**7. italicum**, Mill. (*A. cylin-draceum*, Gasp.). Fig. 395. Larger than the last: lvs. hastate, nearly truncate below, light-veined: spathe scarcely swollen below, the limb erect and not expanding and including the short spadix (tip sometimes deflexed after flowering), yellowish or white and faintly striate. Eu. B.M. 2432.—A hardy species; also grown in pots. In the open, the lvs. appear in the fall. A very variable species. Var. *canariense*, Engler (*A. canariense*, Webb & Berth.), has narrow lf.-lobes and spathe. Var. *concinatum*, Engler (*A. concinatum* and *A. marmoratum*, Schott), has broad gray-spotted lvs. Var. *byzantinum*, Engler, (*A. byzantinum*, Schott), has spathe-tube oblong, white inside and purple at the mouth, and an acuminate purple or green limb. Var. *albispathum*, Hort., has a white spathe.

L. H. B.

**ARÚNCUS** (old name). *Rosaceæ*. GOAT'S-BEARD. Ornamental tall perennial herbs, cultivated chiefly for the large showy panicles of white flowers and also for the handsome much-divided foliage.

Leaves bi- to tripinnate with minute or wanting stipules: fls. dioecious, small; calyx 5-lobed; petals 5; stamens many; pistils commonly 3: the follicles dehiscent, glabrous, usually 2-seeded; seeds minute, dull.—Two species in N. Amer., N. and W. Eu., N. Asia to Japan. Formerly usually referred to *Spiræa*, which differs chiefly in its shrubby habit, simple, rather small lvs., and 5 pistils.

They are tall perennial herbs with large compound leaves and small white flowers in slender spikes forming large terminal panicles. The species in cultivation is hardy North; it prefers rich rather moist soil and grows well in half-shady situations. Propagation is by seeds, which germinate readily, and also by division of older plants.

**sylvester**, Kostel. (*A. Aruncus*, Karsten. *Spiræa Aruncus*, Linn.). Tall (5–7 ft.), erect branchy herb: lvs. large, 2–3-pinnate; fls. ovate to lanceolate, sharply and doubly serrate, 1–2½ in. long: fls. about ½ in. across: follicles deflexed in fr. May–July. Rich woods, N.

Amer., N. Eu. and Asia.—A desirable hardy border plant of easy cult. Var. *Kneiffii*, Zabel. Lfts. linear-lanceolate, irregularly serrate or incised, long-acuminate: fls. as in the type. M.D.G. 1897:260.—Very graceful form with its finely cut foliage.

*A. astilboides*, Maxim. (*Spiræa Aruncus* var. *astilboides*, Maxim.). Similar to the preceding, but lower and smaller in every part: lfts. more deeply serrate, ¾–1½ in. long: infl. less compound, with denser oblong branchlets: follicles erect. Japan.—Apparently not in cult.; the plant cult. under the name of *Spiræa astilboides* is *Astilbe astilboides*, Lem., which is a true *astilbe*.

ALFRED REHDER.

**ARUNDINÀRIA: Bamboo.**

**ARÚNDO** (an ancient Latin name for *A. Donax*). *Gramineæ*. REED. Tall reed-like grasses with broad

flat blades and large plume-like terminal panicles: spikelets 3–4-fld.; glumes narrow, acute; rachilla naked; lemmas long-pilose.—Species about 6, in the warmer regions of the Old World.

**Dónax**, Linn. GIANT REED.

Figs. 396, 397. Tall and stout,

as much as 20 ft., from large knotty rootstocks: blades numerous, cordate-clasping and hairy-tufted at base, 2–3 in. wide on main st.: panicle 1–2 ft.; spikelets 6 lines long. G. 2:419. Gn. 1, p. 391; 3, p. 493; 8, p. 199; 17, p. 407; 27, p. 307. G.M. 50:253. G.W. 2:337; 3:416; 8:613.—Cult. for ornament because of the regularly placed lvs. and the large plumes. A smaller less hardy variegated form with white-striped lvs. is cult. under the name of var. *variegata* (var. *versicolor*; var. *picta*). G. 18:137. Var. *macrophylla* has large glaucous lvs.

**conspícua**, Forst. f. Sts. lower and more slender: blades long and narrow, 2–4 ft.: panicle 1–2 ft., silvery or yellow-white; spikelets 1–3-fld. B.M. 6232. F. 1874:61. G. 1:344; 9:64; 19:21. Gn. 49, p. 229; 66, p. 121. G.M. 55:408. G.W. 15:51. Native of New Zealand.—Less hardy than *A. Donax*.

A. S. HITCHCOCK.

**ÁSARUM** (ancient obscure name). Including *Hexastylis*. *Aristolochiææ*. ASARABACCA. Low, nearly stemless herbs, sometimes planted in wild borders and used as ground-cover in shady places.

Perennial: sts. creeping, with odd purplish or brown fls. on the surface of the ground (or nearly so), underneath the heart-like or kidney-like lvs.: corolla wanting or merely rudimentary, but calyx corolla-like, with a regular 3-parted limb; stamens 12, with tips on the filaments projecting beyond the anthers: ovary inferior, maturing into a rather fleshy globular caps.—A dozen or more species in the temperate parts of the northern hemisphere. The asarums inhabit rich, shady woods, spreading on the ground, and the fls. are unseen except by the close observer. They are of easy culture if transplanted to rich, moist places. They make attractive carpets in borders and groves. The species described are sold by dealers in native plants. Some of the species are reported to have medicinal properties. Several species of doubtful validity have been described from the southern states.

396. *Arundo Donax*.

395. *Arum italicum*. (×¼)

A. *Plant markedly pubescent.*

**canadense**, Linn. WILD GINGER. CANADA SNAKE-ROOT. Lvs. about 2 to a plant, thin, kidney-shaped, pointed, with a deep and open sinus, not mottled: fl. slender-stalked, with lance-acuminate calyx-lobes an inch or more across at the expanded mouth, chocolate-brown; style 6-lobed. Frequent in woods E. B.M. 2769. A.G. 13:517.

**Härtwegii**, Wats. Tufted, loose-pubescent: lvs. large and thick, cordate, with rounded basal lobes, mostly acute at the apex, margin ciliate, glabrous and mottled above: fl. stout-stalked, the lobes often ovate and long-pointed, the ovary inferior; styles 6. Sierra Nevada, 4,000–7,000 ft. altitude.

**europæum**, Linn. Lvs. kidney-shaped, evergreen, dark green, the petiole 3–5 in.: fls. greenish purple,  $\frac{1}{2}$  in., with incurved lobes; styles 6, and grooved or 2-parted, recurved. Eu.

AA. *Plant slightly or not at all pubescent.*

**caudatum**, Lindl. WILD GINGER. Rather slender, with long rootstocks, sparingly pubescent: lvs. cordate-kidney-shaped, and more or less cupped or cucullate, acute or obtusely: fls. slender-stalked, the calyx-lobes oblong or triangular and attenuate; styles united. Pacific coast.—Evergreen.

**Lémmonii**, Wats. Like the last, but lvs. plane or flat, rounded at apex, less pubescent, calyx-lobes short. Sierra Nevada.

**virginicum**, Linn. Lvs. broad-ovate or orbicular, rounded at the top, the sinus narrow: fl. short-stalked, purple, the calyx-lobes broad and rounded; styles 6, 2-lobed; anthers not pointed. Va., S. in mts.

**arifolium**, Michx. Lvs. thickish and usually mottled, orbicular to hastate, obtuse: fls. stout-stalked, urn-shaped and much contracted at the throat; styles 6, 2-lobed; anthers pointed. Va., S.

L. H. B.

**ASCLEPIAS** (ancient Greek and Latinized name). *Asclepiadaceæ*. MILKWEED. SILKWEED. Perennial milky-juiced herbs, sometimes used in the hardy border or wild garden.

Erect, with deep thick and hard perennial roots: lvs. opposite or verticillate (rarely alternate), entire: fls. gamopetalous, the corolla segms. generally strongly reflexed; stamens 5, attached to the corolla, the anthers more or less united about the stigma; between the corolla and the stamens is a crown of 5 cornucopia-like horns or appendages; pollen cohering into a waxy mass (pollinium) which is removed bodily by insects that visit the fl.: fr. 2 warty, or echinate or smooth follicles.

The pollination of an asclepias fl. is shown in Fig. 398. The pollen-masses are usually twin (as at *b*), and the handle or caudicle lies in a chink on the side of the stigma. The pollen-masses become attached to the legs or mouth parts of the insect, and are thereby transferred to another fl.—The milkweeds are common in waste places in N. Amer., and are rarely cult. About 80 species are known, mostly North American, but others in Cent. and S. Amer. and Afr. Several species (described below) have been offered by dealers in native plants. The butterfly-weed and some others are very showy and worthy of more general attention. The large-lvd. kinds are desirable when heavy foliage effects are wanted. They are all perennials of the easiest cult. Prop. by division, rarely by seeds.

A. *Fls. (corolla and crown) orange.*

**tuberösa**, Linn. BUTTERFLY-WEED. PLEURISY ROOT. Fig. 399. Hairy, 2–3 ft. high, from long, horizontal roots, with more or less alternate, lance-oblong or lance-linear lvs.: umbels several, short-peduncled: pods pubescent, erect. Dry banks and fields; widespread, and not infrequent. B.R. 76.—A handsome plant.

AA. *Fls. in shades of red or purple.*

**Curassávica**, Linn. Plant glabrous, 2 ft. or less: lvs. opposite and short-petioled, thin, oblong-lanceolate: corolla scarlet: pods glabrous, erect. Fla. and La. B.R. 81.

**incarnata**, Linn. Glabrous or nearly so, leafy and branching, 3 ft.: lvs. opposite, oblong-lanceolate: corolla rose-purple to flesh-color, with oblong lobes: pods glabrous, erect. B.R. 250. Var. **púlchra**, Pers. Hirsute, and lvs. broader. Swamps.—Common.

AAA. *Fls. greenish, yellowish or white (sometimes purple-tinged, especially in A. quadrifolia).*

B. *Pods tomentose and soft-spiny.*

**speciosa**, Torr. (*A. Douglasii*, Hook.). St. stout and simple, 3 ft. or less, fine-tomentose or becoming glabrous: lvs. large and broad, ovate, transversely veined, short-petioled: fls. purplish and large, the peduncle of the umbel shorter than the lvs. Neb. W. and S. B.M. 4413.

**Cornùtii**, Decne. (*A. syriaca*, Linn.). Differs from last in having obtuse and short hoods to the crown, taller, less pubescent: lvs. oblong or oval: fls. dull purple, in large, more or less nodding umbels. Mn. 7:221.—The common milkweed of the eastern states.

BB. *Pods glabrous and unarmed.*

c. *Fruiting pedicels decurved or deflexed, the pods erect or ascending.*

**amplexicaulis**, Michx. Plant glabrous and glaucous: st. decumbent, 1–2 ft. long: lvs. numerous, cordate-ovate and clasping, obtuse, succulent: corolla green-purple. Barrens, N. C. and S.

**phytolaccoides**, Pursh (*A. nivea*, Sims). Plant glabrous and green, 3–4 ft., erect: lvs. thin, oval to lance-oval, acuminate and short-petioled: fls. greenish, in large, loose umbels. Moist ground; frequent. B.M. 1181.

**Hállii**, Gray. Stout, puberulent: lvs. thickish, ovate-lanceolate or oblong (3–5 in. long), short-petioled: fls. greenish white and purple, in few many-fl. umbels. Colo. G.C. III. 28:183.

398. Milkweed flower, showing pollination.

397.  
Plume of *Arundo*  
*Donax*. ( $\times \frac{1}{8}$ )

*variegata*, Linn. Two ft. or less high: lvs. 3-7 pairs, oval, ovate or oblong, thinnish, green and glabrous above and pale beneath: fls. white and pink, in 1-3 umbels. Dry, shady places, central and southern states. B.M. 1182.

*ericiarpa*, Benth. Densely woolly all over: lvs. alternate or in 3's, long-oblong or lanceolate, short-petioled: fls. dull white, in few or several umbels. Calif.

cc. *Fruiting pedicels erect, and the pods erect.*

*quadrifolia*, Linn. About 2 ft., not branched, with lvs. towards the top of the st. in whorls of 4: lvs. ovate or lance-ovate, acuminate, thin, nearly or quite glabrous: fls. pink to white in 2-4 loose umbels. Dry soil; frequent. L.B.C. 13:1258.

*verticillata*, Linn. About 2 ft., slender, very leafy: lvs. in whorls of 3-6, very narrow-linear and revolute: fls. greenish white, in many small umbels. Dry soil; frequent. L.B.C. 11:1067.

Var. *pumila*, Gray. A few inches high from a fascicled root: lvs. filiform, crowded. Plains, W.

*mexicana*, Cav. Height 5 ft. or less: lvs. in whorls of 3-6, or sometimes opposite or fascicled, linear or narrow-lanceolate: fls. greenish white or purplish in dense, many-fl. umbels. Ore., W. and S. L. H. B.

399. *Asclepias tuberosa*. ( $\times \frac{1}{4}$ )

G.F. 5:257 (adapted in Fig. 400). Mn. 3:65.

*stans*, Michx. ST. PETER'S-WORT. Tailer, scarcely branched: st. 2-edged, stout: lvs. thicker, broad-oblong or oval and clasping: petals obovate; styles 3-4.

L. H. B.

ASH: *Frazinus*.

ASÍMINA, (from *Assiminier*, a French-and-Indian name). *Annonaceæ*. PAPAW (the papaw of literature is *Carica*, which see). Small trees or shrubs, grown chiefly for their handsome large foliage and for their attractive flowers; also sometimes for their edible fruit.

Low shrubs, and 1 species a small tree: lvs. alternate, usually deciduous, entire: fls. axillary, solitary or few, nodding, short-stalked; sepals 3, smaller than petals,

400. *Ascyrum hypericoides*. ( $\times \frac{1}{2}$ )

deciduous; petals 6, the inner ones smaller, usually upright; stamens numerous, crowded, with short filaments; pistils 3-15, separate, 1-celled with many ovules: fr. consisting of 1 or few oval to oblong berries with rather large compressed seeds in 1 or 2 ranks.—Eight species in E. N. Amer. Description of all species is given in Gray, Syn. Fl. N. Amer. I, pt. 1, pp. 62 and 464.

Asiminas are ornamental trees or shrubs with handsome large foliage, of disagreeable odor when bruised, conspicuous white or purplish flowers in early spring and large edible fruits in autumn. Only two species are cultivated, of which the arborescent one is the hardier and the handsomer in foliage, while the more tender *A. grandiflora* has larger and showier flowers.

They grow best in rich and moist soil. They transplant with difficulty. Propagation is by seeds sown in autumn, or stratified and sown in spring, or by layers in autumn; also by root-cuttings. In the North, the seeds should be sown in pots or pans.

*triloba*, Dunal (*Annona triloba*, Linn.). Fig. 401. Small tree, 10-40 ft.: lvs. cuneate, obovate-oblong, acute,  $\frac{1}{2}$ -1 ft. long, glabrous: fls. with the lvs. from branches of the previous year, green when expanding, changing to purplish red, with yellow in the middle, 2 in. broad: fr.

401. *Asimina triloba*. ( $\times \frac{1}{4}$ )

oblong, 2-6 in. long, dark brown. *S. states*, north to N. Y., west to Mich. and Kan. S.S. 1:15, 16. B.M. 5854. Gn. 33, p. 321. G.F. 8:495. A.G. 44:713. R.H. 1911, pp. 134, 135.—This is the only arborescent species of the genus. It is well worth a place in the garden, for its large foliage is very handsome and the fls., appearing in the early spring, are attractive. The large fr. is edible, and may be still improved by cult. and careful selection of the best varieties. Many persons do not relish the highly aromatic flavor; and the large seeds are a disadvantage. The tree has proved hardy in Mass. and Ont. One or 2 named forms have been offered.

*grandiflora*, Dunal. Shrub, 2-6 ft.: lvs. cuneate, obovate or oblong, obtuse, 2-4 in. long, rufous-pubescent when young, at length glabrous and chartaceous: fls. large, appearing with the lvs.; outer petals cream-colored, over 2 in. long, much larger than the inner ones: the large fr. is said to be very delicious. *S. Ga.*, Fla.

ALFRED REHDER.

**ASPARÁGUS** (the Greek name). *Liliaceæ*. ASPARAGUS. SMILAX (greenhouse). ASPARAGUS FERN. A large genus of herbaceous perennials and tender woody shrubs and vines, grown mostly for ornamental habit and foliage, but one of them (*A. officinalis*) for food.

Plants provided with short underground rhizomes from which the aerial sts. arise in serial order: roots often tuberous, sometimes fleshy but long-cylindric as in *A. officinalis*: sts. varying from low herbs to stout woody vines 50 ft. or more long: lvs. reduced to scale-like bracts usually with a basal spur, often spiny; lf.-function performed by special sterile twigs, cladodes (phyllodia, cladophylls, i.e., lf.-like branchlets) of determinate growth and of characteristic shape with each species (see Fig. 411): fls. usually axillary, or terminal, in 1-4's, sometimes umbellate, often racemose on special branches lacking the cladodes, small; perianth 6-parted; stamens 6, free, filament attached to base of perianth lobes; ovary 3-celled, stigma 3-parted (except in Section *Kodiastigma*), ovules 2-6 in locule: fr. a berry 1-, 3-, 6- or more seeded; seed globose or flat on one side, testa usually black, embryo straight, surrounded by a hard endosperm.—About 150 species, all native of the Old World, ranging from Siberia to Cape of Good Hope, usually from dry regions. Monogr. by Baker, Journ. Linn. Soc. 14 (1875); account of cult. species by Watson, G.C. III. 23:122, 147, 178.

This large genus is remarkable for its lack of functional leaves, whose place is taken by the leaf-like cladodes which are usually considered as leaves. The cladodes are usually borne in fascicles of three to forty in the axils of the leaf-scale; in *A. asparagoides* the leaf-like cladode is solitary in the axils. The woody members of the genus often have the base of the leaf-scale developed into a strong spine. In some groups the cladodes are spiny tipped. *A. stipulaceus* and its relatives (apparently not in cult.) have the side branches developed into thorns.

Most of the ornamentals of the genus will not stand frost, but some of the Asiatic forms are perfectly hardy except in the North. Members of this genus furnish the most satisfactory "green" for decorative purposes known to the trade, some of the forms rivaling the finest ferns in their delicate beauty. Their ability to hold up for several days without wilting makes the cut sprays of some of the species necessary in some forms of decorative work.

Nearly all the species are of easy cul-

ture and can be propagated readily by seed which is usually produced in abundance; also propagated by division and in some woody forms by cuttings.

#### KEY TO THE SPECIES.

- A. *Lf.-scales with a basal spur or scale: cladodes fascicled in axils of lf.-scales and, when flat, with stomata on both sides.*
  - B. *Fls. diæcioous: fl.-buds axillary and present on young shoots, developing with the cladodes.*.....Section **EUASPARAGUS**
    - C. *Cladodes filiform.*
      - D. *Plant an erect herb: cladodes terete.*.....1. *officinalis*
      - DD. *Plant a semi-woody vine: cladodes angled.*.....2. *verticillatus*
    - CC. *Cladodes flat, linear or linear-lanceolate.*
      - D. *Berry black: cladodes falcate, ¼-½ in.; branches with twigs and cladodes in a horizontal plane: fls. opening widely: an erect herb*.....3. *filicinus*
      - DD. *Berry white or pink: cladodes nearly straight, 1-2 in., not in a definite plane: a vine.*.....4. *lucidus*
  - BB. *Fls. perfect, usually appearing after the cladodes or on special branches on the old wood.*
    - C. *Base of lf.-scale a spur, often a sharp spine: fls., when solitary, in axils with cladodes.*.....Section **ASPARAGOPSIS**
      - D. *Position of fls. axillary or terminal, with cladodes.*
        - E. *Cladodes filiform or 3-angled.*
          - F. *The fls. not umbelled, 4 or less.*
            - G. *Shape of cladodes 3-angled, in 3's: fls. axillary: an herbaceous vine, tuberous-rooted.*.....5. *crispus*
            - GG. *Shape of cladodes terete, numerous: fls. terminal: woody vines, not tuberous-rooted: branches with twigs pinnate in a horizontal plane.*
              - H. *Lf.-scales white or whitish, spine deltoid: sts. slender, smooth.*.....6. *plumosus*
              - HH. *Lf.-scales red-brown, spine terete, strong and sharp: sts. thick, with short pubescence.*.....7. *Cooperi*
          - FF. *The fls. in umbels.*
            - G. *Plant a slender green-stemmed vine: cladodes 3-8.*.....8. *umbellatus*
            - GG. *Plant stiff gray-stemmed shrubby climber: cladodes 10-20.*.....9. *retrofractus*
        - EE. *Cladodes flat.*
          - F. *Berry 3-lobed: cladodes lanceolate: fls. terminal: erect shrub, 1 ft.*.....10. *madagascariensis*
          - FF. *Berry globose: cladodes linear-falcate: fls. axillary: a delicate vine*.....11. *scandens*
          - DD. *Position of fls. in racemes on old wood.*

1. *officinalis*, Linn. **ASPARAGUS**. Figs. 402, 403. An erect herb from a woody crown with long fleshy roots: sts. smooth, much branched above, 4-12 ft. high: cladodes 3-8 in a fascicle,  $\frac{1}{4}$ -1 in. long, terete: lf.-scale with a short soft spur at base: fls. 1-4, in axils with cladodes or branches, campanulate, yellowish green: berries red,  $\frac{1}{4}$ - $\frac{3}{8}$  in., 1-9-seeded; seed germinate in 12-14 days in warmhouse, often taking a month when planted outdoors in spring. Eu.—The esculent asparagus of the garden, the fruiting sprays with the bright red berries used for decorating. The young seedlings developed from a large number of seed planted in a small pot or pan make a very handsome table decoration. See *Asparagus*, *Esculent*.

2. *verticillatus*, Linn. A semi-woody climbing vine from a woody rootstock: roots long-cylindric, fleshy: sts. stout ( $\frac{1}{2}$  in.), 10-15 ft. long, edible when young: branches green, angled, flexuose: cladodes 3-8,  $\frac{3}{4}$ -2 in. long, angled, filiform, not stiff: lf.-scales of main st. developed below into spines: fls. funnel-shaped in 1-4's in axils of lf.-scales: berries red,  $\frac{1}{4}$  in. diam., 1-3-seeded. Persia to Siberia. R.B. 20:154. G.W. 14:648. G.Z. 24:505.—A hardy ornamental climber; grows readily from seed, which germinates in about 3 weeks in a warmhouse; plants slow-growing at first.

404. Flower of *A. plumosus*. Typical of *Asparagopsis*.

405. *Asparagus plumosus* var. *nanus*. (X $\frac{1}{4}$ )

3. *filicinus*, Ham. An erect herb with densely clustered fusiform tuberous roots 2-4 in. long: sts. erect, branching: branches with twigs and cladodes in a horizontal plane like *A. plumosus*: cladodes flat, lanceolate strongly falcate, 3-5, of varying lengths,  $\frac{1}{4}$ - $\frac{5}{8}$  in.: fls. axillary on long slender pedicels, green; stamens and pistils white; perianth-lobes wide-spreading: berry black,  $\frac{3}{8}$  in., 1-3-seeded. India and China. G.C. III.

44:122, 123.—Hardy herbaceous perennial, very ornamental, suggesting a delicate fern in appearance; several wild varieties.

4. *lucidus*, Lindl. Semi-woody climber, 6-10 ft., few main branches: roots tuberous, 2-6 in. long: cladodes 3-5, flat curved linear about 1 in. long: lf.-scale on main st. with a short spine: fls. small, white, 1-4, in axils with cladodes: berries pink or white,  $\frac{1}{4}$  in. diam. China, Japan and Formosa. A.G. 13:78.—Probably hardy in most of U. S. Tubers edible.

5. *crispus*, Lam. (*A. decumbens*, Jacq., and Hort.). Roots tuberous, short, densely clustered about crown: sts. herbaceous, green, weak, climbing or drooping, 3-6 ft., much branched: branches deflexed, and zigzag: lf.-scale developed below into a weak spur: cladodes 3, 3-angled, reflexed, about  $\frac{1}{4}$ - $\frac{3}{8}$  in. long: fls. on slender drooping pedicels, axillary, solitary, or in pairs, white, sweet-scented, resembling the fls. of *A. asparagoides*: berry white or pink,  $\frac{1}{2}$  in., several-seeded, seeds small, black. S. Afr. A.F. 16:825.—Easily grown from seed or prop. by division; a beautiful plant for hanging-baskets. This species is often sold under the name of *A. scandens deflexus*, Baker, which has flat cladodes and 1-3-seeded, red berries.

6. *plumosus*, Baker. **ASPARAGUS FERN**. Fig. 404. Woody, tall climbing vine: roots not tuberous, long, slightly fleshy: st. terete, green, glabrous: branches with twigs and cladodes arranged in a horizontal plane, making a compound pinnate frond, triangular in outline: cladodes numerous, 8-20 in a fascicle,  $\frac{1}{4}$  in. or less long, slender, terete, bright green: lf.-scale white or gray, on main st. developed below into a woody deltoid spine: fls. 1-4 at ends of twigs, white; perianth-lobes spreading obovate, blooming in autumn: berry 1-3-seeded, purple-black. S. Afr. F. 1882:101. F.R. 4:93. F.S. 2413-14. G. 25:110. G.C. II. 13:749; III. 23:146. G.Z. 25:2. A.F. 11:1178.—A popular decorative plant now almost superseded by some of its varieties. The cut sprays and strings of *A. plumosus* and its varieties are used in large quantities by florists on account of their beauty and keeping qualities. Most of the forms are prop. by seed or division but some are readily increased by means of cuttings. Var. *comorensis*, Hort. (*A. comorensis*, Hort.). Similar to *A. plumosus* but more robust: cladodes lighter green, more open and delicate in their arrangement: frond widely triangular, very regular. A.F. 18:684. F.E. 14:462. F.R. 9:877. G.C. III. 23:181. Gng. 10:295. I.H. 42:61. S.H. 1:84. V. 20:101. Var. *nanus*, Hort. Fig. 405. The common commercial variety of the species: cladodes more numerous and shorter than type, making the horizontally spreading fronds more dense: sts. often short, making a short spray rather than a vine: easily reproduced by seed, which germinate in three weeks. Var. *tenuissimus*, Hort. (*A. tenuissimus*, Hort.). Fig. 406. A wiry stemmed variety with fewer cladodes longer than in type and not so much in a horizontal plane, distinctly glaucous blue-green; not a strong climber. Var. *robustus*, Hort. A ranker-growing vine with shorter cladodes than type, side branches making longer and more irregular fronds than *A. plumosus nanus*, a duller green. *A. plumosus superbus*, Hort., *A. Blampiedii*, Hort., and *A. Hatcheri*, Hort. (F.E. 31:935), are all botanically closely related if not identical with *A. plumosus robustus* and with it are separated from the other forms of the species by their stronger growth and by the much less regular arrangement of the cladodes and twigs into a horizontal plane. Var. *compactus*, Hort. A dwarf form, said to be a hybrid between *A. plumosus nanus* and *A. plumosus tenuissimus*, suitable for pot-plants. F.E. 16:637 See Fern, *Asparagus*.

7. *Coëperi*, Baker. Roots long, cylindric, more or less fleshy: sts. large, up to  $\frac{3}{4}$  in. diam. and 60 or more ft. long, branching above; main sts. and branches very dark green, with a soft, very short pubescence: cladodes very dark green,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long, 5–12 in a cluster, much stouter than in *A. plumosus*: final branches with twigs and cladodes making beautiful pinnate fern-like sprays  $\frac{1}{2}$ –3 ft. long: lf.-scale swollen at base, red-brown,

406. *Asparagus plumosus* var. *tenuissimus*. ( $\times \frac{1}{4}$ )

with a strong spine: fls. small, white, bell-shaped, sweet-scented; berry about  $\frac{1}{4}$  in. diam., red. S. Afr. G.Z. 21: 568, 569.—This species is probably the largest one in the genus, its long vines covered with beautiful dark green sprays making a very desirable cover for pillars. The side sprays are valuable for cut-green for florists' use and, when removed, a second crop will appear shortly on the old vines.

8. *umbellatus*, Link. A spreading climber or undershrub: sts. terete, slender, scabrous, dark green, woody below, branching: branches and twigs often reflexed and pendulous: cladodes 3–10, terete,  $\frac{3}{4}$ –1 in. long, very dark green: fls. in axillary or terminal umbels; pedicels  $\frac{1}{2}$  in. long, perianth largest of genus,  $\frac{1}{8}$ – $\frac{1}{2}$  in. spreading, white; segms. elliptic-obtuse; stamens dark yellow: berry globose, yellow to dark red. Canary Is. and Madeira. B.M. 7733. G.C. III. 28:379.—The large, sweet-scented fls. produced abundantly in midsummer; a good plant for pillar decoration; grows well from seed.

9. *retrofractus*, Linn. (*A. retrofractus arboreus*, Hort.). Sts. slender (6 or more ft.), becoming woody and gray, scarcely climbing, zigzag, the branches wiry: cladodes in close clusters, green, filiform, about 1 in. long: lf.-scale bases spiny: fls. in umbels, small, white: berry small, nearly globose, 1-seeded. S. Afr. Gn. 59:111.

10. *madagascariensis*, Baker. Erect, much-branched shrub, 1 ft. or more, suggesting *Ruscus aculeatus*: sts. green, angled: cladodes 3, lanceolate, pointed, glabrous, dark olive-green, often arranged on the twig in one plane making a pinnately compound lf. in appearance,  $\frac{3}{8}$ – $\frac{5}{8}$  in. long: base of lf.-scale not spiny: fls. creamy white, normally in 4's at end of twigs,  $\frac{1}{4}$  in. diam.: berry scarlet, 3-lobed, 1–3-seeded. Madagascar. B.M. 8046.—A good pot-plant, especially in winter when it is well set with scarlet berries. Thrives in either a hot or temperate greenhouse, easily prop. from seed, which are freely produced.

11. *scandens*, Thunb. A slender climbing vine up to 6 ft.: sts. green, branching freely above; branches with twigs and cladodes in one plane, suggesting *A. filicinus* somewhat: cladodes flat, long, lanceolate-falcate, 3–5 in.: fascicle  $\frac{1}{4}$ – $\frac{1}{2}$  in. long, central one longest, glabrous, light green: lf.-scale minute, base not spined: fls. pendulous, solitary or paired in axils, greenish white,  $\frac{1}{2}$  in. diam., perianth spreading, segms. elliptic-oblong: berry

globose,  $\frac{1}{8}$  in. diam., red, 1-seeded. S. Afr. B.M. 7675. G.C. III. 33:339.—One of the weaker-growing kinds of ornamental asparagus, thriving well in an intermediate house. A good decorative plant when grown in strings for table decoration; also good as a pot-plant. Var. *deflexus*. Similar to type but with branches deflexed: cladodes stiffer and smaller: fls. smaller: seed often white. G.W. 5:446; 13:301. *A. crispus* is often sold under this name, but is easily distinguished by its 3-angled cladodes (see discussion under No. 5).

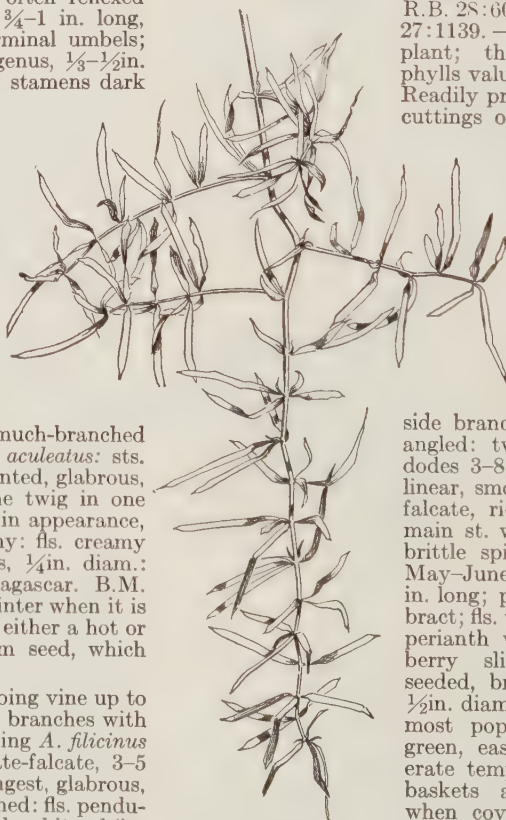

12. *tetragonus*, Bresler (*A. racemosus tetragonus*, Baker). A climbing vine, 15–20 ft. high: roots tuberous, elliptic, 1–2 in. long: sts. gray to brown, branching above: cladodes 3–8, usually 5, 3–4-angled,  $\frac{1}{8}$ – $\frac{5}{8}$  in. long, dense; more or less falcate: lf.-scale on main st. with a strong recurved basal spine up to  $\frac{1}{2}$  in. long: fls. in racemes 2–3 in. long, on old wood; perianth white or pink,  $\frac{1}{4}$  in. diam., segms. obovate-obtuse; fls. fragrant. S. Afr. B.M. 8288. G.C. III. 23:147.

13. *drepanophyllus*, Welw. (*A. Duchénei*, Linden). A tall climbing woody vine with tuberous roots 2–3 ft. long: sts. 20–30 ft. long, terete, without main branches: axillary twigs and cladodes making a compound cladophyll from upper axils: twigs  $\frac{1}{2}$ –2 ft. long, thick-set with cladodes in fascicles of 3–5: lf.-scales on twigs 5-ranked but cladodes turned into a horizontal plane: central cladode 2–3 in. long, lateral  $1\frac{1}{2}$  in., the compound cladophyll suggesting a frond of *Asplenium*: lf.-base with a strong spine: fls. in dense erect racemes, 3–8 in. long; pedicels deflexed in fascicles of 3–8; perianth greenish, bell-shaped, not opening widely: berry rare, 3-lobed, usually 1-seeded,  $\frac{1}{2}$  in. diam., bright scarlet, ripe in 90–120 days after the bloom. Oct.–Jan. S. Cent., Afr., Congo region. G.C. III. 28:305. R.B. 28:60. Gng. 15:131. A.F. 27:1139.—A highly decorative plant; the compound cladophylls valuable in florists' work. Readily prop. by division or by cuttings of the twigs taken off

with a heel, or piece of the main st. attached and put in a sandy soil in a close case with bottom heat.

14. *Sprengeri*, Regel. Figs. 407, 408. Roots tuberous, white, elliptic, not densely clustered: sts. numerous, scarcely climbing, 6 ft. or less:

side branches numerous, small, angled: twigs 1–3 in. long: cladodes 3–8,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. long, flat, linear, smooth, pointed, slightly falcate, rich green: lf.-scale on main st. with a slender brown brittle spine  $\frac{3}{8}$  in. long: fls. in May–June, in open racemes 1–3 in. long; pedicels 1–2 from each bract; fls. whitish pink, fragrant, perianth wide-spreading,  $\frac{1}{8}$  in.: berry slightly 3-lobed, 1–3-seeded, bright coral-red, up to  $\frac{1}{2}$  in. diam. Natal.—One of the most popular plants for cut-green, easily grown in a moderate temp. Plants in tubs or baskets are very ornamental when covered with the bright red berries which ripen about Christmas-time. Easily grown

407. *Asparagus Sprengeri*. ( $\times \frac{1}{2}$ )

from seed, which germinates in a temperate house in about 4 weeks. The best asparagus for a house plant. A.G. 18:86, 883; 19:101. B.M. 7728 (as *A. ternifolius*), 8052. F.E. 9:11. F.R. 4:95. G. 21:123. Gn. 54, p. 88; 58, p. 109. G.L. 17:175. Mn. 8, p. 151. Gn.W. 20:117; 23:607. G.W. 4, p. 109; 13, p. 462. Gng. 4:167. G.C. III. 37:10. Var. **compactus**, a dwarf variety seldom over 18 in. long. Var. **variegatus**, a form having variegated lvs; otherwise like the type. Gn. 59:145. F.E. 14:885. Var. **falcatus**, a large strong-growing form: phylloclades solitary to 5-6 more or less falcate. *A. sarmentosus*, Hort., not Linn., is a short compact form of *A. Sprengeri*. The true *A. sarmentosus* is quite a different plant and not in cult.

408. Strong new shoot of *Asparagus Sprengeri*. ( $\times \frac{1}{2}$ )

15. **falcatus**, Linn. A large spreading woody vine with stout gray or brown sts. 20-40 ft. long, much branched above: cladodes 3-5, or more at ends of twigs, falcate, linear-lanceolate, with undulate margins, rich dark green, 2-3 in. long: lf.-scales with stout basal spines: sweet-scented fls. in loose racemes 2-3 in. long, produced in great profusion in midsummer; perianth pure white,  $\frac{1}{4}$  in. diam., segms. lanceolate; stamens yellow: fr. dull brown. Trop. Asia and Afr.—One of the largest and finest species of the genus; thrives under temperate conditions, growing outdoors in the absence of frost. G.C. III. 23:123; 41:82. Ref. Bot. 261. G.W. 5:334.

16. **virgatus**, Baker (*A. elongatus*, Hort.). Fig. 409. Roots fibrous, crown with long semi-woody rhizomes: sts. erect (3-6 ft.), much branched above, branches long, straight or drooping: cladodes in 3's, stiff,  $\frac{1}{4}$ - $\frac{3}{4}$  in. long, angled, not very abundant; cladodes and sts. dark green: lf.-scale white, developed basally into an appressed bract-like extension similar to upper part: fls. solitary at nodes on drooping pedicels, no cladodes in axils with fls.; perianth greenish white, wide-spreading,  $\frac{1}{8}$  in. diam.; stigma capitate: berry 1-2-seeded, dull orange-red,  $\frac{1}{4}$  in. in diam. S. Afr. F.E. 27:114.—Easily grown from seed, which germinates in 3 weeks, or from cuttings of rhizomes. Not highly ornamental, but of value in decorative work on account of its erect habit.

409. Flower of *Asparagus virgatus*. Typical of *Kodiastigma*.

17. **asparagoides**, Wight (*Myrsiphyllum asparagoides*, Willd. *A. medeoloides*, Thunb.). **SMILAX** of florists. Fig. 410. Tall slender glabrous twiner: sts. slender, much branched: cladodes single in axils of lf.-scales, ovate, about 1 in. long, usually spreading horizontally: lf.-scale small, not developed into a spur at base: fls. solitary or paired in axils on slender pedicels, greenish white; perianth-lobes spreading or recurved from beyond middle: berries dark purple, 1-3-seeded. S. Afr. B.M. 5584. R.H. 1895: 177. S.H. 1:417; 2:160. Gn. 42, p. 536. G.W. I, p. 206.—Much grown for florists' use in decorations. Seed small, germinating in about 3 weeks (see cultural notes under *Smilax* in a succeeding volume). Var. **myrtifolius**, Hort. "BABY" **SMILAX**, an extremely light and elegant variety with much smaller lvs. than the type, becoming popular.

*A. acutifolius*, Linn. Semi-hardy, becoming a woody shrub in the S., zigzag, branching, 5 ft.: cladodes short, stiff, terete, spiny-tipped in fascicles of 5-12,  $\frac{1}{4}$  in. long: fls. dioecious, yellow; berry waxy olive-green.—A dark green cedar-like ornamental. *Medit. region.*—*A. ethiopicus*, Linn. Tropical vine: cladodes 3-5 ft., linear falcate, 1-2 in. long: lf.-base spiny: fls. in racemes, near *A. Sprengeri*. S. Afr.—*A. africanus*, Lam. Woody semi-climber, spiny: cladodes filiform-terete, stiff, dark green, up to 20 in a cluster 1 in. long: fls. in umbels. S. Afr.—*A. albus*, Linn. (*A. Pastorianus*, Webb & Berth.). A white-stemmed branching woody shrub, semi-hardy, 3-4 ft. high: cladodes densely fasciated, 1 in. long: lf.-scale with a long sharp spine: fls. in umbels. *Medit. region.*—Very susceptible to attacks of red-spider. G.Z. 1907:31.—*A. asiaticus*, Linn. A tall branching woody vine: cladodes numerous in clusters, soft-filiform,  $\frac{1}{2}$  in. long: fls. in umbels. S. Afr.—*A. declinatus*, Linn. Allied to *A. plumosus* but with cladodes about  $\frac{1}{2}$  in. long: branches slender, drooping: fls. axillary, small, white: berries 1-seeded. S. Afr.—*A. larinicus*, Burch. A woody shrub suggesting *A. retrofractus* but with cladodes 1 in. long. S. Afr. G.C. III. 23:122.—*A. longipes*, Baker. A copiously branched undershrub with subterete slender green cladodes  $\frac{1}{2}$ -1 in. long in whorls of 9-12: fls. axillary, solitary or paired. S. Cent. Afr.—*A. myriocladus*, Hort. (*A. Greenfieldii*, Hort.). An erect, much-branched shrub, 6 ft., with tuberous roots: st. gray: branches zigzag with dense clusters of light green filiform cladodes  $\frac{1}{2}$  in. long, becoming dark green with age.—Very ornamental: fls. unknown, but it is closely related in type to *A. retrofractus*. *Natal. G.* 25:293; 33:435. Gng. 12:547. F.E. 16:637. The true *A. myriocladus*, Baker, is related to *A. Sprengeri* and has flat cladodes and racemose fls. This species is apparently not in cultivation.—*A. oligoclados*, Maxim. Erect, hardy herbaceous perennial suggesting *A. officinalis*: cladodes more dense, slender and graceful: 1-2 ft.: fls. dioecious, campanulate. N. Asia.—*A. schobertoides*, Kunth. Erect, hardy herbaceous perennial, 1-3 ft.: roots tuberous: cladodes long, 3-angled, flat, ascending: fls. nearly sessile, dioecious: berries red. Japan and China.—*A. Sieberianus*, Hort. A supposed hybrid

410. *Asparagus asparagoides*, or *Smilax* of florists. (Natural size.)

between *A. crispus* and *A. plumosus tenuissimus*: sts. slender, rigid, with slightly curved cladodes. Distinct and valuable as a market plant.—*A. tenuifolius*, Lam. Herbaceous perennial: like *A. officinalis*, with very slender, numerous cladodes and large bright red berries. S. Eu.—*A. trichophyllus*, Bunge. Hardy herbaceous perennial, somewhat twining, 3-6 ft.: cladodes like *A. officinalis*,  $\frac{1}{4}$ -1 in. long: fls. dioecious (long-campanulate) on drooping pedicels. N. Asia.

J. B. NORTON.

**ASPÁRAGUS, ESCULENT** (*Asparagus officinalis*, Linn.). *Liliaceæ*. A perennial herb, cult. for the succulent young shoots that arise from the crown in spring.

Asparagus is native to Europe. It has been cultivated 2,000 years and more. It was known to the Greeks and Romans. The so-called lvs. of asparagus are really leaf-like branches. The lvs. are the scales, which are well shown on the shoot at the left in Fig. 411. From the axils of these scales, branches may arise, *a a*. At *b b* are shown clusters of branchlets, or "leaves," issuing from the axils of scales or lvs.

Being a rugged plant, asparagus will live and in a measure thrive on almost any kind of soil, even under adverse circumstances and when entirely neglected. Occasionally one may find apparently thrifty plants in fence rows, or strong stalks pushing up through stone heaps or other rubbish piled foot-thick upon an old abandoned asparagus bed. Plants on good soil will get so large, and the immense network of roots so well anchored in the soil, that all the strength of a good team may be insufficient to pull them out, and sometimes several years' persistent efforts may be required to clear them out of a piece of ground once used as an asparagus patch. The stalks that the discriminating growers and fastidious consumers want are those an

inch in diameter and deliciously tender and succulent, and these can be grown only on good plants set far enough apart on well-drained, well-manured and well-tilled soil. To secure the choice early stalks that bring the high prices, the land selected for an asparagus patch should be a warm rich loam, preferably exposed to east or south. Manures and fertilizers, also, must be used most lavishly. In this respect, many growers fail to obtain best results, such as are within their reach by greater liberality. Unless the soil is already well supplied with vegetable matter and for that reason very loose and mellow, bulky manures, such as fairly well-rotted stable manure or rich compost, are almost or quite indispensable at the start. A heavy dressing is to be plowed under, and should be well and deeply mixed with the soil by reploting and reworking the land. Afterwards concentrated manures, rich especially in nitrogen and potash, will do very well for loose soils, and may be used broadcast on top, as the crop appears to need them from year to year, at least for a while. Even then an occasional, or better, yearly, application of good stable manure or compost placed in furrows plowed (with a one-horse plow) on each side of the rows after the cutting season or in early fall, will be of benefit or become necessary to keep the yield up to a high mark. To start a plantation in the right way, the selection of good strong one-year-old plants is of much importance. They are usually preferable to the ordinary two-year plants. To grow one's own supply for starting a plantation a year later is usually a safer plan than to depend on purchased plants. The male, or pollen-bearing, plants are often more vigorous and more productive of good stalks than the female or seed-bearing plants; but one cannot very well tell the one from the other unless they bloom, until long after they are already established in the plantation, when it would be impracticable to tear out the less desirable female plants and replace them with the male plants.—The seed, obtainable from any regular seed house, is rather hard-shelled and so netimes slow to germinate. It is important to give the seedling plants the longest possible period of growth so as to secure the strongest possible plants. It is advisable, therefore, to soak the seed, or give it special treatment or seed stimulation, before sowing it, and to sow it just as soon in spring as a rich mellow seed-bed can be prepared. The rows or drills may be made a foot apart, and seed sown rather thinly. Plants are to be thinned to 3 inches apart at an early age, and weeds should be carefully kept down from the very start. In short, nothing should be neglected to prevent any interference with the rapid and healthy growth of the seedlings, for the future outcome hinges, to a great measure, on a favorable early start.—When getting ready to set the plants, and after the land has been carefully and deeply plowed and harrowed, plow out furrows 4 or even 6 feet apart. It may look like a sinful waste of good land to set asparagus so far apart, but even at 6 feet the roots will fill the soil and reach across

the rows, and the fat stalks obtainable by wide planting are worth more in our markets than the inferior ones usually found there. Some markets demand or prefer green stalks which are mainly grown above ground. In that case, make the furrows 5 to 9 inches deep. In other markets blanched shoots are wanted, and these are of superior flavor and tenderness, provided they are grown in mellow soil and under high and skillful culture. In that case, make the furrows a few inches deeper than for plants set for green stalks. Set the plants in the furrows about 2 feet apart, each on a little mound of soil, spreading the roots in the same way as they grew in the seed-bed. Cover with mellow soil to the depth of a few inches, and afterwards, in the course of some weeks and by means of some suitable tools (cultivators, harrows, and the like), gradually fill the furrows even with the ground-level. A still better plan when the material can be had, especially for the home-gardener, is to fill the furrows with fine old compost, wood's earth, leaf-mold, or any other loose and rich material, as the covering above the crowns of the plants cannot be made too loose. It is advisable and will insure closer attention in cultivation, to grow some hoed crop, like beets, turnips, radishes, cabbage, beets, beans or peas, between the rows of asparagus the first year. In the fall, and every fall thereafter, cut the asparagus stalks close to the ground and remove them from the patch, to avoid the scattering of the seed.

In early spring of the second year, the surface of the ground is to be loosened by shallow plowing or deep cultivating; and when the first sprouts appear, the rows may be hilled up to some extent if any of the sprouts are to be cut for use. Under especially favorable conditions a few may be cut the second year. It is better for the plantation and its future value, however, if no cutting is done that year. Plants left intact until the third year, and kept in a high state of cultivation, will grow much stronger and be more productive afterward. Commercial growers use specially devised asparagus knives for cutting the stalks. In the absence of such, any ordinary sharp table or kitchen knife may be used, or in the mellow soil the blanched shoots may be broken off at the base with the finger. In cutting, be very careful, and try to avoid cutting later shoots or injuring the crown of the plants. The third season and every season thereafter, loosen up the ground as directed for the second season. The shoots are now to be cut indiscriminately and clean, up to the beginning of the green-pea season. After that, allow them to grow undisturbed, but continue cultivation, to keep the ground-surface mellow and free from weeds. For market, wash the freshly-cut stalks and tie them in neat, compact bunches of the size demanded in the particular market, using some bright-colored ribbon, or perhaps rubber bands. If to be shipped, especially for longer distances, pack the bunches in moist moss or other material that will keep the stalks fresh.

The varietal differences in the asparagus plant do not appear to be very pronounced except in the color of the young shoots, and most of the variations seem to be due to differences in culture and environment rather than to those characteristic of the variety. American seedsmen offer the following as distinct varieties: Colossal (Conover's), Palmetto, Mammoth (Barr's), Columbian (Mammoth Columbian White), Argenteuil (Giant Argenteuil), Bonvallet Giant, Reading Giant.

To save the seed, strip the ripe berries off the stalks by hand, or thresh them off with a flail, put them in a sound barrel or tank, and mash them with a wooden pounder, to separate the hard, black seeds from the pulp. Clean them by washing in plenty of water, pouring off the pulp and skins; then dry and store.

To any person who has even a little land to use for a home-garden, no better advice could be given than to

plant in a corner or at one side of it 50 or 100 asparagus roots for his family, as no other use of that spot, ordinarily, may be expected to give more real benefit, enjoyment and value. The number of roots named will under average conditions give all the stalks that a large family could use, and several times the quantity that a person of ordinary means would feel able to purchase for the family table in the open market. For the market-gardener, especially one with a regular retail trade, few if any vegetables offer equal chances of profit and regular returns and a sure income at a most opportune time (spring).

**Enemies.**—The asparagus rust (*Puccinia asparagi*) has often done considerable damage. Planting rust-resistant varieties is the best procedure. Argenteuil and Reading Giant afford the best relief. Dusting completely with flowers of sulfur when the dew is on, and after the cutting season, is the best remedy; two applications, three or four weeks intervening, are usually sufficient.

Of insect enemies, two have become well known on asparagus plants in America, namely, the common asparagus beetle (*Crioceris asparagi*) and the twelve-spotted asparagus beetle (*C. 12-punctata*). The following remedies are recommended: chickens and ducks; close cutting of the young shoots in the early season, and the use of arsenate of lead or of dry arsenites dusted on the dew-wet plants after the cutting period.

The subject of asparagus and asparagus-growing is treated in the following books and bulletins: Asparagus, by F. M. Hexamer, Orange Judd Company. Farmers' Bulletin No. 61 (Asparagus Culture), issued by the Department of Agriculture, Washington, D. C. Bulletin No. 151 of the Maryland Station (Fertilizers for Asparagus). Bulletin No. 34 of the Missouri Station (Asparagus and Rhubarb Culture). Bulletins Nos. 165 and 172 of the California Station (Asparagus and Asparagus Rust in California). T. GREINER.

**ASPÀSIA** (Greek personal name). *Orchidaceæ*. Epiphytic hothouse orchids.

Stems thickened into pseudobulbs, 1- or 2-lvd.: racemes lateral; sepals and petals nearly alike, spreading; lip with the claw adnate to the column, the blade spreading; lateral lobes distinct or confluent with the middle lobe; pollinia 2.—Species about 8, ranging from Cent. Amer. to Brazil.

**epidendroides**, Lindl. Pseudobulbs, oblong, 2-edged: lvs. linear-lanceolate: racemes of 2-4 fls.; sepals and petals whitish yellow, streaked with brown; lip white, dotted with purple. Panama. B.M. 3962.

**lunata**, Lindl. Pseudobulbs, 2-edged, oblong: lvs. oblong-ligulate, up to 6 in. long: fls. single, or rarely 2; sepals and petals linear-lanceolate, acuminate, green or yellowish, marked with violet-purple; lip white, marked with purple. S. Brazil.

**variegata**, Lindl. Pseudobulbs ovate or oblong, 2-edged: lvs. lanceolate-ligulate, up to 8 in. long: raceme of 2 or 3 fls.; sepals oblong-lanceolate, acute, greenish or yellowish, marked with interrupted longitudinal black-purple lines; petals obovate-oblong, acute, yellowish veined with purple; lip white, yellowish at the base, spotted with purple. S. Amer. B.M. 3679. B.R. 1907.

GEORGE V. NASH.

**ASPEN:** *Populus*.

**ASPERÉLLA:** *Hystrix*.

**ASPERULA** (roughish; referring to lvs.). *Rubiaceæ*. WOODRUFF. Mostly dwarf hardy herbs, for borders, rock gardens and shady places.

Annual or perennial: sts. square: lvs. whorled (some of the lvs. are really stipules): fls. many, small, mostly 4-parted, produced freely from May to July; corolla funnelform, which distinguishes it from the closely related *Galium* in which the corolla is rotate.—About 80 species in Eu., Asia and Austral.

The commonest species is *A. odorata*, the Waldmeister of the Germans, which is used in their Mai-trunk, or May wine, and in summer drinks. The dried leaves have a hay-like fragrance, lasting for years, and are often kept with clothes. The plant occasionally escapes from gardens. *A. hexaphylla*, with its delicate, misty spray, is used with sweet peas and other cut-flowers that are inclined to look lumpy. Other plants for this purpose are *Gypsophila paniculata*, *Statice latifolia*, and several galiums, all of which have small, abundant flowers in loose panicles on long, slender stems.

In half-shaded and moist soil, asperulas grow very luxuriantly until late fall. In dry and sunny places they soon become stunted, and die down before the season is over.

Propagation is by division and by seeds.

*A. Plants perennial: fls. white or pink.*

*B. Corollas 4-lobed.*

**odorata**, Linn. SWEET WOODRUFF. Fig. 412. Habit erect or ascending: height 6-8 in.: lvs. usually in whorls of 8, lanceolate, finely toothed or roughish at the margin: corollas campanulate: seeds rough. Eu. and Orient. Eng. Bot. 2:775. Baxter Brit. Bot. 1:46.—Increases rapidly, and is used for carpeting shady places, and for edgings.

**Gussònei**, Boiss.

(*A. suberosa*, Guss.).

A glaucous, smooth, usually caespitose perennial suitable only for the rock-garden: lvs. small, in pairs, some ovate-oblong, the rest lanceolate-linear: fls. at the ends of the branches, the corolla smooth and pinkish, not showy. Sicily.—A graceful little alpine.

**hexaphýlla**, All. Plant-st. glabrous: habit ascending, slender: height 1-2 ft.: lvs. in whorls of 6, linear, acute, rough: corollas tubular-funnel-shaped: panicles very loose; fls. larger than the bracts: seeds smooth. Italy, Hungary, Pyrenees on high passes and dry mountainsides.—Well-grown specimens may be 3 ft. in diam. and nearly as high.

**hírta**, Ramond. A many-stemmed hairy perennial, suitable for the alpine garden: sts. 4-sided, with verticillate lvs. in 6's: lvs. linear, 1-nerved: fls. small, pinkish. Rocky situations in the Pyrenees. July, Aug.

*BB. Corollas often 3-lobed.*

**tinctória**, Linn. DYER'S WOODRUFF. Habit procumbent unless supported: height 1-2 ft., the st. purplish: lvs. linear; lower ones in 6's, middle ones in 4's, uppermost ones in 2's: bracts ovate: fls. reddish on outside: roots large, creeping widely, reddish. Dry hills and rocks of Eu.

*AA. Plants annual: fls. blue.*

**orientális**, Boiss. & Hohen. (*A. azurea* and *A. setosa*, Jaub. & Spach. *A. azurea-setosa* and *A. setosa-azurea*, Hort.). Height 1 ft.: lvs. in whorls of 8, lanceolate, bristly: fls. longer than the bracts. Eu. and Orient.

*A. cymánchina*, Linn. 9-12 in., glabrous: fls. corymbose on erect peduncles: lvs. 4 to a whorl. Eu. and Asia.—*A. longiflora*, Waldst. 6-8 in., weak, glabrous: fls. white, yellowish inside: lvs. 4 to a whorl, linear-lanceolate. Eu.—*A. taurina*, Linn. 1 ft., erect, smooth: fls. in fasciculate umbelled corymbs, white: lvs. 3-nerved, ciliate, 4 to a whorl. Perhaps not hardy N. S. Eu.

WILHELM MILLER. N. TAYLOR.]

**ASPHODEL:** *Asphodeline* and *Asphodelus*.

412. *Asperula odorata*. (×1)

**ASPHODELINE** (name modified from *Asphodelus*). *Liliaceæ*. Hardy herbaceous plants, distinguished from *Asphodelus* by the erect and leafy stems.

*Asphodelines* have long racemes of yellow or white fls. in June and July. All the older species were described under *Asphodelus*. In 1830, Reichenbach made the new genus *Asphodeline* for *A. lutea* and others. The only species advertised in Amer. is *A. lutea*, but all those described below are likely to be in cult. Monogr. by J. G. Baker in Journ. Linn. Soc. 15:273-278 (1877). There are some 145 species in the Medit. region and the Caucasus.

The culture of *Asphodeline lutea* is simple. Any soil will suit. Partial shade is allowable, but flowers are often better in the sun. Propagated readily by division, in spring or the fall.

A. *Sts. leafy up to the raceme*

B. *Fls. yellow.*

**lûtea**, Reichb. (*Asphodelus luteus*, Linn.). TRUE ASPHODEL of the ancients, or KING'S SPEAR. Height 2-4 ft.: roots thick, fleshy, stoloniferous: lvs. 3-12 in. long; margins rough: racemes 6-18 in. long, 3 in. wide: bracts large, membranaceous, persistent. Italy, Mauritania and Algeria to Tauria and Arabia. B.M. 773. L.B.C. 12:1102 as *A. tauricus*.—The best species. A double-fl. var. *flöre-plêno* has been advertised.

BB. *Fls. white.*

**taûrica**, Kunth. Height 1-2 ft.: roots slender: lvs. 3-9 in. long; margins membranaceous: racemes 6-12 in. long, 1½-2 in. wide: bracts 9-12 lines long, 1½-2 in. wide. Caucasus, Tauria, Syria, Asia Minor, Greece. G.C. III. 21:175.

AA. *Sts. leafy only a third or half the way to the raceme.*

B. *Fls. white: raceme dense.*

**globîfera**, J. Gay. Height 2-3 ft.: lvs. numerous, subulate 5-6 in. long, 1-1½ lines broad: racemes dense-fl. caps. globose. Cappadocia.

BB. *Fls. yellow: raceme lax.*

C. *Bracts large, 6-12 lines long, long-cuspidate.*

**tendîor**, Ledeb. Height 1 ft.: smaller than *A. lutea*, with finer lvs. and smaller, fewer and paler fls. Caucasus, Armenia, N. Persia. B.M. 2626.—Especially distinguished by the stalk being naked at the upper part, below the raceme of fls., and the bracts as short as or shorter than the peduncle.

CC. *Bracts small, 1½-3 lines long, short-cuspidate.*

**libûrnica**, Reichb. (*A. crêtica*, Vis., not Boiss.). Height 1-2 ft.: lvs. 3-4 in. long: racemes weak, 6-9 in. long, when expanded 2½-3 in. wide; stamens unequal. Greece, Crete, Dalmatia, Austria, Italy, not Asia Minor. L.B.C. 10:915 (as *A. crêtica*).

**brevicaûlis**, J. Gay (*A. crêtica*, Boiss., not Vis.). St. often flexuose, that of all the others here described being erect and strict. Asia Minor, Syria, Palestine, Egypt.

AAA. *Sts. leafy only at the base: fls. white: racemes dense.*

B. *Racemes usually simple.*

C. *Height 8 ft.: sts. having lf.-scales.*

**imperîâlis**, Siehe. Tallest species of the genus: fls. large, reddish white: lvs. numerous, forming a large rosette, and also clothing part of the st. Cappadocia. G.C. III. 22:397.

CC. *Height 1½-3 ft.: sts. not having lf.-scales.*

**damascêna**, Baker. Height 1½-2 ft.: bracts membranaceous, lanceolate, the lowest 9-12 lines long: racemes simple, rarely branched. Mt. Lebanon.

**Balansæ**, J. Gay. Height 2 ft.: bracts scarious, 6-9 lines long. Cilicia. Gt. 46, p. 521. G.C. III. 23:111.

BB. *Racemes much panicked.*

**isthmocârpa**, J. Gay. Height 2 ft. Cilicia. G.C. III. 23:117. WILHELM MILLER. N. TAYLOR.†

**ASPHÔDELUS** (Greek name of unknown origin). *Liliaceæ*. ASPHODEL. Hardy herbaceous stemless plants, with white, lily-like fls. in long racemes, fleshy fascicled roots, and firm, linear, radical, tufted lvs.: perianth funnel-shaped; segms. 6, oblong-ligulate, obtuse, equal, with a distinct nerve on the back, and always ascending.—Probably a half-dozen species in Medit. region and India.

The asphodel of the ancients, or king's spear, is *Asphodeline lutea*, which see. Homer mentions the asphodel meadows of the dead, where the shades of heroes congregated in Hades. The asphodel in Greek mythology was the peculiar flower of the dead. It has always been a common weed in Greece, and its pallid yellow flowers are associated with desert places and tombs. The word daffodil is a corruption of asphodel. The asphodel of the early English and French poets is *Narcissus Pseudo-Narcissus*. J. G. Baker, in his revision of the genus in Jour. Linn. Soc. 15:268-272 (1877), refers forty species of other botanists to *A. ramosus*, the dominant type, of which he makes three subspecies. These subspecies are here kept distinct, for horticultural purposes, as good species. They are the ones first described below. *A. ramosus* and *A. albus* are among the few current trade names in America.

Culture simple; see *Asphodeline*.

A. *Plant perennial: lvs. 3-angled.*

B. *Scape long.*

C. *Racemes simple or sparingly branched.*

**âlbûs**, Mill., not Willd. BRANCHING ASPHODEL. Bracts buff-colored when young: filaments deltoid at the base: caps. medium-sized, 5-6 lines long, subglobose or ellipsoid. S. Eu.

**cerasîferus**, J. Gay. Bracts pale yellow: filaments wedge-shaped at the base, but rapidly becoming awl-shaped: caps. large, 8-10 lines thick, flattish globular, umbilicate. W. Medit. region.

CC. *Racemes much branched or panicked.*

**comôdsus**, Ford. Radical lvs. sword-shaped, 1-1½ ft. long, acutish, sharply keeled on the back: panicle branched, the terminal racemose cluster 2-3 in. diam.; petals white, 5⁄8-¾ in. long. Himalayan region.

**tenuifôlius**, Cav. (*A. microcârpûs*, and *A. æstîvus*, Reichb.). Bracts pale yellow at first: filaments 4-angled at the base: caps. small, 3-4 lines long; obovoid-globose. Medit., Canary Isls.

BB. *Scape short, almost wanting.*

**acaûlis**, Desf. Lvs. 6-20, in a dense rosette, 3-4 in. long, minutely pubescent: fls. 6-20, in a crowded corymb; segms. of perianth 2-3 lines wide. Algiers. B.M. 7004.

AA. *Plant annual: lvs. cylindrical, hollow.*

**fistulôsus**, Linn. Height 16-20 in.: lvs. 12-30, in a dense rosette, 6-12 in. long, striate, awl-like, glabrous: segms. of perianth 1-2 lines wide, lined with pink: buds pink: fls. pinkish. France and Portugal to Syria, Arabia and Afghanistan. B.M. 984. L.B.C. 12:1124. —Needs protection under glass in winter. If removed early in autumn to a greenhouse, it may be induced to seed freely.

*A. crêticus* = *Asphodeline liburnica*. — *A. luteus* = *Asphodeline lutea*. — *A. Villarsii*, Verl., is a form of *A. ramosus*, from E. France, with long, dense racemes and dark brown bracts.

WILHELM MILLER. N. TAYLOR.†

XII. Asparagus, variety Colossal.

**ASPIDISTRA** (Greek, *a small, round shield*; referring, probably, to the shape of the stigma). *Liliaceæ*. A popular florists' plant, grown for its stiff, shining, beautiful foliage, which is sometimes striped.

Leaves all radical, many, long, gradually narrowed into petiole, the rhizome thick and sometimes creeping; fls. inconspicuous and borne close to the ground; perianth wide-campanulate, 8-lobed; stamens 8, attached on the tube, the filaments very short; ovary 4-celled: fr. a globose indehiscent 1-seeded berry.—Three or 4 species in Himalaya, China and Japan. The casual observer never suspects that *Aspidistra* is a liliaceous plant. The parts of the fl. in monocotyledons are typically in 3's. The genus *Aspidistra* is considered abnormal, as usually having its parts in 4's. This tetramerous state (which is here considered the normal one, and described below) is pictured in B.M. 2499, but the species was first described upon a trimerous state, and pictured in B.R. 628. In *A. lurida*, the trimerous state must be regarded as an exceptional reversion: in *A. typica*, B.M. 7484, the trimerous state is thought to be constant.

*Aspidistra* is invaluable to the florist in decorative work, owing to its ability to withstand rough usage, dust, heat, cold and drought. The foliage is very useful when cut for mixing with amaryllises when they are used as cut-flowers, lasting for weeks in good condition; for such purposes the *aspidistra* may be planted under greenhouse benches in waste places for the production of leaves alone. The variegated variety is often seen, but a poor soil must be used or the variegation will speedily disappear. To increase the plants, divide in early spring when repotting, shaking out the old soil from the roots and separating the leaves, putting several in a pot of a useful size, a 6-inch being large enough to hold a number of leaves and their roots. (E. O. Orpet.)

*lurida*, Ker-Gawl (*A. elatior*, Hort. *A. punctata*, Lindl.). Fig. 413. Lvs. 15–20 in. long, stiff, evergreen, oblong-lanceolate, sharp-pointed, radical; blade narrowed into a channeled petiole a third of its length: fls. lurid purple, on short 1-fl. scapes; perianth segms. 8; stamens 8; stigma broadly shield-shaped, like a small mushroom. China. B.R. 977. Var. *variegata*, Hort., has alternation of green and white stripes, no 2 lvs. being exactly alike.—In Fla., the *aspidistra* makes beautiful dense specimens in unheated plant-sheds. It thrives in sunshine when growing along the edges of ditches and flowing water.

*A. typica*, Baill. Rootstock creeping: lvs. elliptic-lanceolate, long-petioled, about 7-nerved: fls. greenish or whitish, speckled with red, purple inside, trimerous. China. L. H. B.†

**ASPIDIUM:** *Dryopteris* and *Polystichum*.

**ASPLENÉNDRIUM:** *Thamnopteris*.

**ASPLENIUM** (Greek, *not the spleen*; referring to supposed medicinal properties). *Polypodiaceæ*. A large, widely distributed genus of ferns, containing some 200 species. Some of them hardy, and many others grown in the greenhouse.

Aspleniums are distinguished by the free veins, and by the elongated sori covered by an indusium, which normally is attached to one side of a vein. The species here included under *Asplenium*, which have some of the sori curved across the subtending veinlets and certain differences in the internal structure of the st. are placed by many botanists in a separate genus, *Athyrium*; in the list below, Nos. 10, 25, 26, and 27 belong in this group.

Aspleniums enjoy an abundance of moisture at the roots, but they will turn brown in the winter months in

an excessively moist atmosphere. They should be kept in a very lightly shaded position. A good potting material consists of equal parts of rich soil and leaf-mold or peat. The following are some of the most useful commercial kinds: *A. Bélangeri*, height 2½ feet; *A. bulbiferum* (including *A. laxum*), which grows quickly into a handsome specimen about 20 inches high, and seems to stand the hot, dry American summers better than other species; *A. salicifolium*; and *A. viviparum*, which is dwarf, compact, with lace-like fronds, and easily propagated. For hanging-baskets, *A. flaccidum* is best. The foregoing species and others of like habit develop small plantlets on the surface and edge of pinnae. As soon as these are sufficiently strong, they may be detached, with a small piece of old pinnae, and pricked into shallow pans, the older part being placed below ground to hold the young plant firmly in position until roots have

413. *Aspidistra lurida* var. *variegata*.

formed. The best soil for this purpose is composed of equal parts of fresh garden soil, leaf-mold or fine peat, and sand. Plant very firmly, and place in a shady, moderately moist and close position, where in ten or fifteen days they will make roots. The foregoing ones do best in a temperature of 50° F. *A. cristatum* is easily grown from spores, and is very useful for fern-dishes. (Nichol N. Bruckner.)

A. Sori linear or oblong, straight, borne on the back of the lf. (Nos. 1–26.)

B. Lf. simple, with a serrate margin.

1. *serratum*, Linn. Lf. 1–3 ft. long, on a very short stalk, 2–4 in. wide, gradually narrowed below: sori 1 in. or more long. Fla. to Brazil.

2. *Nidus*, Linn. (*Thamnopteris Nidus*, Presl. A. and T. *Nidus-avis*, Hort.). BIRD'S-NEST FERN. Fig. 414. Much like the preceding in size and habit of growth, but with entire margined lvs. and with the veins partly united to form a net.

BB. Lf. lobed or pinnatifid.

3. *Hemionitis*, Linn. (*A. palmatum*, Lam.). Lf. 4-6 in. each way, hastate, with a triangular terminal lobe and 2 lateral ones, and a large, rounded sinus at the base: sori often over 1 in. in length. Spain, Canary Isls. S. 1:586.

4. *pinnatifidum*, Nutt. Lvs. clustered, from a short rootstock, 3-9 in. long, with mostly rounded lobes at the base and terminating in a slender point; texture thick, herbaceous; occasionally rooting at the tip. Pa. to Ala. S. 1:628.

5. *ebenoides*, R. R. Scott. Texture thin: lvs. 5-10 in. long, with a few irregular divisions near the base, and a long, slender, much-incised apical portion, occasionally rooting at the apex. A very rare native fern.—One of the very few definitely proved fern hybrids, its hybrid name being *A. platyneuron* × *Camplosorus rhizophyllus*.

414. *Asplenium Nidus*. (× $\frac{1}{10}$ )

6. *alatum*, HBK. Lvs. 1½-2 ft. long, the stalks 4-6 in. long, winged above, the blades 1-1½ ft. long, 3-4 in. broad, deeply pinnatifid, the rachis winged throughout, the lobes 1-1¼ in. long, ½-¾ in. broad, herbaceous.—W. Indies and S. Amer.

BBB. Lf. once pinnate.

c. Pinnæ less than ¾ in. long, blunt.

d. Rachises greenish.

7. *viride*, Hudson. Lvs. 3-8 in. long, scarcely more than ½ in. wide, with numerous rather distant lfts., which are ovate and deeply crenate: sori abundant, oblique. A subalpine species of N. Eu. and N. Amer. S. 1:661.

DD. Rachises purplish or blackish.

8. *Trichomanes*, Linn. Lvs. densely clustered, 3-8 in. long, ½ in. wide, with densely crowded oval lfts., which are slightly crenate on the upper side and suddenly narrowed at the base. Northern hemisphere generally. A.G. 13:653. S. 1:653. Gn. 59:318 (as *A. incisum*).

9. *resiliens*, Kunze (*A. parvulum*, Mart. & Galeotti). Lf. 5-9 in. long, with 20-30 pairs of mostly opposite lfts.,

which are ¼-¾ in. long, rounded at the outer margin and squarely truncate at the base. Southern states and Mex.

cc. Pinnæ ¾-1 in. long, with a strong auricle at the upper side of the base or deeply incised on the upper margin.

10. *platyneuron*, Oakes (*A. ebenum*, Ait.). Lvs. 6-15 in. long, with 30-35 pairs of lfts. which have an enlarged auricle at the upper side at the base, the lower lfts. reduced to mere triangular auricles: sori, when mature, covering the entire surface. Canada to S. Amer. A.G. 13:654. S. 1:535.

11. *formosum*, Willd. Lvs. 12-16 in. long, with numerous alternate pinnæ which are mostly deflexed, with the upper margin deeply incised and the lower margin toothed: sori 3-5 to each lft. Trop. Amer. S. 1:576.

12. *tenerum*, Forst. (*A. Veitchianum*, Hort.). Lvs. 1-1¼ ft. long, the stalks 4-6 in. long, grayish, the blades 8-15 in. long, 3-4 in. broad, 1-pinnate with 10-20 pairs of stalked pinnæ, the pinnæ 1-1½ in. long, ¼-¾ in. broad, rounded, toothed, inequilateral, usually auricled. Asia, Malaya.

13. *Colensoi*, Col. Stalks 3-4 in. long, with small scales: lf.-blades 4-5 in. long, 2 in. broad; pinnæ numerous, spreading, the lower pinnatifid auricled, on stalks ¼-½ in. long. New Zeal.

ccc. Pinnæ 3-6 in. long, linear or lanceolate.

14. *angustifolium*, Michx. Lvs. 18-24 in. long on stout stalks, 4-6 in. wide, with 20-30 pairs of nearly sessile pinnæ, which are truncate at the base and extend to a tapering point; fertile pinnæ narrower and more distant. Moist woods northward. S. 1:496.

15. *salicifolium*, Linn. Lvs. 12-18 in. long, with about 20 distinctly stalked horizontal pinnæ, which are wedge-shaped at the base, and curve upward to a long point: sori strongly oblique to the midrib, wide apart, not reaching either margin or midrib. W. Indies to Brazil.

16. *caudatum*, Forst. Stalks 4-6 in. long, densely clothed with fine fibrillose scales: blades 12-18 in. long, 4-8 in. broad, with 20-30 pairs of pinnæ, the pinnæ 3-4 in. long, ½-1 in. broad, acuminate, deeply toothed, auriculate above. Polynesia, Malaya.

17. *lucidum*, Forst. Stalks 3-6 in. long, grayish, densely clothed with large gray scales, the blades 1-2 ft. long, 4-8 in. broad, oblong, or ovate-deltoid, with a terminal pinna and 15-20 pairs of lateral pinnæ; pinnæ 4-6 in. long, 1-1½ in. broad, acuminate, toothed. New Zeal.

BBBB. Lf. 2-4 pinnate.

c. Ultimate divisions linear or cuneate; venation somewhat fan-shaped; texture thick.

18. *Báptistii*, Moore. Lf. bipinnate, with broadly ovate pinnæ 5 in. or more long, each with about 4 stipitate linear toothed pinnules; sori nearly parallel with the midvein and close to it; rachises scaly, with purplish lined scales. South Sea Isls.

19. *affine*, Swartz. Lf. 9-18 in. long, with numerous pinnæ on either side, the lower ovate deltoid, the upper lanceolate; pinnules incised: sori linear. Mauritius and Ceylon to E. Indies.

20. *Adiantum-nigrum*, Linn. Stalks brownish, lvs. 3-pinnatifid from winged rachises, triangular, 5-9 in. long; ultimate divisions ovate, sharply incised and serrate on both sides. Old World generally. S. 1:486.

21. *cuneatum*, Lam. Lvs. 12-16 in. long, 4-6 in. wide, tripinnate below, the ultimate divisions broadly obtuse above and strongly cuneate below: sori linear, usually long for the size of the segms. Tropical regions generally.

22. *frágans*, Swartz (*A. fœniculaceum*, Kunth). Lvs. 2-3-pinnate; ultimate segms. lanceolate, sharp-serrate above; veins simple or the lowest forked: sori

oblong, extending from midrib to near base of the lobes: petiole brownish, rachis flattened. W. Indies. S. 1:577.

cc. *Ultimate divisions rhombic, sharply spinulose: texture herbaceous.*

23. **fontanum**, Bernh. Growing in dense clusters: lvs. 3-6 in. long, 1 in. or more wide, 2-pinnate; segms. with 2-5 spinulose teeth which are widely divergent: sori at maturity covering nearly the entire surface of the segms. England and Spain to the Himalayas. S. 1:574.

ccc. *Ultimate divisions longer, not spinulose: texture membranous or herbaceous.*

24. **bulbiferum**, Forst. (*A. laxum*, Hort.). Lvs. 1-1½ ft. long, 6-8 in. wide, 3-pinnatifid; pinnæ tapering to a slender toothed point: often bearing bulbs from which new plants originate while still attached to the lf. Afr. and Australasia. S. 1:508. Gn. 72:156.

25. **myriophyllum**, Presl. (*A. rhizophyllum*, Kunze). Fig. 415. Growing in extensive tufts, with grayish brown stalks and rachises: lvs. 6-15 in. long, 3-pinnate or 4-pinnatifid, the ultimate segms. frequently deeply 2-lobed with a single sorus to each division. Fla. to S. Amer.

26. **cristatum**, Lam. (*A. cicutarium*, Swartz). Lvs. 3-pinnatifid with a winged rachis, 8-18 in. long; pinnules ovate, with 5-7 narrow divisions, each bearing a single sorus; texture thin, membranous. Trop. Amer., rare in Fla.

AA. *Sori linear, marginal or submarginal, on narrow, linear, ultimate divisions of the lf. (Darea.)*

B. *Lvs. bipinnatifid, less than a foot long.*

27. **oceanicum**, C. Chr. (*A. obtusilobum*, Hook., not Desv.). Lvs. 4-7 in. long, 2 in. wide or less, with about 10 pinnæ, which are made up of 5-7 narrow segms. bearing occasional sori in the outer margin of the segms. New Hebrides and Fiji Isls. S. 1:625.

BB. *Lvs. 2-pinnate or 3-pinnatifid, over a foot long.*

C. *Pinnæ short, with close segms.*

28. **rutæfolium**, Kunze. Lvs. 13-15 in. long, with 12-20 pinnæ on each side, each with 7-11 narrow segms., 2 or 3 of the lower ones 2-fid. or rarely 3-fid. S. Afr., India and Japan.

29. **Belangeri**, Kunze. Fig. 416. Lvs. 15-18 in. long, 3 in. wide, with numerous horizontal pinnæ on each side, cut into about 12 slender linear segms. on either side, which are set nearly at right angles to the rachis; the lower basal segms. often forked. Each segm. has a single sorus, and 1 vein. This species is thought by some fern students to be merely a divided variety of *A. tenerum*, Forst. (No. 12). In general the two species are much alike. E. Indies.

30. **dimorphum**, Kunze. Stalks 6-12 in. long, naked: blades 2-3 ft. long, 12-15 in. broad, ovate-deltoid, 2-3 pinnate; sterile lvs. 2-pinnate, segms. ovate 1 in. long, ½ in. broad, bluntly toothed; fertile lvs. 3-pinnate, segms. linear, each with a single sorus. Norfolk Isl.

cc. *Pinnæ longer, with scattered narrowly linear segms.*

31. **viviparum**, Presl. Lvs. 15-24 in. long, 6-8 in. wide, on rather short stalks with pinnatifid pinnules and ultimate segms., which are narrowly linear and often forked: plant often bulb-bearing, like *A. bulbiferum*. Mauritius and Bourbon. Cult. under various names. S. 1:662. *A. nobilis*, Hort., is a more vigorous variety, originally from New Guinea.

AAA. *Sori more or less curved, sometimes horseshoe-shaped: lvs. ample, 2-4-pinnatifid.*

32. **Filix-fœmina**, Bernh. Lvs. 1½-3 ft., broadly ovate-oblong, bipinnate; pinnæ 4-8 in. long, lanceolate, with numerous more or less pinnately incised or serrate segms. Eu. and N. Amer.—Very variable, especially in cult. Schneider describes 56 varieties.

33. **acrostichoides**, Swartz (*A. thelypteroides*, Michx.). Lvs. 1-2 ft. long, on long, straw-colored stalks, 6-12 in. wide, 2-pinnatifid, with linear-lanceolate pinnæ; segms. crowded, oblong, minutely toothed: sori 10-12 to each segm. Rich soil in the E. U. S. S. 1:651.

34. **spinulosum**, Baker. Lvs. 9-12 in. each way, deltoid, 3-4-pinnatifid, with 9-12 pinnæ on either side, the lowest much the largest; segms. short and sharply toothed. China and Japan.

Supplementary list of less common trade names: *A. aculeatum*, Hort. Hab. (?).—*A. arboreum*. See Diplazium.—*A. bifidum* = *A. lineatum*.—*A. decorum*, a sport from *A. bulbiferum*.—*A. decussatum*. See Callipteris.—*A. ellipticum*, Hort., a trade name.—*A. flaccidum*, Forst. Coolhouse basket fern from Austral., Tasmania and New Zeal. Lvs. 2-3 ft. long, 4-8 in. broad; stipes stout, flexible, greenish, naked; pinnæ numerous, close or distant, lanceolate, leathery, 4-8 in. long, ½-¾ in. broad. Very variable.—*A. Goringianum* var. *pictum*, Mett (*Athyrium Goringianum* var. *pictum*, Hort.). Distinguished from all other members of the genus by the bright color of its entirely deciduous lvs., which are 10-15 in. long, spear-shaped, and pendulous. Possibly the only hardy variegated fern. It, however, needs glass protection for best results. Stalks purple or claret-colored: lvs. green with a central band of gray; lfts. divided into sharply toothed pinnules on which the oblong or kidney-shaped sori are arranged in 2 rows parallel to the midvein. Japan.—*A. laceratum*, Desv. Allied to *A. Nidus* and possibly a variety of that species. Lvs. narrower, cut into irregular lobes, each lobe having black stripe about 3 in. long. Brazil.—*A. lanceum*. See Diplazium.—*A. Lauréntii*, Christ. var. *denticulatum*. Allied to *A. macrophyllum* but smaller. Congo.—*A. lineatum*, Swartz. Warmhouse species from Mauritius and Bourbon, is very variable, running into forms with lfts. again pinnate, which have either small, linear pinnules or these again twice cut: lvs. 1-2 ft. long, 4-6 in. wide; stalks erect, 6-9 in. long, more or less scaly.—*A. longissimum*, Blume. The best of all the genus for large baskets. Lvs. 2-3 ft. long, 4-6 in. broad; stalks blackish, 3-12 in.

416. *Asplenium Belangeri*. (×¾)

long: lfts. sessile, auricled. E. Indies. S. 1:602.—*A. macrophyllum*, Swartz. Coolhouse species from Polynesia, Malaya, China, and Himalayas. Lvs. 6-18 in. long, 6-12 in. wide; stalks brownish: lfts. 6-12 pairs, stalked, 3-6 in. long, 1-3 in. wide, sharp-pointed, serrate.—*A. Shepherdii*, Spreng. See Diplazium.

L. M. UNDERWOOD.  
R. C. BENEDICT.†

ASPRÉLLA: *Hystrix*.

**ASTÈLIA** (name alluding to epiphytic character of some species). *Liliaceæ*. Greenhouse plants with racemes or panicles of small flowers.

Astelias are perennial herbs of about a dozen species in New Zeal., Austral. and the Pacific Isls., with lvs. all radical or crowded at the base of the st., belonging to the Dracæna tribe: fls. small and diœcious; perianth

6-parted, persistent, the parts spreading or reflexed; stamens 6, attached to base of corolla-parts; staminodia present in pistillate fls., the ovary sessile, 1-3-celled: fr. an indehiscent somewhat fleshy and globose berry. In New Zeal., the astelias form a prominent part of the vegetation. The species are confused. Two or 3 New Zeal. species have been sparingly intro. to cult. abroad, as: *A. Cunninghamii*, Hook. f., with 1-celled fr.: fls. numerous and small, greenish yellow or reddish yellow or maroon: a densely tufted species, epiphytic or terrestrial, with lvs. 2-5 ft. long and scape 1-3 ft. B.M. 5175. *A. Banksii*, Cunn., with 3-celled fr.: fls. larger (about  $\frac{1}{4}$  in. long), many, greenish: densely tufted, large, the lvs. 2-6 ft. *A. Solandri*, Cunn., with 3-celled fr.: fls. very numerous and lemon-yellow,  $\frac{1}{2}$  in. long: densely tufted, often making large clumps on trees and rocks, the lvs. 2-5 ft. B.M. 5503. L. H. B.

**ÁSTER** (a star). Including *Diplopappus*. *Compósitæ*. **ASTER. STARWORT. MICHAELMAS DAISY.** A large temperate-zone genus of attractive but botanically-confused, mostly perennial leafy herbs, particularly abundant in North America; very useful for border planting.

The genus is characterized by numerous flattish rays (white, blue, red, or purple), slender subulate or lanceolate style appendages, compressed several-nerved achenes, and an involucre with unequal bracts in few or several rows, the pappus simple, soft, and abundant (Fig. 417); leafy stemmed, mostly blooming in the autumn: lvs. always alternate. It differs from *Erigeron* in having 2 to several rows of involucre bracts; in *Erigeron* there is only 1 series of bracts.

Some of the species are annual, but those in cult. are perennial (or rarely biennial). Calimeris and *Linosyris*, which have yellow fls., a color unknown in aster, are kept distinct in this book.

In North America, where the asters are such abundant plants in the autumn flora, the species are not much known as cultivated plants, most of the specimens seen in gardens being the wild species transplanted. In Europe, however, there are numbers of named garden kinds, some of them derived from American species that have been long cultivated there. *A. novi-belgii* has been particularly productive of garden forms. Many of the garden forms are undoubtedly confused hybrids. The Michaelmas daisies are mostly from this species and perhaps also from *A. novæ-angliæ*. Many of the Latin-form garden names are very difficult to place.

The native asters are amongst the very best plants for borders and roadsides. They should be better known. *A. acuminatus* grows well in shade in ordinary soil, not necessarily moist; increases in vigor under cultivation. *A. cordifolius* prefers open or partial shade; improves much under cultivation with good soil. *A. corymbosus* prefers at least partial shade, and will grow even in very deep shade; seeds very freely; does well on dry ledges and in small crevices in rock; very tenacious of life. *A. dumosus* prefers full sunlight and dry situation. *A. ericoides* wants full sunlight and dry situation; will grow in very poor or shallow soil, but does best where roots can penetrate deep. *A. laevis* grows in either full sunlight or partial shade and good soil. *A. novæ-angliæ* will not endure much shade; prefers moist soil, but grows well in ordinary garden situations. Fall-sown seedlings of *A. novæ-angliæ* var. *roseus* come practically true to varietal name, though varying in shade of color, and these seedlings bloom later than

older plants and at a height of 18 inches, making the plant of value as a late bedding plant treated as an annual. *A. novi-belgii* prefers moist soil; will not endure heavy shade. *A. paniculatus* prefers moist soil, but will do well in rather dry situations; will endure more shade than either of the two above species. *A. patens* wants open or half-shaded places, and good soil; one of the weaker species, often proving short-lived. *A. puniceus* will not endure shade; prefers moist

418. *Aster macrophyllus*. ( $\times \frac{1}{2}$ )

places, but will grow in good soil not over-moist; in dry situations it loses its vigor; spreads rapidly in favored locations. *A. spectabilis* prefers open or partly shaded places; one of the weaker species in wild state; rather short-lived. *A. undulatus* wants open or half shade; late-flowering, handsome plant, forming large clumps when allowed to develop. (F. W. Barclay.)

The garden or modified asters undoubtedly deserve more attention in American collections. The beautiful low-growing, vernal alpine asters are little known at present, but are valuable for rock-garden and for bordering purposes. The earliest asters to flower are the Alpine varieties. These are well adapted for floral mass effects, and transplant well, even in an advanced state. There are many garden varieties of asters, among which are Schoene von Ronsdorf, Ultramarin, Beauty of Colwall, Beauté Parfaite, Rosalind and Boule de Neige. Alpine asters can be easily raised from seed sown in spring. Seedlings do not flower until the second year. In the garden they require a light rich soil, open exposure and moderate amount of moisture. Plants retain their foliage over winter and for this reason need a more careful covering than the tall-growing classes require. Garden varieties of the latter, as a rule do better in low and rather moist locations. Here a minimum of care is sufficient. To bring out their full beauty, however, it is necessary to plant them in well-prepared richly manured ground and properly to cultivate, stake and irrigate them. Stock of named varieties must be purchased as plants. Propagation can be effected by division of old clumps, or, if larger quantities are

417. Disk floret of Aster. ( $\times 3$ )

a, pappus; b, corolla; c, stamens; d, styles.

desired, by cuttings. If distinctness of variety and color is no object, seeding may be employed; sow early in spring, thinly in rows; transplant seedlings in August or early in September and await their coming into flower the following season. (R. Rothe.)

A. Old World asters, some of them old garden plants, and somewhat modified by cult. Nos. 1-12.

B. Sts. simple and scape-like, bearing a single fl., sometimes branched in A. Thomsonii.

c. Rays purplish or violet.

1. *alpinus*, Linn. Lvs. entire and spatulate, forming a cluster on the ground, those on the st. small and linear: st. 3-10 in., bearing a large violet-rayed, handsome head. B.M. 199. Gn. 76, p. 122.—In its wild state, the plant also occurs in the Rocky Mts. Valuable alpine or rockwork plant, with fls. varying to pink and white. Var. *speciosus*, Hort., is taller and stronger, with heads 3-4 in. across. Var. *superbus*, Hort. (Gn. 54:328. G. 32:591), is a large and showy form. Var. *albus* is a beautiful pure white-fl. form of the type. G.M. 50:617.

2. *Thomsonii*, Clarke. An erect, sometimes laxly branched herb, with slender, flexuous, hairy branches: lvs. 2-4 in. long, almost clasping at the base: fls. solitary, 1½-2½ in. wide, the rays reddish purple, about 20-30 in each head. Himalaya region. Gn.W. 23:27. Gn. 42, p. 295.—To be treated as an alpine near N. Y. Perhaps better referred to *Calimeris*.

cc. Rays predominantly blue or lilac.

d. Plants low, not over 1 ft. in height.

3. *himalaicus*, C. B. Clarke (A. *himalayensis*, Hort.). Similar to A. *alpinus*, but dwarfer: rays lilac-blue, slightly recurved at the tip: sts. 4-12 in., slightly villous: lvs. oblong or elliptic, nearly entire. Himalayas, 13,000-15,000 ft.—Little known in Amer.

4. *subcæruleus*, S. Moore. Erect herb from a tufted mat of foliage with sessile, nearly oblong lvs., all a little hairy: lvs. entire or sometimes slightly denticulate: fls. large, solitary on long stalks, at least 2 in. wide, the rays a beautiful pale blue, the disk yellow; involueral lvs. broadly oblong, ciliate. N. W. India. June. G. 32:449.

G.C. III. 38:23. G.M. 48:411. Gn. 68, p. 11.—Needs protection N. June.

5. *pyrenæus*, DC. St. erect, simple, 10-18 in. high: lvs. sessile, roughly pubescent, oblong-lanceolate and prominently 3-nerved: fls. solitary or 2 or 3 together, at least 2½ in. wide, the numerous rays lilac, the disk fls. yellow. S. Eu. Aug., Sept.

DD. Plants 2-3 ft. high.

6. *diplostephioides*, Benth. Two to 3 ft., soft-pubescent or hairy, the st. simple and solitary: lvs. obovate or oblanceolate, entire but ciliate: solitary head large, inclined, 2-3 in. across, blue or pale purple, very showy. Himalayas. B.M. 6718. J.H. III. 33:262. G.C. III. 48:56. G.M. 35:445.—In the American trade has been misspelled A. *Deptostaphides*. Var. *Falconeri*, Clarke (A. *Falconeri*, Hort.), from Cashmir, has very large sky-blue heads.

BB. Sts. usually branched and several- to many-fl.

7. *Amellus*, Linn. St. simple or nearly so, few-fl. or sometimes only 1-fl.: lvs. oblong-lanceolate, obtuse, somewhat serrate, more or less 3-nerved, roughish, pubescent: involucre scales oblong, obtuse or nearly so, spreading, in 4-5 rows; heads large, purple. Eu. and

419. *Aster cordifolius*. A handsome blue-flowered native aster. (X½)

420. *Aster novæ-angliæ*. One of the best and most showy of native asters. (X¼)

Asia. Gn. 27, p. 202; 35:172.—Variable, and several well-marked garden forms.

8. Var. *bessarabicus*, DC. (A. *bessarabicus*, Bernh.). Lvs. oblong and attenuated at base: plant taller and larger-fl., deep purple. G. 21, p. 167. Gn. 35, p. 173; 75, p. 511.—Showy and desirable.

9. *sibiricus*, Linn. A foot or sometimes nearly 2 ft. high, somewhat pubescent, each branch terminating in a single head: lvs. oblong-spatulate to broad-lanceolate, serrate, almost clasping the st.: heads violet or lilac.

Arctic Eu. and Amer., and Rocky Mts.—Excellent rockwork plant.

10. *àcris*, Linn. About 2-3 ft., slender-branched: lvs. linear, or lance-linear: heads large and blue, with long, distinct, handsome rays. S. Eu. Gn. 37:240. G.M. 34:615.—Excellent showy garden plants. A dwarf form is *A. canus*. Var. *nānus* is a very dwarf form, not exceeding 15 in.

11. *trinerviū*, Roxbg. About 3 ft., stout, corymbose at summit: lvs. lance-ovate, 1-4 in. long, usually rough on both sides and strongly toothed: heads large, blue or purple (a pale variety) with narrow, spreading rays. Himalayas. R.H. 1892:396.—Hardy, handsome, variable.

12. *tataricus*, Linn. f. St. erect and striate, hispid, corymbose at the summit, often 7 ft. high: lvs. large (the radical 2 ft. long), lanceolate or oval lanceolate, attenuate at base, entire: involucre scales purplish at

421. *Aster Herveyi*.  
( $\times \frac{1}{2}$ )

tip; heads blue or purple, late. Siberia. G.F. 4:197.—Excellent for the hardy border, particularly for its very late blooming. Var. *Petersianus*, Hort., has narrower lvs. and pale blue rays and yellow disk. China.

AA. *Native Asters*. These plants are one of the charms of the American autumn, and are amongst the best of all hardy border plants. They usually improve greatly in habit when transferred to cultivated grounds. Any of these wild asters are likely to come into cultivation at any time. The number of kinds is large. The student will find them all described in Gray's *Synoptical Flora of North America*, 1, pt. 2. Those of the northeastern states and adjacent Canada will be found in Britton and Brown's *Illustrated Flora of the United States* and Gray's *Manual*. Those of the South are described in Small's *Flora of the Southeastern States*, and those of the Rocky Mountains in Nelson's *Manual of Rocky Mountain Botany*. The following comprises those known to be in cultivation. Of these, *A. novæ-angliæ* is the best known in domestication. The species are much confused.

B. *Basal and lower lvs. cordate and slender petioled*.  
c. *Plant glandular: rays violet*.

13. *macrophyllus*, Linn. Fig. 418. Perennial about  $2\frac{1}{2}$  ft. tall with reddish angular st.: lvs. cordate and petioled below, on the upper part of st. sessile and acute: rays about 16, violet-lavender, the involucre bracts prominently green-tipped. E. N. Amer. G.F. 4: 89 (adapted in Fig. 418).—Suitable for dry shady places.

cc. *Plants not glandular: rays blue or purple*.

14. *Shörtii*, Hook. Perennial, 3-4 ft., with a rough, usually slender paniculately branched st.: lvs. thick, usually quite smooth, the lower cordate, the upper lanceolate and quite entire and those of the small branches bract-like: heads very numerous, the 10-15 violet-blue rays showy and linear. S. E. U. S. G.F. 4:473. G.C. III. 32:269.—Cult. easy, even in dry rocky places.

15. *cordifolius*, Linn. Fig. 419. Perennial, much-branched herb, 3-4½ ft., with a smooth st. and thin, rough, usually hairy lvs., the lower cordate, the upper ovate or lanceolate: heads very numerous, not over ½ in. diam., the pale blue rays usually 10-20 in number. Cent. N. Amer. Gn.M. 3:211.—Can be grown almost anywhere. There are many varieties, the best being var. *polycéphalus* with more heads than the type. Gn. 40, p. 337.—In cult. it has varied much and is prized abroad. *A. elegans* is probably a form of it. Var. *magnificus* is large with many small fls.

BB. *No cordate and petioled lvs.: those of the st. with clasping bases*.

c. *St. rough or hirsute, pubescent*.

16. *novæ-angliæ*, Linn. NEW ENGLAND ASTER. Fig. 420. A stout-st. corymbosely branched perennial, 3-5 ft.: lvs. oblong-lanceolate, clasping the st., hairy, 2½-4 in. long: fls. numerous, showy, the 40-50 violet-purple rays about ½-¾ in. long. E. N. Amer. A.F. 9:283.—The best and most widely known native aster suitable for open places but partial to moisture. Var. *roseus*, Hort., an excellent rose-colored form, is offered by some dealers. Many cult. forms in European collections.

cc. *St. quite smooth*.

17. *lævis*, Linn. (*A. decurrens*, Hort.). Perennial, with stout often glaucous st., 2-3 ft.: lvs. thick, sharply toothed, often rough-margined, the upper strongly st.-clasping: heads numerous, about 1 in. wide, the 15-30 blue or violet rays acutish. N. E. N. Amer.—There are several varieties, but apparently not known to the trade.

18. *novi-bélgii*, Linn. NEW YORK ASTER. Widely variable, slender-st. perennial, 2-3 ft.: lvs. lanceolate, or oblong-lanceolate, entire, smooth, 2½-5 in. long: heads many, in a corymbose-paniculate infl., the 15-25 rays a rich violet. Atlantic coast from Maine to Ga.—Suitable for moist places. Many garden varieties and hybrids are known, but they are mostly confined to the European trade. *A. éminens* and *A. cæspitosus* probably belong here.

BBB. *Lvs. neither cordate nor st.-clasping*.

19. *Herveyi*, Gray. Fig. 421. A rough-st. perennial, 2-3 ft., with firm lvs. that are rough above, hairy on the veins beneath, 2½-5 in. long, and toothed: heads numerous, about 2 in. broad, with 15-25 violet rays, very showy. New England. G.F. 2:473 (adapted in Fig. 421). Good for dry sandy soil.

20. *ericoides*, Linn. WHITE HEATH ASTER. FROST-WEED ASTER. A smooth-st. perennial with paniculately, much-branched facies, 2-3 ft.: lvs. slender, those of the st. narrowly linear and acute, not over 2½ in. long, usually shorter: fls. very numerous, the heads not over ¾ in. wide, and composed of 15-25 white rays.

Not very showy. E. N. Amer. J.H. III. 49:465. Gn. 32, p. 318.—Useful for naturalizing in open dry situations.

Besides these, many other native species are from time to time found in the catalogues of dealers in native plants. The most common are:

*A. acuminatus*, Michx.; *A. amethystinus*, Nutt. (G.F. 5:378); *A. Andersonii*, Gray; *A. Bigelovii*, Gray (B.M. 6430); *A. canescens*, Pursh; *A. carnosus*, Gray; *A. carolinianus*, Walt.; *A. Chamissonis*, Gray; *A. Chapmanii*, Torr. & Gray; *A. commutatus*, Gray; *A. concolor*, Linn. (Mn. 10:161); *A. conspicuus*, Lindl.; *A. corymbosus*, Ait.; *A. Cusickii*, Gray; *A. diffusus*, Ait., and var. *horizontalis*; *A. Douglasii*, Lindl.; *A. Drummondii*, Lindl.; *A. dumosus*, Linn.; *A. falcatus*, Lindl.; *A. Fendleri*, Gray; *A. foliaceus*, Lindl. N. TAYLOR.†

#### ASTER, CHINA

(*Callistephus hortensis*). One of the most popular of all garden annuals, being particularly valuable for its fall blooming.

The evolution of the China aster suggests that of the chrysanthemum at almost every point, and it is, therefore, a history of remarkable variations. The plant is native to China. It was introduced into Europe about 1731 by R. P. d'Incarville, a Jesuit missionary in China, for whom the genus *Incarvillea* of the Bignonia family was named. At that time it was a single flower; that is, the rays or ligulate florets were of only two to four rows. These rays were blue, violet or white. The center of the flower (or head) was comprised of very numerous tubular, yellowish florets. Philip Miller, the famous gardener-botanist of Chelsea, England, received seeds of the single white and red asters in 1731, evidently from France; and he received the single blue in 1736. In 1752 he secured seeds of the double red and blue, and in 1753 of the double white. At that time there appears to have been no dwarf forms, for Miller says that the plants grew 18 inches or 2 feet high. Martyn, in 1807, says that, in addition to these varieties mentioned by Miller, there had then appeared a "variegated blue and white" variety. The species was well known to American gardeners at the opening of the last century. In 1806 M' Mahon, of Philadelphia, mentioned the "China aster (in sorts)" as one of the desirable garden annuals.

422. *Aster Lindleyanus*. (× 1/2)

423. *Aster puniceus*. (× 1/2)

Bridgeman, a New York seedsman, offered the China and German asters in 1837 "in numerous and splendid varieties," specifying varieties "alba, rubra, cerulea striata purpurea, etc." In 1845, Eley said that "China and German asters" "are very numerous" in New England. This name German aster records the fact that the first great advances in the garden evolution of the plant were made in Germany, and the seed then used came largely from that country. The first marked departure from the type appears to have been the prolongation or great development of the central florets of the head, and the production of the "quilled" flower. This type of aster was very popular fifty and sixty years ago. Breck, in the first edition of his "Flower Garden," 1851, speaks of the great improvement of the aster "within a few years" "by the German florists, and others," and adds that "the full-quilled varieties are the most highly esteemed, having a hemispherical shape, either a pure white, clear blue, purple, rose, or deep red; or beautifully mottled, striped, or edged with those colors, or having a red or blue center." About sixty years ago the habit of the plant had begun to vary considerably, and the progenitors of our modern dwarf races began to attract attention. The quilled, high-centered flower of a generation or more ago is too stiff to satisfy the tastes of these later days, and the many flat-rayed, loose and fluffy races are now most in demand, and their popularity is usually greater the nearer they approach the form of the uncombed chrysanthemums.

The China aster has long since varied into a wide range of colors of the cyanic series—shades of blue, red, pink and purple. The modern evolution of the plant is in the direction of habit and form of flower. There are various well-marked races or types, each of which has its full and independent range of colors. The Comet type (with very flat rays), now one of the most deserving of the China asters, illustrates these statements admirably. This Comet form—the loose, open flower with long, strap-like rays—appeared on the market about 1886 or 1887, with a flower of a dull white overlaid with pink. The pink tended to fade out after the flower opened, leaving the color an unwashed white.

The rose-colored Comet next appeared, and the blue was introduced in 1890. The first clear white was introduced in America in 1892, coming from Vilmorin, of Paris. The Branching types marked a departure. The introduction of the "New White Branching" by James Vick's Sons, in 1893, gave the main impetus to the commercial development of the aster in America.

It is probable that more than one-half of all the asters now grown in

the United States are of the various Branching varieties. The named garden forms of China aster are several hundred. As early as 1895, American seedsmen offered 250 varieties. Some of the forms are shown in Figs. 424-427. For botanical account of the China aster, see *Callistephus*.

It is impossible to construct a satisfactory classification of the China asters. It is no longer practicable to classify the varieties by color. Neither is it feasible to classify them upon habit or stature of plant, for several of the best marked types run into both tall and dwarf forms. Vilmorin, however, divides the varieties into two main groups, the pyramidal growers, and the non-pyramidal growers. The most elaborate classification is that proposed by Barron, from a study of extensive tests made at Chiswick, England. Barron has 17 sections, but they are not coördinate, and they are really little more than an enumeration of the various types or classes. After considerable study of the varieties in the field and herbarium, the following scheme seems to be serviceable:

425. China aster, the Branching type.

- A. Flat-rayed asters, in which all, or at least more than 5 or 6 rows of rays, are more or less prominently flat and the florets open.
- B. Incurved or ball-shaped.
- BB. Spreading or reflexed.
- AA. Tubular or quilled asters, in which all, or all but the 2 or 3 outer rows of florets, have prominently tubular corollas.
- B. Inner florets short, outer ones longer and flat. Represented by the German Quilled.
- BB. All the florets elongated and quilled.

A grower's classification (Arnold) would be approximately as follows:

*Upright*.—All the branches erect; plants compact: e. g., Victoria, Truffaut, Giant Comet.

*Semi-upright*.—Branches few; strong; ascending from base: e. g., "non-lateral" type of Branching.

*Branching*.—Strong pyramidal habit. Original type much branched.

*Spreading*.—More open and spreading form than Branching: e. g., Queen of the Market, Early Wonder and Early Hohenzollern.

For growing in borders, one of the best types is the Comet (Fig. 424), in various colors. Other excellent races are the Branching (Vick's Branching is shown in Fig. 425); Truffaut, known also as Perfection and Peony-flowered; Chrysanthemum-flowered; Washington; Victoria, Mignon, and Queen of the Market. The last is commended for earliness and graceful, open habit, and it is one of the best for cut-flowers. Many other types are valuable for special purposes. The Crown or Cocardeau is odd and attractive. Amongst the quilled asters, the various strains of German Quilled (Fig. 426), Victoria Needle (Fig. 427), and Lilliput are excellent. The very dwarf tufted asters are well represented in Dwarf Bouquet or Dwarf German, and Shakespeare. All these are easily grown in any good garden soil. For early bloom, seeds may be started under glass; but good fall bloom may be had, even in the North, by sowing seeds in the open as late as the 1st of June. Asters make very showy bedding plants when grown in large masses, and are also valuable for filling up vacancies in the mixed herbaceous border, where they ought to be planted in clumps, the dwarfier kinds put in front and the taller behind. The colors of asters are not so strong or heavy as to introduce violent contrasts, and for this reason, as well as because of their simple requirements, they are useful and popular.

L. H. B.

424. China aster, the Comet type. ( $\times \frac{1}{2}$ )

The China aster is now grown largely for cut-flowers, rather than merely for garden decoration. Commercially, it is the most important of the cut-flowers that are grown out-of-doors. In the garden of the amateur, it divides honors with the sweet pea. The commercial value of aster seed sold by American seedsmen exceeds that of any other flower. In addition to the large amount of aster seed grown in southern California, New York now produces annually twenty hundredweight of seed, mostly in varieties used by the commercial florist. The principal reasons for the popularity of the aster with florists, aside from its range of useful colors, are its excellent keeping qualities as a cut-flower, its ability to stand rough handling in shipping, and the ease with which it may be grown.

The past ten years have been marked by a decided increase in the use of the artistic Comet type of flower. Many asters of American origin, adapted to American market conditions, have been widely disseminated. "Non-lateral" strains of Branching asters, devoid of side buds, have been produced to meet a need of the florists, and as a result of careful seed-growing, the semi-double aster has nearly disappeared from field and garden. The frequent accidental crossing and re-crossing of widely differing types and a natural tendency toward variation are constantly furnishing material for improvement when asters are grown in quantity and variety. Recent introductions of types of asters show increased size and vigor of plant commonly attributed to a more or less remote Branching cross. Some of the most valuable introductions, like the Rochester and the Crego Pink, appear to be a combination of a Branching plant and a Comet flower.

The Comet aster group has not taken the place, commercially, to which its great beauty would entitle it, because its very long slender petals make it less lasting as a cut-flower than flowers with broader, shorter petals. The slender stems usually correlated with this type of flower, although attractive in cut-flowers, are undesirable in the field. Beautiful single asters have been introduced from Europe, but so far have made little headway against the American prejudice in favor of double flowers.

#### Classes of asters.

The typical Branching aster is pyramidal in form, large and vigorous, with many lateral branches. It blooms at the close of the season. The abundant leaves are broad and large. The flower is large and deep with the long, rather broad petals irregularly arranged, giving it a soft appearance. The flowers bear well the rough handling incident to ordinary shipping, and if cut before fully mature will last for two weeks. The size and vigor of plant enable the amateur to get fair results with indifferent culture. Modifications of the original type may now be had with flowers having petals variously folded, incurved or whorled and with plants varying to upright in growth and entirely devoid of the many branches that gave the type its name.

The Comet flower is characterized by having petals that are long and narrow and strongly recurved. This gives it a charming light feathery appearance. Originally it was of medium size and bloomed in midseason on upright plants. Comet flowers may now be had on every sort of aster plant. The season includes the earliest and the latest, and the largest aster flowers now grown are of the Comet type.

426. China aster of the Quilled type. ( $\times \frac{1}{2}$ )

Queen of the Market was the first of the distinctively early varieties and is still the most largely grown. The plants are open and spreading and the flowers, while smaller and flatter than those of the Branching, have the same general character.

Victoria and Truffaut (or Pæony-flowered Perfection) were for many years the standard varieties and are still grown to some extent. The plants are upright and bloom in midseason. The petals of the Victoria aster are reflexed at the ends; those of the Truffaut aster strongly incurve, making a ball-shaped flower. Both varieties comprise every shade of color known in asters, and these are duplicated in Giant and Dwarf classes.

#### Cultivation.

Asters thrive in any soil that can be kept in a good mechanical condition. The large late asters are usually the most satisfactory to the amateur. They may easily be grown from seed sown as early as possible in the open ground. Asters transplant readily.

If the plants are started in boxes in the house, the soil should be allowed to dry off on the surface as much as possible between waterings to prevent damping off. Midseason varieties may be grown successfully in this way; but the very earliest varieties need to be started in a greenhouse or an early hotbed.

For market, the extra-early kinds should be sown eight to ten weeks before the soil will permit planting out. They should be kept growing thriftily with a night temperature of about 50° and afterward be thoroughly hardened off in coldframes so that they will not be injured by late frosts after planting out. The soil should be quite as rich as that used for profitable crops of onions or celery; otherwise the flowers will be too short-stemmed. Midseason varieties for market succeed well when started in a mild hotbed. Give plenty of air and avoid overwatering. The last sowing of late varieties is made in the open ground.

When growing in large quantities, the seed is sown with a garden drill in rows a foot apart. A transplanting machine, drawn by horses, is used for setting the plants in the field.

The most destructive diseases in the commercial cultivation of asters are various forms of stem-rot. They are of fungous origin and are induced by allowing the plants to remain moist too long at a time. The infection usually takes place in the seed-row, but often no effect is noticed until the plants are nearly full-grown, when they suddenly wilt and die. Covering the soil in the seed-boxes with clean sand, which can be kept dry between waterings, is an effective aid in the prevention of damping-off and stem-rot. The "yellow disease" causes the plants to have a bleached appearance and to make a spindling growth. It is a derangement of the functions of plant-growth caused, so far as known, by irregularity in the moisture-supply. Thorough cultivation of the soil is the best preventive. The presence of "orange rust" is shown by conspicuous orange-colored pus-

427. China aster, Victoria Needle type. ( $\times \frac{1}{2}$ )

tules on the under side of the leaves. The disease can be held in check by thorough spraying with a fungicide. The Pennsylvania blister beetle is so destructive to asters south of the latitude of New York that it is now commonly known as "the aster beetle." It is a large, soft-bodied, black beetle. It feeds on the flower. Spraying with an arsenical poison will control the beetles in the field. Frequent hand-picking can be practised in the garden. The season of this insect is short. The "tarnished plant-bug" causes extensive damage to asters, most of which is commonly attributed to other causes. The inconspicuous yellowish brown insect, smaller than a house-fly, easily escapes notice. The terminal buds that are punctured by the bug, usually die. Frequently the branch becomes diseased and sometimes the entire plant is dwarfed and sickened. The insects cannot be poisoned, but kerosene emulsion and whale-oil soap are effectual deterrents. Asters growing in partial shade are seldom injured by plant-bugs.

GEO. ARNOLD.

**ASTEROLINOSYRIS** (name derived from *Aster* and *Linosyris*). *Compositæ*. A plant with "rosy-mauve petals, mixed yellow," reputed to be a hybrid between *Aster acris* and *A. Linosyris* (*Linosyris vulgaris*). Apparently a bi-generic hybrid. *Asterolinosyris Willmottiae* is the only species offered, and apparently not by American dealers.

N. TAYLOR.

**ASTILBE** (Greek, meaning *not shining*). *Saxifragaceæ*. Includes *Holèia*. Ornamental perennial herbs grown chiefly for their showy panicles of white or pink flowers.

Leaves ternately 2-3-pinnate; fls. perfect or dioecious; calyx 5-, rarely 4-lobed; petals as many, rarely wanting; stamens 10 or 8, rarely 5; pistils 2 or 3, distinct or partly connate; fr. 2 or 3 dehiscent follicles with many minute seeds.—About 14 species in Cent. and E. Asia, Java and E. N. Amer. They look much like *Aruncus* (which see), and are often called *Spiræa*. *Aruncus* and *Spiræa* are rosaceous genera, and are characterized by many stamens and usually by several to many separate pistils, whereas *Astilbe* has 10, 8 or 5 stamens (twice the number, or of the same number, as the petals), and a 2-3-lobed pistil (which finally separates into more or less distinct follicles). *Astilbe* and *Aruncus* are so much alike that they are often confounded by horticulturists.

The *astilbes* are perennial herbs, mostly rather tall with handsome compound bright green foliage and small white, pink or almost purple flowers in slender or dense spikes forming large terminal feathery panicles.

They are hardy plants of great merit. They are easily grown in any well-made border and like rich good soil and plenty of water during the growing period. They give conspicuous masses of bloom in summer.

Propagation is mostly by division; also by seeds sown early in spring in the greenhouse; they germinate after two or three weeks; the young seedlings must be pricked off several times and later planted out in

frames or in the open ground. The young plants will flower the second year.

*Forcing of astilbe*.—Few herbaceous plants force with greater ease than *Astilbe japonica*, and its var. *compacta*; but three weeks longer time should be given the latter fully to develop its feathery spikes. *Astilbes* are so easily and cheaply imported that for the commercial florist it is cheaper to buy than to divide and grow his own plants. When first received, the clumps of roots should be stored, with a little earth or moss between the roots and a little soil over the crown, until the florist is ready to pot them. No amount of freezing does them the slightest harm; but the boxes or flats in which they are stored are best covered with a little straw or litter, and should have the full benefit of rain or snow to keep the roots from drying. From potting or bringing into the greenhouse, it requires from ten to fourteen weeks to bring them into flower, according to the earliness of the season at which they are wanted in flower. The quality of soil is of no consequence, provided it is light and easily handled. They need water in great abundance. Temperature is also of little consequence. Anything above 50° at night will do; but it is best not to flower them in a higher temperature than 60°, or they will quickly wilt when cut or used for decorations. From the time the sprays begin to show white color until they are fully developed, every *astilbe* should stand in a saucer in which there should be constantly an inch of liquid manure. When sold for window plants or for decoration, *astilbes* are often disappointing. It is merely want of water. Before the full development of the shoots and leaves, they are easily hurt by tobacco smoke, and should be covered with paper or well wetted when fumigation is necessary. Aphis, spider or thrips never trouble *astilbe*. As a border plant, *astilbe* is one of the best of our hardy herbaceous plants; but the feathery plume obtained in the greenhouse is much shorter, more compact, and lacks the pure whiteness of the outdoor-grown specimens. (Wm. Scott.)

428. *Astilbe japonica*.

A. Color of petals white or yellowish white (or changing to pinkish in *A. Thunbergii*), rarely petals wanting.

B. Petals wanting; stamens 5.

1. *rivularis*, Ham. Rhizome creeping; st. 3-5 ft.: lvs. 2-ternate, the lfts. ovate, dentate 1-3 in. long; the petioles tawny-hairy like the sts. at the base; fls. yellowish white, in large spikes, which are disposed in panicles; stamens 5, pure white. Nepal, W. China. Gn. 48, p. 355.—Attractive, border species, blooming late. Probably needs protection.

BB. Petals present at least in the staminate fls.; stamens 10.

c. Stamens exceeding the petals; tall, 3-6 ft. high.

2. *bitemata*, Brit. (*A. decandra*, Don. *Tiarèlla bitemata*, Vent.). Somewhat pubescent, 3-6 ft.: lvs. 2-3-ternate, the lfts. ovate and cordate or abrupt at base, sharp-serrate, 2-5 in. long; fls. yellowish white, in a large (10-12 in. long) racemose panicle; petals linear, spatulate in the staminate fls., small or wanting in the perfect ones. June. Woods, Va. and S. B.B. 2:170.—Often confounded with *Aruncus sylvestris*, which has numerous stamens not exceeding the broad petals.

3. *grándis*, Stapf. St. 4-6 ft.: lvs. ternately pinnate or 3-pinnate; lfts. ovate to oblong-ovate, doubly serrate, 2-4 in. long, slightly hairy, petiole hairy; panicle 2-3 ft. long with spreading branches; fls. crowded, petals 3 times as long as calyx, stamens longer than petals. July. Cent. China. G.C. III. 38:426. R.B. 33:232.

cc. Stamens shorter than petals: st. 1-4 ft.

d. Lfts. distinctly cuneate at the base: petals about twice as long as calyx.

4. *japónica*, Gray (*Hotëia japónica*, Morr. & Decne. *H. barbata*, Morr. & Decne. *Spiræa japónica*, Hort.). Fig. 428. Erect, 1-3 ft., hairy on the petioles and nodes; lvs. 3-2-ternate, petiole reddish; lfts. ovate-acute, tapering to the base, serrate; fls. white, in a pubescent racemose panicle with somewhat recurved branches; sepals obtusish, as long or slightly longer than pistils. Japan. B.M. 3821. Gn. 48, p. 366. Mn. 5:174.—Commonly known as a spring glasshouse plant in this country, but hardy in the open. There are various cult. forms, as var. *grandiflora*, Hort., with larger and denser panicle; var. *compácta*, Hort., the panicle more compact; var. *multiflora*, Hort.; var. *variegata*, Hort., with variegated lvs.; var. *purpurea*, Hort., with purple-shaded foliage.

dd. Lfts. rounded at the base or occasionally broadly cuneate: petals  $2\frac{1}{2}$ -4 times as long as calyx.

5. *Lemoinei*, Lemoine. Foliage graceful, standing  $1\frac{1}{2}$  ft. high, with lfts. broad-oval, dentate and crimped, satiny green, hairy; fls. with white petals and 10 pink stamens, very numerous, in plume-like clusters, disposed in panicles  $1\frac{1}{2}$  ft. long. Gn. 48, p. 355. R.H. 1895, p. 567. A.F. 11:459.—Garden plant, a hybrid of *A. Thunbergii* and *A. astilboides*. Hardy, and forces well.

6. *astilboides*, Lemoine (*Spiræa astilboides*, Moore. *Spiræa Aruncus* var. *astilboides*, Hort., not Maxim. *A. aruncoides*, Lemoine). Fig. 429. St. 2-3 ft.: lvs. 2-3-pinnate; lfts. ovate to ovate-oblong, 1-2 $\frac{1}{2}$  in. long, doubly and sharply serrate, hairy; fls. white, crowded in dense spikes, forming a panicle, with straight spreading branches; sepals acutish, shorter than pistils; petals linear-oblong, at least  $2\frac{1}{2}$  times as long as sepals. Intro. from Japan. G.C. II. 14:113.—Var. *floribunda*, is supposed to be a cross of this species and *A. japonica*.

7. *Thunbergii*, Miq. St. 1-2 ft.: lvs. 2-3-pinnate, the lfts. slender-stalked, ovate,  $1\frac{1}{2}$ -3 $\frac{1}{2}$  in. long, serrate, yellowish green, hairy; fls. white, on reddish stalks, often changing to pink, in clusters on rather slender spikes forming a spreading panicle; petals  $2\frac{1}{2}$  times as long as the calyx. Japan. F.M. 1881:457. R.H. 1895, p. 565.—A graceful plant. Forces well.

8. *chinensis*, Franch. & Sav. (*Hotëia chinensis*, Maxim.). Plant  $1\frac{1}{2}$ -2 ft., graceful: lvs. ternately 2-3-pinnate; lfts. ovate-lanceolate, doubly serrate, 2-3 $\frac{1}{2}$  in. long, hairy; fls. in a branchy, rather narrow panicle; petals linear-spatulate, white, 3 or 4 times as long as the yellowish white or pink calyx; stamens lilac; anthers blue. July. China. M.D.G. 1907:547.—Possibly a form of the preceding.

9. *rosea*, Van Waveren & Kruijft (*A. hybrida rosea*, Arends). A hybrid between *A. chinensis* and *A. japonica*. Similar to *A. japonica* in habit, but fls. pinkish. The two best known forms are var. Peach Blossom, with lighter pink fls., R.H. 1908, p. 341, and var. Queen Alexandra, with deeper pink fls. M.D.G. 1911:53.

AA. Color of petals pink.

10. *Davidii*, Henry (*A. chinensis* var. *Davidii*, Franch.). St. 4-6 ft.: lvs. ternately pinnate or bipinnate; lfts. ovate to ovate-oblong, 1-1 $\frac{1}{2}$  in. long, coarsely

and unequally serrate; panicle about 2 ft. long, narrow, with ascending, spike-like slender branches, the lower 4-5 in. long; fls. nearly sessile, crowded, fascicled, bright rose-pink; petals linear; stamens 10, shorter than petals with violet filaments and dark blue anthers. July. N. and Cent. China. B.M. 7880. G.C. III. 32:103. R.H. 1907:40. Gn. 72, p. 179. M. D.G. 1907:545.

11. *rubéila*, Lemoine. A hybrid between *A. Lemoinei* and *A. Davidii* (or *A. Lemoinei* × *A. chinensis* × *A. Davidii*). Similar to *A. Lemoinei*, but fls. rose-colored; panicle more compact than in *A. Davidii*. R.B. 34:28.

—Other forms

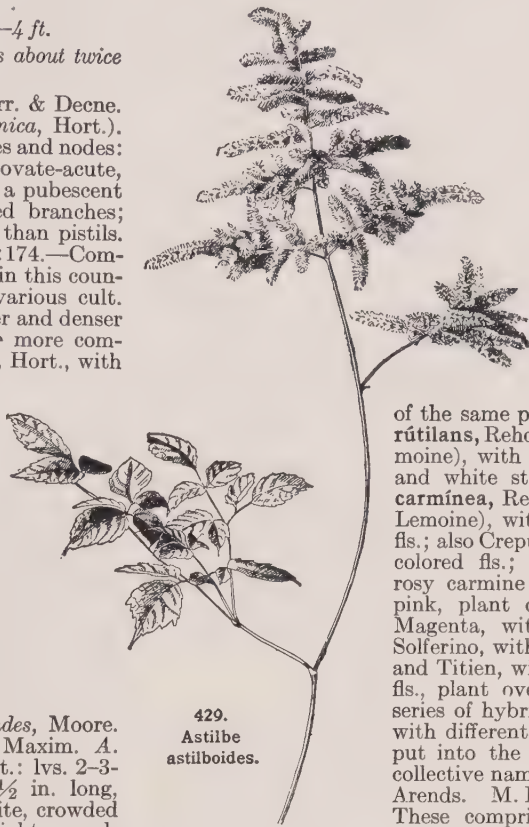

of the same parentage are var. *rutilans*, Rehd. (*A. rutilans*, Lemoine), with rosy-carmine fls. and white stamens, and var. *carminea*, Rehd. (*A. carminea*, Lemoine), with violet-carmine fls.; also *Crepusculæ*, with flesh-colored fls.; *Lumineux*, with rosy carmine fls. changing to pink, plant over 3 ft. high; *Magenta*, with carmine fls.; *Solferino*, with violet-pink fls.; and *Titien*, with delicate pink fls., plant over 3 ft. high. A series of hybrids of *A. Davidii* with different species has been put into the trade under the collective name of *A. Arendsii*, Arends. M.D.G. 1907:546.

These comprise the following crosses: *A. Davidii* × *A. astilboides*, with rosy-lilac fls. in loose and graceful feathery panicles; stamens and petals much exceeding the sepals; here belong the varieties *Juno*, with purplish pink fls., plant over 3 ft. high; *Venus*, also with purplish pink fls.; *Vesta*, with rosy lilac fls.; and *Ceres*, with lilac-pink fls. *A. Davidii* × *A. japonica*, with creamy white to pale pink or salmon fls. in dense spikes; petals and the pink stamens not much exceeding the sepals; here belongs *Rose Perle*. *A. Davidii* × *A. rosea*, similar to *A. japonica* in habit, with purplish pink to salmon or nearly white fls.; this cross may be classed with *A. rubella*. *A. Davidii* × *A. Thunbergii*, taller, 4-5 ft. high with large feathery panicles, their branches nodding at the tips; fls. pale pink to white.

12. *rubra*, Hook. & Thoms. St. simple, 4-6 ft., long-hairy; lvs. 2-ternate; lfts. oblique-ovate, more or less cordate, 1-3 in. long, sharp-serrate; fls. numerous, rose-red, in compact, robust panicles, with the main branches erect and numerous short lateral branchlets about 1 in. long; stamens 10, shorter than petals. India. B.M. 4959.—Needs protection. Little known in Amer.

*A. crenatilobata*, Small (*A. decandra crenatilobata*, Brit.). Allied to *A. decandra*. Lfts. crenately toothed, the terminal one usually 3-lobed. N. C.—*A. simplicifolia*, Makino. Low, not exceeding 1 ft.: lvs. simple, ovate, deeply lobed or incised, about 3 in. long; panicle slender and narrow, the branches short, with star-like white fls. Japan. G.C. III. 48:294; 52:101.—*A. virescens*, Hutchins. Allied to *A. rivularis*. Lfts. obliquely cordate-ovate, 3-4 in. long, denticulate; panicles much branched with small greenish white fragrant fls.; petals wanting; stamens 10. China.

ALFRED REHDER.†

**ASTRÁGALUS** (ancient Greek name of some shrub). *Leguminosæ*. MILK VETCH. Hardy herbs or subshrubs, now and then seen in plantings.

Leaves mostly odd-pinnate, sometimes simple: fls. in spikes or racemes, yellow, purple or white; calyx tubular, its teeth nearly equal; petals clawed, the standard erect; stamens in 2 clusters, the anthers similar: pods fleshy, leathery or papery, not much swollen, as they are in the membranous-legged *Phaca*, the nearest relative.

430. *Astragalus hypoglottis*.  
( $\times \frac{1}{2}$ )

—About 1,500 species. Many kinds are cult. in the Old World, but those described below are the only kinds commonly sold in Amer. The loco-weed of the prairies, which is said to poison cattle, is *A. mollissimus*. For those below and many others, the student is referred to Britton and Brown's Illustrated Flora, Nelson's Manual of Rocky Mountain Botany, and Rydberg's Flora of Colorado. The botanical characters are mostly found in the pods.

*Astragalus*es prefer a light, porous soil and no shade. The dwarfier kinds may be placed in the front of the border or in the rockery.

Propagation is chiefly by seeds, which germinate slowly, or by careful division in early spring. Many kinds are likely to die if divided or transplanted, as they are mycorrhizal plants, much dependent on a semi-parasitic organism, which is better left undisturbed.

*A. Fls. yellow.*

**alopecuroides**, Linn. St. erect, strict; height 2–5 ft.: fls. ovate-lanceolate, pubescent: fls. in thick ovate-oblong spikes, on short, axillary peduncles. Siberia. B.M. 3193.

**carolinianus**, Linn. (*A. canadensis*, Linn.). One to  $3\frac{1}{2}$  ft.: fls. 15–31, glabrous or slightly pubescent,

elliptic or oval, obtuse or slightly emarginate at apex: fls. yellowish,  $\frac{3}{4}$ –1 in. long, in a dense spike: pods 2-celled, coriaceous, sessile, terete and glabrous. July, Aug. E. N. Amer. L.B.C. 4:372.

**Drummondii**, Douglas. Erect, 10–20 in.: fls. 19–33, glabrous, oblong or sometimes oblanceolate, and obtuse: fls. yellowish white, the keel rarely tinged with purple, 1–1½ in. long, in a loose spike: pods 1-celled, distinctly stalked, glabrous and grooved. June, July. Plains of Cent. N. Amer. Hook. Fl. Bor. Amer. 57.

*AA. Fls. not yellow.*

*B. Sts. trailing.*

**monspessulanus**, Linn. St. trailing; height 9 in.: fls. purple, purplish or white, in smaller and looser heads than the above. Eu. B.M. 375.

*BB. Sts. erect or merely decumbent, not trailing.*

*c. Plants not spiny.*

*d. Pods 1-celled.*

**flexuosus**, Hook. Four to 15 in., leafy-std. and finely hairy: fls. 9–21, linear, oblong or oblanceolate, obtuse or emarginate: fls. purplish,  $\frac{1}{2}$ –¾ in. long, the peduncles exceeding the lvs.: pods 1-celled, sessile, cylindric, linear or linear-oblong. June–Aug. Plains of Cent. N. Amer.

**alpinus**, Linn. Height 6–15 in.: fls. 13–25: fls. violet, keel darker: pods 1-celled, black-pubescent. Northern and Arctic regions around the world.

*DD. Pods more than 1-celled.*

**hypoglottis**, Linn. Fig. 430. Height 3–24 in.: fls. 17–25: fls. violet-purple, 6–10 lines long, in dense heads: pods 4–5 lines long, 2-celled, densely villous with white hairs. Eu., Asia, and from Kan. west to Nev. and north to Alaska.—Also a white variety excellent for pots.

**caryocarpus**, Ker-Gawl. Perennial, the whole plant tomentulose: sts. decumbent, ultimately ascending: lvs. alternate, distant, with 17–25 fls.: fls. pale violet-purple, the calyx about half as long as the corolla: seeds several in each cell. La. B.R. 176.

**adsurgens**, Pall. (*A. Laxmanii*, Jacq.). Fig. 431. Small, erect or mostly decumbent plant, with 15–25 fls., which are oval to linear-oblong, obtuse and rarely emarginate: fls. purplish,  $\frac{1}{2}$ –1 in. long, the peduncles exceeding the lvs., the spikes dense: pods 2-celled, sessile, oblong and pointed. June, July. Plains of Cent. N. Amer. Jacq. Hort. Vind. 3:37 (as *A. Laxmanii*).

*CC. Plant spiny: fls. white.*

**hórrida**, Boiss. A low bristly perennial with spiny lvs. composed of 7–8 pairs of broad fls.: fls. white in a dense, long-stalked, spike-like cluster. Persia.—Curious and rare, rather than attractive.

*A. racemósus*, Pursh. Zigzag, erect st.: fls. 17–21: fls. yellowish in loose racemes. July. Plains of Cent. U. S.—*A. Robbinsii*, Oakes. Erect and glabrous: fls. 9–25: fls. in loose racemes, white or purple: pods 1-celled, flattened. Suitable for rocky places. June, July. N. E. U. S.—*A. Shortianus*, Nutt. Silvery canescent: fls. 9–15: fls. blue or violet: pods sessile, 1-celled, strongly curved upward. May, June. Plains of Cent. U. S.

N. TAYLOR.

**ASTRÁNTIA** (name in allusion to star-like appearance of umbels). *Umbelliferae*. MASTERWORT. Perennial garden plants, grown for the odd and ornamental umbels and attractive habit.

Glabrous and erect low herbs with dark-colored aromatic roots: lvs. palmately lobed or dissected, petioled, the st.-lvs. often sessile and more simple: fls. polygamous, the sterile long-pedicelled and the fertile short-pedicelled; calyx with 5 foliaceous lobes, more or less tuberculate; petals oblong-ovate, connivent: fr. compressed.—Perhaps a half-dozen species, in Eu. and W. Asia, bearing fls. in leafy-involved umbels and umbellules, the fls. being white, rose-colored or bluish. The astrantias grow a foot or more high, making

interesting branching plants for the border, particularly in moist places. Prop. by seeds, and easily by divisions in autumn or spring.

**carriõlica**, Wulf. About 1 ft.: radical lvs. 5-7-lobed, the lobes oblong-acuminate, serrate; fls. white or blush; involucre of about 12 entire whitish parts with green red-tinged line. Eu. Attractive. June, July.

**màjor**, Linn. The commonest species in cult.: 1-3 ft.: radical lvs. 5-lobed, the lobes ovate-lanceolate and more or less parted and toothed, acute; fls. pinkish, or rose, or white; involucre of 20 or less linear-lanceolate entire leafy parts; calyx-lobes lanceolate and spinulose, exceeding the petals. Eu.—Thrives by running water and in partial shade. May, June.

**Biebersteinii**, Traut. Small: radical lvs. 3-parted, the middle lobe oblong or obovate and more or less 3-lobed, sharp-serrate; involucre parts oblong, entire or nearly so, equaling the umbel; calyx-lobes lanceolate-acute, equaling the petals. Caucasus.

*A. helleborifolia*, Salisb. (*A. heterophylla*, Willd., *A. maxima*, Pall.). 2 ft. or less: radical lvs. 3-lobed, serrate; fls. pink; involucre of about 12 ovate-lanceolate bristly parts. Caucasus.—*A. minor*, Linn. 8-10 in.: radical lvs. 7-9-lobed, toothed; fls. white; involucre white. Eu.

L. H. B.

**ASTRAPÆA**: *Dombeya*.

**ASTROCARYUM** (Greek, *astron*, star, and *karyon*, nut; referring to star-like arrangement of the fruits). *Palmaceæ*, tribe *Bactridæ*. Spiny palms, stemless or with a short, or tall, ringed caudex.

Leaves terminal, pinnately parted; segms. approximate, equidistant or fasciculate, lanceolate-acuminate or attenuate to the obliquely truncate apex, plicate, whitish beneath, the terminal ones free or confluent, the spiny margins recurved at the base; petiole very short; sheath short, open, the spines of nearly all parts of the plant, in some cases, nearly a foot long; spadices short or long, the finely divided branches pendulous, thickened at the base, thence very slender, long, naked, the floriferous naked basal portion, as it were, pedunculate; spathes 2, the lower one membranous, deciduous, the upper fusiform, coriaceous or woody, open on the ventral side, persistent; bracts of the female fls. broad, imbricated like the bractlets; pistillate fls. with a stipitate male one on either side: fr. rather large, ovoid or subglobose, beaked, smooth or spiny, red or orange.—Species 30. Trop. Amer.

431. *Astragalus adsurgens*. ( $\times \frac{1}{2}$ )

*Astrocaryums* are elegant palms of medium height, very suitable for moderate-sized conservatories. *A. Murumuru*, *A. mexicanum* and *A. argenteum* are the kinds most commonly met with in collections. The leaves are pinnate, spiny on both sides, even in very young plants, and in small plants, at least in some of the species, the segments are narrow, four or five pairs of these alternating with two very broad ones. *A. argenteum* has the under surfaces of the leaves of a much lighter color than the others.

In a young state, the plants require the temperature of the stove, and after attaining the height of a few feet they may be best grown in a warmhouse, and given plenty of water; also a humid atmosphere. Specimens 8 to 10 feet high fruit freely.

Propagation is by seeds, which are slow in germinating. The soil in which they are sown should be changed occasionally, to prevent it from becoming sour. Be careful not to overpot, or the fleshy roots will decay. G.C. II. 22:522. See *Palms*.

*A. Lvs. scurfy, at least beneath or on the petioles.*

**Mûrumuru**, Mart. Lvs. 9-12 ft. long; segms. lanceolate, somewhat falcate, rich green above, silvery beneath; sts. 12-15 ft. high, densely covered with stout, black spines 6 in. long. Brazil. I.H. 22:213.

**argenteum**, Hort. Petioles and under surface of the lvs. covered with silvery white scurf: lvs. arching, wedge-shaped, 2-lobed, distinctly plicate, bright green above; petioles with numerous dark, spreading spines 1 in. long. Colombia. F.R. 3:569.—Perhaps more correctly named *A. Malybo*, Karsten.

**filulære**, Hort. Small, slender: lvs. erect, narrowly cuneate, with 2 divergent lobes, inversely sagittate; petioles densely scurfy; rachis scurfy on both sides; spines numerous on the petioles and rachis, and on the principal nerves above; brown. Country unknown.

*AA. Lvs. not scurfy.*

**Àyri**, Mart. Trunks 18-30 ft. high, 8-12 in. diam., usually cespitose: lvs. 15 ft. long, equally pinnatisect to the apex; petiole plano-compressed, membranaceous on the margins, densely scaly and with scattered spines; lower segms. over 3 ft. long,  $1\frac{3}{4}$ -2 in. wide, 2 in. apart, the upper ones 2-2 $\frac{1}{2}$  ft. long, 1 in. wide,  $1\frac{1}{4}$  in. apart, conduplicate at the base, linear, long, attenuate, pointed, minutely and remotely spiny along the margins, white-tomentose below. Brazil.

**mexicanum**, Liebm. St. 4-6 ft. high, cylindrical, thickly covered with rings of black, straight, 2-edged spines: petiole 2 ft. long, 4-sided, the 2 upper sides concave, clothed (as is the rachis) with straight black spines; blade 6 ft.; segms. 15-18 in. long, 1 in. wide, alternate, broadly linear, acute, straight, white beneath, with deciduous black spines along the margins. Mex.

*A. granatense*, Hort., is an unidentified trade name.

J. G. SMITH and G. W. OLIVER.

N. TAYLOR.†

**ASYSTÀSIA** (obscure name). Including *Henfrèya*, *Dicentranthèra* and *Mackàya*. *Acanthaceæ*. Hothouse or greenhouse evergreen herbs and shrubs.

Plants erect or scandent: lvs. membranaceous, entire: corolla-tube straight or curved, the spreading limb 5-lobed and nearly or quite regular; stamens 4, unequal; stigma blunt or minutely 2-lobed; fls. white, blue or purple, in axillary or terminal clusters, often very showy.—About 20 species in the Old World tropics. Require the general treatment of *Justicia*, in intermediate or warmhouses.

**bèlla**, Benth. & Hook. (*Mackàya bèlla*, Harv.). Glabrous, upright sub-shrub: lvs. ovate-oblong, acuminate, spreading, short-stalked, sinuate-toothed: fls. lilac, 2 in. long, with a long tube below the flaring throat, the spreading segms. ovate-obtuse, disposed on one side of a raceme 5-8 in. long. S. Afr. B.M

5797.—A beautiful plant, rarely seen, and thought to be difficult to manage; but it seems to flower readily in fall in our climate, if rested during the previous winter and brought on in the summer. Prop. by cuttings of firm wood in spring or summer. Young plants in small pots often bloom well.

*A. coromandeliana*, Nees (*A. comorensis*, Bojer. *A. violacea*, Dalz. *Justicia gangetica*, Linn.). Zigzag sub-shrub: lvs. ovate-cordate, wavy: fls. purple, nearly sessile, in 6-10-fl. raceme. India. B.M. 4248. P.M. 14:125. F.S. 2:179.—*A. scandens*, Lindl. (Henfrey *scandens*, Lindl.). Climbing: lvs. obovate to ovate, thick, entire: fls. large, yellow, white and bluish, in a thyrs. Afr. B.M. 4449. B.R. 33:31. F.S. 3:231. L. H. B.

ATACCIA: *Tacca*.

**ATALANTIA** (*Atalantia*, one of the Hesperides). *Rutaceæ*, tribe *Citrææ*. Woody plants, now receiving

attention in America as stocks for citrus fruits, and as possible parents in breeding new forms of such fruits.

Small trees or shrubs, usually spiny, with persistent coriaceous simple lvs. having prominent netted veins and wingless or very narrowly winged petioles jointed at base of lf.: fls. usually pentamerous, with the stamens free or united into a tube, twice as numerous as the petals; ovary 3-5-celled, with 1 or 2 ovules in each cell: fr. like a small orange with a lemon-like skin. In the typical species, the pulp-vesicles fill the segms., but in some dry-fruited species they are rudimentary; these species constitute the subgenus *Rissoa*.—Twelve or 15 species are known, ranging from India through the Malayan peninsula to Austral.

432.

Leaf of *Atalantia citrioides*. ( $\times \frac{5}{8}$ )

*A. Subgenus Euatalantia. Cells of fr. lined with pulp-vesicles.*

**monophylla**, DC. (*Limonia monophylla*, Roxbg., not Linn.). A large shrub or small tree, native to India, Ceylon, Burma, Siam and Indo-China, usually spiny: lvs. glabrous, or sometimes pubescent, 1-3 in. long; petioles short, slightly or not at all winged: fls. borne in axillary panicles; calyx irregularly lobed, split to the base on one side; petals usually 4, stamens 8, the filaments connate and forming a completely closed tube; ovary 3-5-celled: fr. from  $\frac{1}{2}$ – $\frac{3}{4}$  in. diam., with a skin like a lime, globose, with several cells (generally 4), each usually containing 1 seed and filled with pulp-vesicles, making the fr. much like a miniature orange. India, Ceylon, farther India. Ill. Roxbg. Pl. Corom., pl. 83. Wight, Icones, pl. 1611. Engl. in Engl. and Prantl. Nat. Planzenf. III. 4:191; fig. 111, C.D.—This tree, still little known outside of India and Ceylon, is the

433.

Cross-section of ovary of *Atalantia citrioides*. ( $\times 1$ )

type of the genus *Atalantia*, and one of the promising species for trial as a stock on which to graft other citrus frs., and also for use in breeding new types of citrus frs. The frs. yield an oil which in India is considered a valuable application in chronic rheumatism.

**macrophylla**, Kurz. (*A. monophylla* var. *macrophylla*, Oliver). A small or medium-sized tree, native to the Andaman Is. and Burma, having ovate-

elliptical emarginate lvs.  $1\frac{1}{2}$ –4 in. long and  $1-2\frac{1}{2}$  in. broad: fls. on short axillary racemes; calyx irregularly lobed, split to the base on one side as in *A. monophylla*; stamens connate and forming a tube: fr. large, said to reach  $1\frac{1}{2}$ –2 in. diam. Andaman Is., Burma, Malay Peninsula, Bangka Isl.—Little known and is chiefly interesting because of the large size of its frs. Kurz, in his "Forest Flora of British Burma," says of this species:

"Berries globose, the size of a wood-apple, glabrous," and gives the size of the wood-apple as  $1\frac{1}{2}$ –2 in. diam. A tree brought from the island of Bangka, east of Sumatra, and now growing at the Botanical Gardens at Buitenzorg, Java, is considered by Hochreutner to belong to this species. It is of remarkable size, being a beautiful round-topped tree 40 ft. high with a deeply furrowed trunk 6 ft. in circumference, forking at 3 ft. from the ground and branching profusely at  $6\frac{1}{2}$ –10 ft. No other species of *Atalantia* is known to reach this size or to bear frs. so large. This species is of unusual interest for trial as a stock and also for hybridizing with other citrus frs.

**citrioides**, Pierre. A small tree native to Indo-China, usually spiny, having glabrous emarginate oval lvs.  $2-3\frac{1}{2}$  in. long (Fig. 432): calyx cup-shaped, not split to the base; stamens connate, forming a tube; ovary usually 3- or 4-celled: fr. resembles a small orange about  $\frac{3}{4}$  in. diam., with a roughened glandular skin; cells filled with pulp-vesicles and contain usually a single seed about  $\frac{3}{4}$  in. long (Fig. 433). Ill. H. Lecomte Fl. gén. de l'Indo-Chine, Vol. I, pl. 24, fig. C. 5, 6.—This interesting species is native to Cochinchina and Cambodia and has recently been intro. into this country, where it will be tested as a stock and for breeding purposes. Its close relationship to *Citrus* is shown by the fact that it grows well when grafted on grapefruit.

**racemosa**, Wight. A shrub or small tree, differing from *A. monophylla* chiefly in having a regular calyx not split down one side. S. India, Ceylon. Ill. Hook. J. bot. Vol. I, pl. 122: Wight, Icones, pl. 71.

**AA. Subgenus, Rissoa**, n. subg., named for A. Risso, b. Nice, 1777, d. 1845, a well-known writer on citrus frs. *Rissoa*, Arnott, 1836 as a genus. Like *Euatalantia*, but with dry frs., the cells being nearly filled with 1 or 2 large seeds; pulp-vesicles rudimentary and greatly reduced in number.

**ceylónica**, Oliver (*Rissoa ceylónica*, Arn.). Fig. 434. A much-branched spiny shrub or small tree native to Ceylon and India: lvs. lanceolate emarginate,  $1\frac{1}{4}$ –3 in. long: fls. borne in crowded cymes; calyx not split on one side; stamens free, alternate ones longer; ovary usually 2-celled with 2 ovules in each cell: frs. about  $\frac{1}{2}$ – $\frac{3}{4}$  in. diam., dry, having only rudimentary pulp-vesicles; containing from 2-4 very large rounded seeds. Ceylon.—This species is of interest chiefly for trial as a stock, since its large seeds would be likely to produce very vigorous seedlings. The dry fr. renders it unpromising for breeding purposes. The figure is from a specimen grown at the Hope Garden, Jamaica.

**Guillauminii**, Swingle. A small spiny tree, 10-13 ft. high: young branches angular and pubescent: lvs. oval, more or less pointed at both ends, 2-4 in. long: fls. unknown: frs.  $\frac{3}{4}$ –1 in. diam., 3-celled, 2 large seeds in each cell, pulp-vesicles rudimentary. Tonkin. Ill. Notulae systematica. H. Lecomte, Vol. II, p. 162, fig. 1.—A little-known species, interesting on account of its large frs. Because of its large seeds, it should yield vigorous seedlings.

434. *Atalantia ceylonica*. ( $\times \frac{1}{2}$ )

**simplicifolia**, Engl. (*Amyris simplicifolia*, Roxbg. *Atalantia Roxburghiana*, Hook. f.). A spineless shrub or small tree: lvs. very large, 4-6 in. long,  $1\frac{1}{2}$ -2 $\frac{1}{2}$  in. wide, elliptic, pointed at both ends: stamens free; ovary 2-celled: fr. spherical, rough-skinned,  $\frac{1}{2}$ -1 in. diam., with large seeds. Malay Peninsula. Ill. Wight, *Icones*, pl. 72. —An interesting species because of its unusually large lvs.

Imperfectly known species: *A. caudata*, Hook. f. Lvs. caudate-acuminate, narrowed at base: ovary 2-celled. India.—*A. puberula*, Miq. Lvs. narrowly oblong-emarginate: twigs, petioles, lf.-bases and midrib puberulous; perhaps a form of *A. monophylla*.

WALTER T. SWINGLE.

**ATAMASCO LILY:** *Zephyranthes*.

**ATHANÁSIA:** *Lonas*.

**ATHROTÁXIS** (name alludes to the crowded cone-scales). Sometimes spelled *Arthrotaxis*. *Pinaceæ*. Evergreens, allied to *Cryptomeria*, *Sequoia* and *Sciadopitys*, suitable for planting South, or for use as tub specimens in coolhouses.

Trees, densely branched, monœcious: lvs. small, either short, blunt, scale-like and appressed, or lanceolate and somewhat loosely disposed: staminate fls. in imbricated spiral aments, the anthers 2-celled; pistillate fls. in spirally imbricated aments, 3-6 ovules under each scale, these aments becoming small globular cones with woody scales which are contracted at base and at apex incurved or acuminate or pointed.—Three species in Tasmania; by some considered to be inseparable from the genus *Cunninghamia*. These plants are little known in cult. Aside from seeds, cuttings may be used for prop.

**selaginoides**, Don (*A. alpina*, Van Houtte. *Cunninghamia selaginoides*, Zucc.). Stout, to 45 ft.: lvs. loose, lanceolate, incurved, acute,  $\frac{1}{2}$  in. or less long, those of young seedlings narrower: cones  $\frac{1}{2}$ - $\frac{3}{4}$  in. diam., the scales lanceolate-pointed. Mts.

**cupressoides**, Don (*A. imbricata*, Maule. *Cunninghamia cupressoides*, Zucc.). Tree, reaching 40 ft., with ascending branches: lvs. broad and obtuse, less than  $\frac{1}{6}$  in. long, thick and keeled, closely appressed to the branches: cones  $\frac{1}{2}$  in. or less diam., the scales rounded at top and bearing a short point.

**laxifolia**, Hook. (*A. Doniana*, Henk. & Hochst.). Tree, 25-30 ft., closely allied to *A. cupressoides*: lvs. imbricate but less appressed, acute, about  $\frac{1}{6}$  in. long: cones larger and scales more acuminate. Mts.

L. H. B.

**ATHÏRIUM**. A generic name recognized as valid by many well-known fern students. As usually delimited, it includes species of *Asplenium* (which see) which have some of the sori curved across the subtending veinlets. There are also differences in the stem structure. The species are mostly larger and more herbaceous than those of true *Asplenium*.

R. C. BENEDICT.

**ATRÁGENE:** *Clematis*.

**ATRAPHÁXIS** (ancient Greek name). *Polygonaceæ*. Ornamental shrubs grown chiefly for the white or pinkish flowers produced during the summer.

Low shrubs with spiny or unarmed branches: lvs. deciduous, short-petioled, alternate or fasciculate: fls. small, apetalous in few-fl. axillary clusters forming terminal racemes; sepals usually 5, sometimes 4, the 2 outer ones smaller and usually reflexed; stamens 8, sometimes 6; ovary superior with 2-3 styles free or connate at the base: fr. a small 2- or 3-angled achene enveloped by the enlarged inner sepals. Summer.—About 18 species in Cent. and W. Asia, Greece, and N. Afr.

These plants are of spreading habit, with usually small leaves, attractive with their numerous racemes of white or rose-colored flowers, which remain unchanged for a long time, owing to the persistent calyx.

They grow best in well-drained soil and sunny situations, but do not stand transplanting well when older. They are well adapted for planting in rockeries or on rocky slopes and are hardy North. The handsomest of the species is *A. Muschketovii*. Propagation is by seeds sown in spring; the seedlings are liable to rot if kept too moist, or in damp air. Increased also by greenwood cuttings under glass in early summer, and by layers. None of the species is in the American trade.

*A. buxifolia*, Jaub. & Spach (*Polygonum crispulum*, Sims). Height 1-2 ft., spineless: lvs. obovate, crenate, dark green,  $\frac{1}{2}$ -1 in. long: racemes short. Transcaucasia, Turkestan. B.M. 1065.—*A. frutescens*, Koch (*A. lanceolata*, Meisn.). Height 1-2 ft., spineless: lvs. ovate-lanceolate, glaucescent,  $\frac{1}{4}$ -1 in. long: racemes loose. Caucasus, Turkestan, Siberia. L.B.C. 5:489. B.R. 3:254.—*A. Muschketovii*, Krassn. (*A. latifolia*, Koehne. *Tragopyrum lanceolatum* var. *latifolium*, Regel). Erect, 2-3 ft., spineless: lvs. lanceolate, crenate,  $\frac{3}{4}$ -2 in. long: fls. white with the anthers and ovary red,  $\frac{1}{4}$  in. across in dense racemes. Turkestan. B.M. 7435. Gt. 40:1344.—*A. spinosa*, Linn. Height 1-2 ft., spiny: lvs. elliptic, entire, glaucescent,  $\frac{1}{4}$ - $\frac{1}{2}$  in. long: racemes short; sepals usually 4 and stamens 6. S. Russia, Orient, Siberia. ALFRED REHDER.

**ÁTRIPLEX** (from a Greek name of orache). *Chenopodiaceæ*. Herbs with inconspicuous flowers, some of which are used for forage under the name of salt-bushes, some for hedges or lawn specimens, and one as a garden vegetable, and many succulent weeds of desert regions.

Flowers diœcious or monœcious, in spicate or paniculate clusters, sometimes bunched in the axils: lvs. usually alternate or some opposite: fr. half or wholly inclosed by the persistent bractlets.—About 125 widely distributed species, often weeds. *A. patula*, in many forms, is a common weedy plant throughout the country.

*Atriplex hortensis* is a garden vegetable used like spinach; for culture, see *Orach*. *A. leptocarpa*, *A. semibaccata* and others have been introduced as supplementary forage plants for arid regions. *A. Breweri* is a popular low hedge plant in southern California.

A. Garden vegetable (with ornamental-lvd. variety).

**hortensis**, Linn. ORACH. SEA PURSLANE. Annual: st. herbaceous, erect: lvs. hastate, cordate, or triangular-oblong, acute, 4-5 in. long,  $2\frac{1}{2}$ -3 in. wide; petioles 12-18 lines long: fruiting bracts 4-8 lines long, short-pedicel. Var. *âtre-sanguinea*, Hort., is a crimson-lvd. ornamental about 4 ft. high, sometimes grown with amarantus-like plants. Old World. See *Orach*.

AA. Ornamental shrubs.

B. Shrubs 1-3 feet.

**canescens**, James. A pale, densely scurvy shrub, 1-3 ft. high: lvs. oblanceolate, entire: fruiting bractlets with 4 vertical, reticulated wings. July-Sept. New Mex. to S. Dak. and west to Calif.

**Hálimus**, Linn. Low-spreading shrub with gray foliage, cult. in Calif. for hedges and for seaside planting: lvs. 1-1 $\frac{1}{2}$  in. long; petioles 3-4 lines long: fls. purplish: fruiting bracts 1 $\frac{1}{2}$  lines long, 2 lines wide, sessile, reniform, obtuse, entire: seed compressed, yellowish. Medit. region and S. Afr.

435. *Atriplex Breweri*. Used for hedges in California. ( $\times \frac{1}{3}$ )

BB. Shrubs 4-10 feet.

**Bréweri**, S. Wats. Fig. 435. Stout woody shrub, 4-6 ft.: lvs. ovate-oblong, silvery gray, somewhat rhombic-cuneate at the base, obtuse and acute at apex, 1-3 in. long; fls. dioecious, the calyx deeply 4-cleft. At home in sandy, wind-swept places. S. Calif.

**lentifórmis**, S. Wats. (*Obidne lentifórmis*, Torr.). Diffusely branched, 4-10 ft., the branches terete, with rigid often spinescent branchlets: lvs. oblong-rhombic,  $\frac{1}{2}$ -1 $\frac{1}{2}$  in. long; fl.-clusters small, golden or silvery, the calyx 5-parted. S.W.U.S.—Silvery and tall, growing as the preceding but standing more cold.

N. TAYLOR.†

436. *Atropa Belladonna*  
or Deadly Nightshade.  
( $\times \frac{3}{8}$ )

**ÁTROPA** (after *Atropos*, that one of the three Fates who cut the thread of life). *Solanaceæ*. **BELLADONNA**. A genus of 2 species of Old World herbs of great economic importance. Calyx with 5 ovate leafy divisions, enlarging in fr.; corolla bell-shaped or funnellform. The purple berries are poisonous. The plant is used in medicine and is the source of atropine and other drugs. Not in cult. in U. S. except in botanic gardens.

**Belladónna**, Linn. Fig. 436. Plant erect, branching, leafy; lvs. ovate, entire, pointed; fls. single or in pairs, nodding on lateral peduncles; corolla blue-purple or often greenish purple. Eu. to India.

N. TAYLOR.†

**ATTALEA** (*attalus*, magnificent). *Palmaceæ*, tribe *Cocoinæ*. A large genus of horticulturally little-known palms, well worth more attention.

Stems spineless, single, usually ringed, sometimes lacking: lvs. usually many in a large erect tuft, pinnate, the numerous lfts. rather regularly placed, but at right

angles to the rachis, those above standing erect, those beneath falling below the rachis; young lvs. very attractive but rather stiff in their perfect erectness; petiole concave above, often very fibrous at the base: fls. monœcious or polygamo-dioecious, on a branched spadix inclosed in a rather woody spathe, at least at first, which appears among the lowest lvs.; spadix ultimately recurving, sessile, bracted, usually yellow: fr. a drupe, sometimes quite large, frequently fibrous-coated.—Because of their slow growth the 20-25 species are not very favorably known to the dealers. All are natives of Trop. Amer. See G.C. II. 22:523.

At least two of the species are of economic importance. *A. Cohune* is the source of a finer oil than that of the coconut, and is also used in making an intoxicating beverage. *A. funifera* is the source of a fine fiber much used in the making of brooms, and in rope-making.

Attaleas must be grown in a tropical greenhouse, with a night temperature not less than 60°. They will do best in a mixture of loam three parts, cow- or horse-manure, one part, and one part of sand.

Propagation is by seeds, which may be placed 2 inches deep in a box to be plunged out-of-doors in summer, covered with moss and watered freely.

A. Trunks becoming tall, or at least not stemless.

B. Bases of the petiole prominently fibrous: old lvs. persistent in *A. funifera*: trunks 18-30 ft.

**funifera**, Mart. **PISSABA PALM**. **COQUILLA**. St. 18-30 ft., 8-13 in. diam., smooth: lvs. as long as the caudex, green both sides; petioles with very long hanging fibers; segms. broadly linear-acuminate, in clusters of 3-5, divaricate, very numerous: drupe 4 in. long. Brazil.

**gomphococca**, Mart. St. 20-30 ft. crowned by a magnificent cluster of large (6-9 ft.) lvs.: lfts. very numerous, linear or linear-lanceolate, bright green above, paler beneath; petiole relatively short, very fibrous at the base: spathe slender and woody, the spadix reflexed, but short-stalked and half hidden by the lvs.: fr. fibrous-coated. Costa Rica.—Intro. by Reasoner Bros. in 1911.

BB. Bases of the petiole not prominently fibrous: trunks 50-100 ft.

**excelsa**, Mart. St. 90-100 ft. high in the wild, 16-20 in. diam.: lvs. erect-spreading; pistillate fls. solitary on the branches of the spadix: drupe oblong-cylindric, acute at both ends. Brazil.—A little-known palm among the dealers, but not uncommon in fanciers' collections. Stately in habit and with splendid large lvs.

**Cohune**, Mart. **COHUNE PALM**. Fig. 437. St. 50-60 ft.: lvs. erect, pinnate, the dark green pinnæ 30-50 and 18 in. or less long; petiole flat above and rounded below: drupe broadly ovate, nearly 3 in. long, with a very short beak. Honduras.—Fruit used for soap-making, and exported from Cent. Amer. for that purpose. Used for thatching.

AA. Without trunks.

**spectabilis**, Mart. Stemless, or with a very short caudex: lvs. 18-21 ft. long, erect or spreading, the lower segms. 3-4 ft., the upper 12-16 in.,  $\frac{1}{2}$  in. wide, linear-acuminate: spathe erect: fr. about as large as a hen's egg. Brazil.—Requires plenty of water, as its home is on the banks of the Amazon.

**amygdalina**, HBK. (*A. nucifera*, Karsten). Stemless: lvs. 15-18 ft. long, crowded, pinnatisect; segms. 90-100 on each side, ensiform, glabrous above, with hairs along the outer margins beneath,  $2\frac{1}{3}$ -2 $\frac{2}{3}$  ft. long, about  $1\frac{1}{4}$  in. wide; petiole with rusty scales beneath: spadix of male fls. about 18 in. long, with a flattened stalk, inclosed by a thick woody spathe. Brazil.

*A. Guichire* is a trade name; "extremely long-leaved."—*A. Maripa*, Mart. (*A. Mariposa*, Hort.). See Maximiliana.

N. TAYLOR.†

**AUBRIETIA** (Claude Aubriet, French natural history painter of last century). *Cruciferae*. **PURPLE ROCK-CRESS**. Showy perennial more or less evergreen trailers, excellent for rockwork or edgings.

Allied to *Alyssum* and *Vesicaria*: distinguished chiefly by the outer sepals being saccate at base, the shorter filaments toothed, and the valves of the oblong or globose silique convex and not ribbed: lvs. entire or angular-toothed: fls. in shades of violet or purple, in few-fl'd. bractless racemes: plant canescent or tomentose.—About a half-dozen species, Italy to Persia. The aubrietias are of simple cult. Prop. by seeds, layers or cuttings. They make excellent mats of foliage and bloom.

**deltoides**, DC. Fig. 438. Lvs. oblong-spatulate, deltoid or rhomboid, with 1 or 2 teeth on either side, grayish, narrowed into a very short petiole: fls. in few-fl'd. lax clusters, the violet or purple petals twice the length of the calyx.—Grows 2–12 in. high. Pretty spring and summer bloomer. Hardy in the N. Very variable, some of the forms being named as if of specific rank. Var. *Bougainvillei*, Hort. Fls. light violet: dwarf and compact. Var. *Campbellii*, Hort. Fls. large, purple: plant large. Var. *Eyrei*, Hort. Fls. large and long, deep violet. Var. *græca*, Hort. (var. *superba*). Dwarf and compact, large-fl'd. One of the best. Var. *Hendersonii*, Hort., probably the same as *Campbellii*. Var. *Leichtlinii*, Hort. Profuse bloomer, pink fls. Var. *olympica*, Hort. Fls. large, violet, like var. *Eyrei*. Var. *violacea*, Hort. One of the largest forms. Var. *Mooreana*, Hort. Compact: fls. blue. Var. *Perkinsii*, Hort. Fls. deep purple with tiny white eye, the petals rounded: plant strong, 10 in., making a large mat. Gn. 67, p. 344. Raised by F. Perkins, Stratford-on-Avon. Var. *Moerheimii*, Lemoine. Fls. large, rosy pink or mauve, blooming all summer. Var. *purpurea*, Hort. Erect in habit: fls. large, purple. Var. *variegata*, Hort. Lvs. variegated.

L. H. B.

**AUCUBA** (Latinized for *Aokiba*, its Japanese name). *Cornaceæ*. Ornamental plants grown for their large evergreen foliage, often handsomely variegated, and also for the bright scarlet fruits.

Shrubs with stout forked branches: lvs. opposite, remotely serrate or nearly entire: fls. dioecious, small; calyx minute, 4-toothed; petals 4; staminate fls. with 4 stamens, filaments short, with a large disk in the middle; pistillate with an inferior 1-celled ovary, style short with an oblique stigma: fr. a 1-seeded berry-like drupe.—Three species in E. Asia extending west to W. China and E. Himalayas, often considered varieties of one polymorphous species.

The aucubas are evergreens with large, lustrous, and often handsomely variegated leaves, small purple flowers in terminal panicles, elongated in the staminate, short and rather dense in the pistillate plant and with bright scarlet oblong berries forming terminal clusters. Hardy in the southern states about as far north as Washington, D. C., and in sheltered localities even farther north; they are well adapted for city gar-

dens as they withstand dust and smoke to a considerable degree.

In the northern states, aucubas are grown in cool-houses—those adapted to azaleas are excellent—and they are kept evergreen by keeping them in a pit during winter, or by holding them cool and partially dry

in the house. They will stand five or six degrees of frost in a pit. From cuttings of half-ripened wood, good specimen plants may be had in two or three years. Fruiting plants, with their numerous bright scarlet berries, are exceedingly attractive, but as the plant is dioecious, there must be male plants with the female ones. If grown in pots and under glass, the plant must be fertilized by shaking the flowering male plant over the female, or by applying the pollen with a camel's-hair pencil. If the male plant flowers earlier, the pollen may be collected and kept dry until the female plant is in flower; it remains effective for some weeks. In the open, aucuba

grows well in any good, somewhat moist though well-drained soil, in a half-shaded position. In pots, it will thrive in a sandy loam with sufficient drainage, and requires plenty of water during its growing period. Fruiting plants should not have too large pots.

They are propagated very easily by half-ripened greenwood cuttings at nearly any time of the year, under glass, and by seeds sown soon after maturity; the varieties are sometimes grafted on the common form in early spring, under glass.

**japonica**, Thunb. A stout shrub, 4–15 ft.: lvs. usually ovate, 3–8 in. long, remotely and coarsely dentate, obtusely acuminate, shining: petals obtusely acuminate: berries scarlet, rarely white or yellow, usually oblong. From Himalayas to Japan. B.M. 5512. I.H. 11:399. S.I.F. 2:59. F.S. 16:1609. F. 1865:65.—There are a great number of garden forms in cultivation, mostly with variegated leaves; the latter are more often cult. than the green forms. Handsome variegated forms are: Var. *latimaculata*, Kirchn. (var. *aureo-maculata*, Dombrain). Lvs. ovate-oblong with a large irregular yellow blotch in the middle and smaller yellow dots around it. F.M. 10:527. F.W. 1876:353. Var. *variegata*, Dombrain, not Regel (var. *maculata*, Regel, var. *picata*, Hort., var. *punctata*, Hort.). **GOLD DUST TREE**. Fig. 439. Lvs. with numerous yellow spots.—The most commonly cult. form. B.M. 1197. F.M. 5:277. R.H. 1866:292. Var. *limbata*, Bull. Lvs. large, coarsely dentate, with a greenish yellow margin. Var. *bicolor*, Regel. Lvs. with a large yellow blotch in the middle, ovate to ovate-oblong, remotely dentate. The following forms have green lvs.: Var. *angustifolia*, Regel (var. *salicifolia*, Hort.). Lvs. narrowly oblong-lanceolate. Var. *concolor*, Regel (var. *viridis*, Hort.). Lvs. ovate-lanceolate or elliptic-ovate, remotely and coarsely serrate. Gt. 25:859.

Var. *dentata*, Carr. (var. *macrodonata*, Hort.). Lvs. elliptic, coarsely and long-dentate. Var. *macrophylla*, Bull. Lvs. large and broad, remotely and slightly dentate. Var. *ovata*, Regel. Lvs. ovate, coarsely sinuately dentate, dark green, lustrous. Var. *pygmaea*, Regel. Low: lvs. ovate-oblong, remotely and sharply

438. *Aubrietia deltoidea*. (plant  $\times \frac{1}{2}$ )

437. *Attalea Coghne*.

dentate, bright green, dull. Differently colored frs. distinguish the following forms: Var. *luteocarpa*, Rehd. (*A. luteo-carpa*, Dombrain) with yellow fr. F.M. 1872: 12. Var. *leucocarpa*, Matsum. & Nakai, with white fr.—*A. cranifolia*, once offered in American trade, is probably a form of *A. japonica*. To indicate whether a certain form is a staminate or a fruit-bearing plant, mascula or femina (fœmina) is often added to the varietal name.

*A. chinensis*, Benth. Lvs. lanceolate to nearly obovate, entire or toward the apex sharply dentate, sharply acuminate; petals finely and long-acuminate; panicle with scattered short and stiff hairs. China.—*A. himalaica*, Hook. f. & Thoms. (*A. japonica* var. *himalaica*, Dipp.). Lvs. usually lanceolate to ovate-lanceolate, entire or dentate, sharply and long-acuminate; panicles densely hairy; petals long and finely acuminate; fr. orange to scarlet. E. Himalayas. F.S. 12:1271. L.H. 6:197. ALFRED REHDER.

**AUDIBÉRTIA** (*M. Audibert*, of Provence). *Labiatae*. Including *Ramona*. Perennial herbs or sub-shrubs, sometimes grown for bees and in ornamental plantings.

Ten species all from W. U. S. mostly from Calif., related to *Salvia*, but differing in the calyx being more deeply cleft in front, and in being almost spathaceous: lvs. opposite, usually rugose, sage-like: fls. axillary or terminal, not unlike those of *Salvia officinalis*; corolla with upper lip spreading, 2-lobed or emarginate.

**grandiflora**, Benth. St. villous, glandular, 1-3 ft. high: lvs. woolly beneath; lower lvs. hastate, obtuse, 3-8 in. long, coarse; bracts crowded, conspicuous: fls. 1-1½ in. long, red or crimson-purple, in dense, showy clusters. Calif.—Prized for bees.

**incana**, Benth. St. woody, tomentose-canescens, leafy: lvs. spatulate or obovate, obtuse or retuse, not rugose, scarcely 1 in. long; bracts obovate, ciliate, purple-tinged; corolla ½ in. long, rarely slightly longer, pale blue. Wash. to Ariz. B.R. 1469. N. TAYLOR.

**AURÍCULA** (*Primula Auricula*, Linn.). Fig. 440. A European perennial, sending up short scapes, bearing flowers of many colors. It is one of the most famous of florists' flowers, but it has never received the attention in this country that it has in Europe. Our summers are generally too hot for it. In this country generally treated as a greenhouse plant; but it is hardy, and in the Old World is grown largely in frames. See *Primula*.

Auriculas grow wild in the mountainous districts of Switzerland, Austria, Syria, and the Caucasus; therefore they are generally regarded as alpine plants, but like many other alpine, they have proved to be excellent subjects for cool greenhouse culture as well as for rock- or alpine-garden culture. In their native habitats, some plants are heavily powdered with a fine mealy substance called "farina," while others are perfectly destitute of it. Under cultivation, also, they show this same characteristic. This has caused fanciers to divide them into two sections; those covered with farina, called show auriculas, and those destitute of it, termed alpine auriculas. The show auriculas have received the most attention at the hands of fanciers. Their flowers are large, and present more combinations in variety of color than the alpine section, and since rains mar their beautiful farina-covered leaves and flowers, they are by far best adapted to greenhouse culture. Like all primulas, the flowers are tubular and borne in erect trusses well above the foliage. Well-grown plants will produce strong trusses with often as many as twenty "pips" or individual flowers. Such a number cannot fully develop, consequently they should be thinned out

and only eight or nine flowers allowed to develop on each truss. The tube of the flowers of show auriculas is usually white, with a circle of maroon, violet, plum or chocolate-color above and a margin of green, gray, white, or yellow. In what are called "selfs," the circle of chocolate-maroon, or violet, extends to the edges of the flowers. They are usually very sweet-scented. Alpine auriculas are best adapted for growing in the rock- or alpine-garden since the leaves and flowers are destitute of farina. This section does not exhibit as large a variety of color in the flowers. The tube of the corolla is usually

yellow or cream-color with a margin of maroon or purple which shades off toward the edges. The culture given below is the same for both sections except that the alpine section should be planted on the north side of the rock-garden in October, where they will flower the following spring.

Auriculas may be propagated by seed for general purposes and for the production of new varieties, but to perpetuate very choice varieties it is necessary to propagate either by offsets or division of the plants. Seed should be sown in shallow pans or 4-inch pots early in March, so

that the seedlings will be well developed before very warm weather sets in. The soil used in the seed-pans should be very light and sandy, the surface should be made smooth, and the seeds then pressed lightly

into the soil, after which a light covering of sand should be given, and the pans placed in a temperature of 60° until they have germinated, which usually takes from three to four weeks; pans should then be removed to a light position, shaded from direct sunlight, in a rather lower temperature, to induce a stocky growth. As soon as the seedlings are large enough to handle conveniently, they should be pricked off into other pans or shallow boxes containing a mixture of three parts leaf-mold and one part sifted loam and clean silver-sand. Watering should be carefully attended to, and everything done to promote active growth, so that, if possible, the plants may be large enough to require a second shift into other boxes, similarly prepared, by the end of June. Auricula seedlings go through the hottest months much better in boxes than in pots, as they can be kept more evenly moist. For their summer quarters, a wooden frame placed on sifted coal-ashes on the north side of a building or wall, or almost any position in which they will be sheltered from the sun and still receive plenty of light, should be given them. The frame should be provided with sash, which should be kept over the plants most of the time, giving air in abundance in favorable weather, and during the warmest weather the whole frame should be raised by placing a brick under each corner, so as to allow a good circulation of air among the plants. About the second week in September the young plants should be potted, using a compost of two parts good fibrous loam, one part leaf-mold, and one part well decayed cow- or sheep-manure, with a little sand added. The frame should be kept a little close for a few days after potting, and from this time care must be taken not to wet the foliage in watering. The plants may remain in the frame until danger of freezing, when they should be transferred to a cool

439. *Aucuba japonica* var. *variegata*. (×½)

greenhouse for the winter. All decaying leaves should be carefully removed, and but little water will be required during the dull winter months. Toward the end of February the plants will show signs of flowering, when they should be given a top-dressing of pulverized sheep-manure and placed in a light, airy position, in a temperature of 55°. The flowering season lasts about two months, after which the plants should receive their annual potting. All diseased or decayed roots should be cut away, and most of the old soil carefully removed. The propagation of very choice varieties by offsets or division is best done at this time. The pots used in potting should be well drained, and no larger than will just accommodate the plants. The soil best suited is the same as before recommended. After potting, they may be placed in their summer quarters. Offsets should be inserted around the edge of 4-inch pots, using very sandy soil, and kept in a moist, shaded position until rooted. By annually repotting and giving a little extra care during the summer months, a batch of show auriculas will return very satisfactory results, and may be kept in a good, healthy condition for several years.

EDWARD J. CANNING.

#### AUTUMN COLORS, PHYSIOLOGY OF.

When the conditions in almost any locality are favorable for the rapid growth of plants, the prevailing color of the vegetation is green. The leaf-green, or chlorophyll, is a conspicuous part of vegetative organs. Green is normal, so that one does not regard a green plant as "colored." It is true that in some species of plants, chlorophyll is partially or completely veiled by the presence of other pigments, and in the blossoms it may practically fail; but in the latter case the life of the brilliant structures is fleeting, and green is promptly predominant. "Color" is more or less restricted to blossoms, to particular species, or to seasons. The great seasonal change is here the center of interest.

In the autumn the vegetation of the usual temperate landscape loses gradually its distinctive green, while striking yellows and reds are substituted. With favorable conditions, the climax of this transformation is such a riot of color as is not seen at any other time. It is noteworthy that this change is an immediate forerunner of leaf-fall and death. The vegetation that is suddenly cut off by severe frost seldom exhibits true autumnal colors, but instead the dry brown or blackened effects of rapid death, characteristic of any season. On the other hand, autumn tints of leaves may appear in the summer, as when limbs of the hard maple or peach are ringed. This suggests that the production of color is susceptible of experimental study. On the whole, the layman may regard the autumn colors as a necessity to the wholesome rounding out, and a fitting terminus, of a season of usefulness. Coloration is, however, an evidence of fundamental physiological changes; and it is appropriate to ask regarding the climatic or other conditions which bring this about, as well as concerning the nature of these internal changes which also make for the development of color in the autumn.

For the most part, the autumn leaf-colors fall into two groups—yellows and reds. These colors are pro-

duced by two groups of pigments essentially different in chemical and physical properties; yet these pigments are frequently blended in the same leaf, yielding such gorgeous effects as may be seen in the sumach.

The yellow pigment (more correctly pigments) of leaves occurs in the chlorophyll bodies of the cell. It is present in conjunction with the leaf-green in the healthy leaf, but not infrequently it seems to increase in quantity as the chlorophyll disappears. It belongs to a group of substances often called xanthophylls. These are carotin-like compounds, that is, related to carotin, the orange or orange-red pigment of the carrot root. Carotin-like bodies are widely distributed in plants and are also responsible for the yellow, orange, and orange-red colors of a large number of blossoms. These pigments do not occur in solution in the cell-sap, but may be present either in the healthy chlorophyll bodies (plastids) or outside of them. In the latter case, they form crystals, or are in solution in droplets of fatty oils. Carotin-like compounds are more permanent than chlorophyll, so that any green plant may exhibit a yellowish color upon the gradual disappearance of the chlorophyll.

The red pigments of autumn leaves are cell-sap colors, substances soluble in the aqueous solution constituting plant juices. They are supposed to be tannoid compounds, and are generally referred to as anthocyanin. The pigments of red beets and dark grapes are similar compounds. It is significant that those plants exhibiting conspicuous red coloration in the autumn are usually those which give some indication of red during the growing season, as in the possession of red petioles or twigs; and, more especially, they are those in which red is more or less conspicuous as the buds open and the leaves unfold in the spring. The attractive tints of unfolding hard maple buds are therefore an indication that the maple has the capacity to develop a coloration of the cell-sap in the autumn. Some plants develop no anthocyanin under normal conditions of growth.

It is then evident that the yellow colors of autumn leaves may be due to both a greater visibility of the yellow in the chlorophyll body when the chlorophyll disappears, and also to actual increased development of carotin-like compounds. The reds and purples in autumn leaves are a result of the formation or increased formation of tannoid compounds. The question then is: What are the conditions which make the autumn season particularly favorable for the development of these substances?

Some careful studies have been made that bear upon this question. It appears that the production of autumnal reds in many species is related to the sugar-content, and color may be induced or heightened in the shoots of many plants by growing them for a time in strong solutions. Moreover, cold weather has been found to be generally favorable to the accumulation of sugar in the tissues. Observation indicates that after a season favorable for growth, a cold, protracted autumn results in exquisite autumn coloration. It is certain that nothing is more disastrous to brilliance of color than severe early frosts. In addition to enhancing pigmentation, sugar-content seems to be most important as one factor in cold-resistance. It requires a very light frost in the late summer to kill outright the leaves and young shoots of many trees, but the same shoots may be unaffected by an equal degree of cold when the conditions have been such as to bring about the normal autumn coloration.

B. M. DUGGAR.

**AUTUMN-GARDENING.** There is wealth of material for spring- and summer-gardening; but to secure good garden effects in autumn requires mostly other material and a different intellectual conception of the problem. The common problems of the gardener in autumn grow out of two facts: First, the frost kills tender plants sooner than he desires; therefore he tries

440. Auricula. ( $\times \frac{1}{2}$ )

to save vegetables and flowers as long as possible by protection and by choosing hardy kinds. Second, gardens tend to look unattractive and seedy in September, because this is nature's time for ripening fruits; therefore he desires fresh flowers. The popular demand is for fresh vegetables as long as possible, color in the garden right into the teeth of winter, cut-flowers after frost, home grounds that will be attractive even after a summer's absence, and a note of welcome to the children in every school-yard. Also, there are enthusiasts who wish gardens devoted exclusively to autumn beauties.

#### *Prolonging the vegetable-garden.*

The ideal way to prolong the yield of fresh vegetables in late autumn is by means of greenhouse, hotbeds and coldframes. In frames, which are the cheapest, it is

441. A good autumn landscape for color effects.

easy to have in November lettuce, spinach and radishes. The next best plan is to shelter the garden from cutting winds and frost by a windbreak, e.g., wall, fence, hedge, natural wood, or group of evergreens. Sheltered gardens often yield fresh vegetables two to six weeks after adjacent unsheltered gardens have been devastated by frost. It is also possible to prolong the season by raising late-growing varieties and by starting the ordinary kinds later in the year.

#### *Freshening the flower-garden.*

Parks and the grounds of wealthy people often rely chiefly on tender or temporary bedding plants, e.g., cannas, dahlias, scarlet sage, gladioli, geraniums and Pfitzer's torch-lily, for their largest masses of autumn color. This method gives the greatest show the first year, but is costly in the long run. Moreover, these plants are killed by frost, leaving gaps too large to fill.

A grade higher is hardy bedding, which has become popular since 1900. The favorite plants are long-blooming shrubs and perennials, e.g., Baby Rambler rose, garden and tree hydrangeas, Miss Lingard phlox, gaillardias, stokesia, Napoleon III pink, double ragged

robin, *Veronica longifolia* var. *subsessilis*, *Conoclinium* (*Eupatorium*) *celestinum*.

Unfortunately, the flowers of the two preceding lists do not really freshen the garden, because they are summer flowers or are being made so by the irresistible tendency to exploit earlier varieties of everything. As taste improves, there is a reaction against excessive use of long-blooming plants, and a desire has arisen for "season markers." Among the finer plants of this real autumn sort are *Colchicum Parkinsonii*, *Crocus zonatus*, *C. speciosus*, *C. sativus*, *Crinum Powellii*, *Sternbergia lutea*, *Chrysanthemum uliginosum*, gordonia, and the rarer plants to be mentioned hereafter. They are, however, plants of the skilled amateur.

For beginners, the favorite hardy autumn flowers include the following annuals or plants treated as such, —China asters, pansies (sown outdoors about May 10 in latitude of New York City), snapdragons, and cosmos; bulbs, —*Colchicum autumnale*; perennials, —sneezeweed, *Helianthus orgyalis* and *H. Maximilianii*, and pompon chrysanthemums.

Another way of providing fresh color in autumn is to make a second or June sowing of favorite annual flowers, e.g., sweet alyssum, candytuft, love-in-a-mist, common and pot-marigold, mignonette, nasturtium, phlox, California poppy, portulaca and zinnia. These usually fail in September from the April sowing. The June sowing will carry them beyond a hard frost, except nasturtium and portulaca.

#### *Flowers after frost.*

In early November, after frost had devastated the gardens in the neighborhood of Philadelphia, the following flowers were in condition at one of the largest nurseries of perennials. Only those are mentioned that gave decided masses, not mere dots or remnants of color: *Aconitum columbianum*, *A. Fischeri*, alyssum, antirrhinum, *Aster grandiflorus*, *A. tataricus*, *Cimicifuga simplex*, Napoleon III dianthus, *Erigeron glabellus*, gaillardias, gladioli, *Helianthus Maximilianii*, huneemannia, kniphofias, pansies (sown in May), Miss Lingard phlox.

Nearly all the flowers in the two preceding lists are available for home decoration, although the quality may not be equal to that of early September. If long-stemmed, long-lasting flowers are needed in quantity, the most satisfactory, perhaps, are chrysanthemums, snapdragons, Miss Lingard phlox, gaillardias. To this list may be added delphiniums, Baby Rambler rose and *Catananche cærulea*.

#### *Gardens based on the dominant color.*

It is feasible to make a garden that changes its color every three or four weeks, based upon the idea that a garden may well reflect the dominant color in the landscape produced by the wild flowers of each season. Since yellow is the dominant color of autumn (witness the goldenrods, sunflowers and other composites) such gardens may be rich in sneezeweed and perennial sunflowers (especially *Helianthus Maximilianii*, *H. orgyalis*, and *H. multiflorus* var. *plenus*) since these are particularly appropriate to season and country. The following yellow flowers of summer may be prolonged into autumn by seed-picking, cutting back, fertilizing, and watering: Tufted pansies, snapdragons, Golden Glow rudbeckia, gaillardia, Iceland and horned poppies, *Anthemis tinctoria* and *Lepachys columnaris*.

#### *Gardens of perennial asters.*

The English make an exceedingly showy, yet artistic, garden based upon what they call "Michælmass daisies" (asters), of which 137 species and varieties are catalogued by a single dealer. It consists of a double border devoted to the early kinds that bloom during the first three weeks of September; and a separate border for the October- and November-blooming species.

The pictorial effect is improved by a definite color scheme, planting in drifts, and an ingenious system of training on hidden branches. This type of garden is of peculiar interest to Americans because the perennial asters are mostly American wild flowers, and it meets the general desire to grow a class of flowers which is too prolific for the ordinary garden. Owing to the notorious difficulties of identifying species of this genus, Americans find it more practicable to import collections than to assemble species from the wild. The true asters are generally supplemented by yellow flowers of other genera (e.g., *Chrysopsis*) in order to make the early garden a pink and yellow composition, while the later garden is devoted to purple, lavender and blue.

#### Woody plants for autumn bloom.

In larger gardens and on home grounds it is desirable to secure flowers by using more permanent materials, as woody plants. Unfortunately, the only tree that blooms in autumn (*gordonia*) has to be wrapped during winter in the North. The list of vines also is small, being confined to left-over blooms of trumpet creeper, Hall's honeysuckle, and panicked clematis.

The autumn-blooming shrubs, however, are excellent. Unluckily, the showiest of them all, *Hydrangea paniculata* var. *grandiflora*, is commonly used in such ways as to bring upon American yards the reproach of gaudiness and vulgarity. It looks gross and overfed compared with the slender grace of its prototype, *H. paniculata*, and its double flowers are artificial compared with the single ones. True, they last longer and give more for the money than any other flower of autumn, but such plants from their irresistible appeal to beginners, are planted in every yard and tend to make home grounds look too much alike and too common. The situation is aggravated by inartistic ways of using it, e.g., hedges from sidewalk to porch, great masses across the front of the house, borders of curving drives, and beds in the middle of the lawn. Again, it is pruned severely to make the largest trusses, which results in loss of height and dignity, and in top-heavy masses ill-concealed by supports. A better system of yard-decoration, is the use of informal shrubby borders, since they give year-round interest and greater variety to yards.

To supplement the ubiquitous double hydrangea, the following may be recommended, subject to the limitations noted: *Abelia chinensis*, white, begins blooming in Georgia in June and is well covered in New England as late as September 30; *Abelia grandiflora*, pink, needs a winter covering of boughs North; *Baccharis halimifolia*, has tufts of showy pappus, like camel's-hair brushes, that look like white flowers; *Buddleia variabilis*, pink, is killed to the ground at New York but recovers and blooms freely; *Caryopteris Mastacanthus*, blue, behaves like buddleia; *Hamamelis virginiana*, yellow, not showy, but the last shrub to bloom; *Hibiscus syriacus* or althæa (only the single white variety here recommended); *Hydrangea paniculata* var. *laxa*, which gives a fresh white after the double hydrangea has begun to assume its metallic colors; roses, hybrid teas, which are at their best on Long Island in early September; *Vitex Agnus-Castus*, lilac, hardy to New York.

#### A more artistic way of securing color.

Although the popular interest is in flowers, there is a far more important method of securing color,—by means of trees, shrubs and vines with brilliant autumn colors in foliage and fruit. This method is more artistic because more appropriate to the season, more permanent, and cheaper in the end. It is also more American, because we have more native shrubs than autumn flowers; because shrubbery is the only class of material (except water-lilies) in which we enjoy a climatic advantage over England; and because autumnal colors in America are more brilliant than those in western Europe.

For home decoration, cut sprays of multiflora rose, common barberry, bittersweet, and the like, are longer-stemmed and last longer than flowers. Those just named remain attractive all winter, even when shriveled.

Our climate naturally suggests flowers in spring, attractive foliage in summer, natural colors in autumn, and in winter the shrubs with brightly colored berries and twigs. The late season situation can be met by making 90 per cent of the planting consist of combinations of trees and shrubs with triple or quadruple attractions of flowers, foliage, autumn colors and fruit, e.g., *Cornus alba* and var. *sibirica*, *C. Amomum*, *C. florida*, and *C. mas*; *Viburnum cassinoides*, *V. Lentago*, *V. prunifolium*, *V. Lantana*, *V. tomentosum*, and *V. americanum*; *Magnolia stellata*, *M. Soulangeana*, *M. glauca*, *M. acuminata*, and *M. tripetala*; *Berberis vulgaris* and *B. Thunbergii*; Regel's privet and the best form of the Amoor River privet; Morrow's bush honeysuckle; prairie, multiflora, rugosa, and Wichuraiana roses and their sturdiest descendants; and the following vines: *Euonymus radicans* var. *vegetus*, trumpet creeper, wistaria, bittersweet, and the wild and panicked clematis.

442. An autumn-blooming bulb.—*Colchicum autumnale*.

#### Color harmony in autumn.

Sentimentalists aver that nature never produces discordant colors, although the famous poinciana of the tropics and the nemesias of the garden furnish a combination of magenta and scarlet in the same flower. A walk through a good arboretum in September will convince the unprejudiced observer that discords exist in flowers, fruit, and foliage. In practice, nine-tenths of the troublesome discords are produced by the magenta group of colors, including the strongest purples, crimson, lilac, and crimson-pink. The artistic way to handle these colors is to isolate them in nooks surrounded by green, or to put them in deep shade, where they are purified and softened, instead of allowing them in the open garden, where full sun makes them too strong and where they conflict with all other colors, except white and green. The list of "dangerous colors" includes the flowers of Japanese anemone, crimson-pink chrysanthemums and China asters (in all of which safer colors are available), the Anthony Waterer spirea, the subsease veronica, *Lespedeza Sieboldii* and *Clerodendron fatidum*. Examples among fruits are Indian currant, callicarpa, burning-bush, strawberry-bush and several of the species of euonymus during the period when their highly colored capsules conflict with their scarlet arils. The purplish-twigged shrubs, e. g., *Cornus alba*, *C. Amomum*, *C. stolonifera*, and *C. Purpusii* (the last a species commonly but unwittingly distributed as *C. Amomum*), constitute an exception, since they are brilliant only in sunlight, and their color being dis-

sipated, instead of massed, is less liable to produce discords.

In foliage, the colors bordering on magenta are so rare that they may be ignored in planning the home-grounds, although careful designers always consider autumnal colors. When discords occur they may be resolved usually by planting between the discordant trees or shrubs some plants that retain green foliage until late autumn. Wine- or claret-colored foliage, like that of the maple-leaved arrow-wood, or crimson, like that of *Itea virginica*, occasionally makes discords with nearby foliage of yellow or scarlet, but in the case of such small plants it is usually easier to remove one of the trouble-makers. The sweet-gum, however, often makes a large mass of very dark purple, which may seriously disagree with yellow-foliaged specimens, or with buildings of yellow or red, especially since it has come to be used as a street tree. In practice, however, flowers make less trouble than shrubs, and shrubs than trees, and discords may generally be abolished by moving the smaller plants. The commonest and greatest color difficulty in autumn foliage comes from over-planting the following class.

443. Hardy chrysanthemum, one of the best of the autumn-blooming herbaceous plants.

Scarlet foliage in autumn theoretically may be no more vivid than other colors, but it is popularly regarded as the climax of all the autumn colors. For example, persons who give little thought to planting for autumn effect buy the scarlet and Tartarian maples, the red variety of silver maple, and ask the nurserymen for "a sugar maple that is guaranteed to turn red." The aromatic, scarlet, smooth, and staghorn sumachs are in considerable demand.

And, above all, the Japanese and common barberry are planted. At the entrance to public parks are often seen several hundred Japanese barberries planted in a bed for a blaze of autumn color. If disproportionately large, such masses of scarlet are perhaps only one grade higher than tender foliage plants. The brilliant reds commonly conflict with brick buildings and partico-colored houses of wood.

Deep red foliage in autumn is quieter, but rich enough. It is seen in the scarlet, pin, and red oaks, flowering dogwood, black choke-cherry, wild gooseberry (*Ribes cynosbati*), and several native huckleberries and roses.

Bronze foliage is seen in most of the plants that become red, for they attain to it from green through many bronzy colors. But the richest bronzes generally are associated with thick, lustrous, persistent leaves. The most highly esteemed, because most costly, are the broad-leaved evergreens, e.g., the Hinodigiri and amœna azaleas, mahonias, leucothœs, *Pieris floribunda* and *P. japonica*, and galax. These assume their brightest colors in full sunshine and, at the northern limits of their cultivation, sometimes suffer a loss of foliage. In the higher latitudes it is often best to sacrifice color to hardiness, by sheltering the plants from winter winds and sunshine, in which case they usually retain a lively green. A cheaper list, because composed of semi-evergreen plants, comprises California privet, Hall's honeysuckle, Wichuraiana rose, sweet fern, and bayberry. These color poorly in some localities, but they are of special value in the latter half of Novem-

ber, when the landscape first becomes bare, except for evergreen and nearly evergreen plants.

Yellow and orange foliage in autumn is midway between the vividder and the quieter autumn colors, the former having an exciting, while the latter have a soothing, effect upon the mind. The yellow and orange group rises in vividness from pale yellow, through gold to orange, the three stages being exemplified by larch, witch-hazel, and persimmon. Here belong the striped maple, yellow-wood, Kentucky coffee tree, ironwood, *Prunus pennsylvanica* and *P. serotina*, cucumber tree, large-leaved magnolia, *Crataegus punctata*, yellow-root and sugar maple. The duller yellows merge with the next group.

Brown and neutral autumn foliage tones down the most brilliant colors and resolves nature's discords. Examples are the American and slippery elms, and perhaps even the brighter red and chestnut oaks.

Green foliage in autumn is even more valuable in harmonizing colors. It is well expressed in the evergreens and nearly evergreen plants. The sudden devastation of the landscape occasioned by the fall of the leaves (whence the Americanism "fall" as a synonym of autumn) excites fresh interest in all the plants that remain green. These are of three classes: (1) The broad-leaved evergreens constitute the most sumptuous class of hardy plants, because they often possess showy flowers or fruits in addition to broader and more lustrous leaves than the conifers. Of the fifty kinds that are hardy in the latitude of New York, the following have special autumn attractions: *Osmanthus Aquifolium* (flowers), mountain laurel (red twigs), American holly, climbing euonymus, fire thorn, *Cotoneaster buxifolia* and *C. microphylla*, partridge berry, and wintergreen. In the South, the following have special attractions in autumn: English holly, *Euonymus japonicus*, ardisia, and nandina, all of which have red fruits, and pernettyas having fruits of various colors. Unfortunately, no plant of this class much exceeds 15 feet in height in the northeastern United States, and it is idle to hope for a 50-foot tree of this group, such as England possesses in the holm oak or ilex. (2) The narrow-leaved evergreens, or conifers, may lack showy flowers but they furnish more tall hardy plants than the broad-leaved evergreens. Their year-round uses are too numerous for mention here, but their autumnal functions are four,—(a) to harmonize discords; (b) to rest the eye from color; (c) to furnish contrast, which intensifies color; (d) to give greater dignity than showy colors possess. This dignity is due to the year-round beauty, longer life, and costliness of white and red pine, northern and Carolina hemlock, Nordmann and concolor fir, white and Douglas spruce, red cedar and arborvitæ, as compared with cheap, showy and temporary deciduous trees like willows, poplars, silver maples, and the like. Even the Vermont sugar-bush which, in October, is one of the most gorgeous spectacles, presents a finer appearance in the landscape when skirted by occasional white pines, which add greatly to the dignity and "paintable quality" without obscuring its farm value or purposeful character. (3) The nearly evergreen or half-evergreen plants may be bare from one to three months, depending largely on latitude and season. The plants that remain green until their leaves fall are mostly natives to western Europe, or to the warmer parts of China, Japan or Korea, and are usually associated with a moist and cloudy autumn. European examples are buckthorn, common privet, sea buckthorn, *Cytisus capitatus* and *C. nigricans*, *Genista tinctoria*, *G. elata*, *G. pilosa* and *G. germanica*. Far-eastern examples are California privet, matrimony vine, panicle clematis, *Akebia quinata* and *A. lobata*, *Lonicera fragrantissima* and *L. Standishii*, and *Euonymus Hamiltonianus* var. *semipersistens*. American examples are few, and *Lonicera Ledebourti* comes from California (climate like Europe), but the overcup oak and *Leucothœ racemosa*

are eastern and southern plants. All these species were reported as being green at the Arnold Arboretum as late as November 8. The peculiar value of this class is as a substitute for broad-leaved evergreens. Unfortunately, the climate of the northeastern United States is not favorable to broad-leaved evergreens, compared with the South or Europe, and the lavish use of them requires a princely income. Consequently, some of these cheaper plants, e.g., California privet, Hall's honeysuckle, and Wichuraiana roses, are available even to the poor, while the whole list is of special interest to people who have summer homes.

#### Ornamental fruits of autumn.

The extraordinary beauty of shrubs with brightly colored berries was first publicly and sufficiently demonstrated in this country by the Arnold Arboretum. Compared with autumnal colors of foliage, the fruits present fewer, smaller, and more jewel-like masses. Amid the bewildering variety one may discern three groups.

First are the short-lived fruits, which drop soon after the killing frost, or present an unattractive appearance owing to decay. Here belong the vast majority of ornamental fruits, including crab apples, dozens of hawthorns, *Viburnum*, *Lantana*, *V. alnifolium*, *V. cassinoides*, *V. Sieboldii*. The chief function of this class is to suggest the fecundity and variety of nature in autumn, but attractive thorneries have been designed, and the ornamental fruits of the Rosaceae are now used to connect the battle-scarred remnants of old orchards with modern ornamental planting, especially boundaries.

The second group comprises all the fruits that remain attractive until Christmas, e.g., the rugosa rose.

The third and most valuable group comprises those that remain attractive all winter, like the barberries. This and the second group are classified by color under *Winter Gardening* (Vol. VI.)

Most persons are willing to sacrifice some degree of ornament in order to attract the birds. The following furnish food in autumn, when it is especially desirable to attract the migrants to the South: the flowering dogwood, red osier, and alternate-leaved dogwood, choke-cherry, black and sweet elder, arrow-wood, sassafras, kinnikinnick, crab-apple, hawthorn, fire-thorn, cotoneaster, buffalo berry, tupelo, and mountain ash.

#### Landscape forestry in autumn.

Private and public woodlands in the East are more beautiful than a decade ago, in spite of the destruction of magnificent chestnut trees, and this is true, although probably to a lesser extent, in other parts of the country. The sudden spread of the chestnut disease has brought certain compensations. For example, the flowering dogwood, which was formerly kept down, has prospered mightily, making the woods showier both in May and September; and other vegetation changes are following.

There is arising a general interest in pleasure woods, as witness the term "landscape forestry," which was unknown ten years ago. We are beginning to make personal use of woods. Judged by English standards, American woods are too crowded by crooked and spindling trees for comfort, and the general lack of evergreens robs them of mystery and charm. Our most urgent needs, therefore, are thinning, drives, paths, and the restoration of evergreens, all of which are especially enjoyable during the autumn and nutting season. Mistaken zeal has denuded many woods of undergrowth, which should quickly be restored along drives and paths. To glorify the woods on dark autumnal days, it is well to use masses of witch hazel, the foliage of which furnishes one of the cheapest and quickest ways of getting great sheets of sunny color.

Unfortunately the eastern mountains have been devastated so often by fires and lumbermen that there is comparatively little variety, the chief masses of color being furnished by quick, short-lived species, like poplars, birch and balsam, which are mere weeds compared with the more enduring and valuable oaks and pines. Our greatest problems are the restoration of variety and of long-lived species. In such work the fashionable colonies in the Berkshires ought to take the lead, since the social season reaches its height at Lenox in September. The Arnold Arboretum presents one of the most artistic, and probably the most varied, autumn landscapes made by man.

WILHELM MILLER.

**AVÈNA** (the old Latin name). *Gramineæ*. OATS. Mostly annuals with open panicle and large spikelets.

Spikelets 2-6-fl.; rachilla bearded below the florets; glumes about equal, large and membranaceous, many-nerved, usually as long as the spikelet; lemmas indurated, bidentate at apex, bearing a stout twisted awn on the back (this often straight or wanting in the cultivated oat).—Species about 50, of the temperate or cooler regions of the world. Scarcely grown as ornamental subjects.

**fátua**, Linn. WILD OATS. Resembles the cultivated oat, but differs in having long, brown hairs on the lemmas: spikelets usually 3-fl.; glumes 1 in. long; awns of lemmas about an inch long. Dept. Agric., Div. of Agrost. 20:94.—Intro. from Eu., especially on the Pacific coast, where it is a troublesome weed. In the latter region the spontaneous growth is frequently used for hay.

**sativa**, Linn. CULTIVATED OATS. Spikelets usually 2-fl.; lemmas glabrous, awns usually straight or wanting. See Cyclo. Agric. I.

**stérilis**, Linn. ANIMATED OATS. Resembles *A. fatua* but the spikelets larger, the glumes about 1½ in.; awns 2-3 in.—Occasionally cult. as a curiosity, the florets when moistened presenting spontaneous movements due to the twisting and untwisting of the awns as they absorb or give off moisture.

*A. elatior* = Arrhenatherum elatius.

A. S. HITCHCOCK.

444. Averrhoa Carambola. (× 1/2)

**AVERRHŌA** (after Averrhoes, the Arabian physician). *Oxalidaceæ*. Tropical fruit trees, cultivated in India and China, and sometimes grown under glass for ornament.

Leaves alternate, odd-pinnate; lfts. alternate, ovate-acuminate, entire, stalked, sensitive: fls. borne on the naked sts. and branches, minute, fragrant, rose-colored to reddish purple in axillary or lateral cymes which are often panicle-like; calyx red; corolla campanulate; petals 5. See N. Amer. Fl. 25:57 (1907).

**Carambôla**, Linn. CARAMBOLA. Fig. 444. Height 15-30 ft.: lfts. 5-10; fls. rosy purple borne in the lf.-axils: fr. varying in size from a hen's egg to a large orange, ovate, acutely 5-angled, yellow, fragrant, the pulp acid. P.M. 15, p. 231. Rheede, Hort. Ural. 3, pl. 43, 44. Cav. Diss. pl. 202.—Cult. sparingly in S. Calif., and frequent in W. Indies. The half-grown fr. used as pickles; the ripe fr. for preserves. There are said to be two varieties, the sweet and sour, the former being eaten. Said to produce 3 crops a year. Leaves responding to the touch.

*A. Bilimbi*, Linn. CUCUMBER TREE. BILIMBI. Height 20-60 ft.: lfts. usually 31-45 pairs: fls. red, in longer clusters than the above and borne on branchlets from the hard wood: fr. smaller than the carambola, cucumber-shaped, smooth, green rind, and acid pulp. Extensively cult. in S. Amer. P.M. 15, p. 231. Rheede, Hort. Mal. 3, pl. 45:46. Lam. Encyc. pl. 385.

N. TAYLOR.†

**AVICENNIA** (from *Avicenna*, the Latin name of an illustrious physician of the Orient, 980-1036). *Verbenaceae*. **BLACK MANGROVE**. **WHITE MANGROVE**. Trees or shrubs usually growing in mangrove swamps and on the shores of tropical estuaries, remarkable for the vertical leafless breathing-stems that rise above the soil from their long spreading horizontal roots.

Leaves opposite, entire, coriaceous, persistent: fls. small and inconspicuous in axillary cymes; calyx cup-shaped, deeply 5-lobed; corolla bell-shaped, whitish, 4-lobed; stamens 4, inserted on the corolla-tube, exserted, bearing ovate, 2-celled anthers; ovary sessile, 1-celled, ovate, tapering upward into a slender 2-lobed style, and containing 4 ovules suspended from a central placenta: fr. ovate, oblique, opening by the ventral suture and exposing the expanding embryo, before dropping off; embryo with broad, fleshy conduplicate cotyledons.—Three species now recognized: *A. nitida* which reaches S. Fla. and La., *A. officinalis* of Polynesia and the E. Indies, and *A. africana* of the west coast of Afr. Planted on the shores of estuaries to prevent washing by tidal currents, they collect floating debris by means of their erect breathing-sts., and by this means aid in extending the shoreline seaward.

*nitida*, Jacq. **BLACK MANGROVE**. **WHITE MANGROVE**. **HONEY MANGROVE**. **SALT-BUSH**. A tree, usually of moderate size but sometimes 60 to 70 ft. high, with a short trunk, and spreading crooked branches: inner bark bright orange-red, outer bark scaly, deciduous, dark reddish brown: young branches hoary-pubescent, at length glabrous and marked with interpetiolar lines and conspicuous lf.-scars: lvs. opposite, oblong or lanceolate-elliptical, gradually narrowed at the base, coriaceous, deep green and glossy above, whitish or grayish beneath, 2 or 3 in. long and about 1-1½ in. broad: fls. inconspicuous, fragrant, borne in few-fl. spikes on angled canescent peduncles, closely invested with small bracts; corolla whitish, about ½ in. diam. when expanded, the lobes slightly tomentose on both surfaces, and the 4 anthers together with the style protruding from the nearly closed throat: fr. oblong or elliptic 1-2 in. long and about 1 in. broad. Mangrove swamps and shores of estuaries, Fla., Miss., and Texas; also Trop. Amer.—The fls. are very rich in honey, on which account bee-keepers in certain parts of Fla. transport their entire apiaries to the coast, along the Indian River during the season of blooming, which occurs in June and July. The honey produced is white and clear, and of excellent flavor, and always commands the highest market-price. The embryo begins to germinate while the fr. is still on the tree. When it drops off, the two cotyledons unfold into a miniature boat, floating on the tide, which distributes the fr. along the shores of bays and lagoons and carries it to the outlying keys. Crystals of salt are often deposited on the lvs., on which account this species is sometimes called *palo de sal*, or salt-bush. W. E. SAFFORD.

**AVOCADO**. (*Persea gratissima*, Gaertn.). Figs. 445, 446. One of the most highly valued of tropical fruits. It is commonly grown in Mexico, Central America, parts of South America, the West Indies, and Hawaii; to a limited extent in India, Madagascar, Reunion, Madeira, Samoa, Tahiti, Algeria, Queensland, and other tropical and subtropical countries. In Florida and California, its cultivation is conducted commercially. See *Persea*.

The avocado is considered by most authorities to be indigenous to Mexico, Central America, and South America to Peru and Brazil. From the Aztec *ahuacatl* has been derived the Spanish adaptation *ahuacate* or *aguacate*, the name in general use in Spanish-speaking countries. *Avocado* is an adaptation in use in the United States and other English-speaking countries; *avocat* in the French colonies. *Alligator pear* is a misleading corruption that should be dropped.

Seedling avocados grow to a height of 50 or 60 feet; when budded the tree is considerably dwarfed. The leaves are elliptical to oblong-lanceolate, varying from 4 to 8 inches in length, persistent, deep green, the new growth frequently wine-colored. The tree is worthy of a place in every dooryard for shade and ornament. The small, greenish flowers are produced in great abundance on loose axillary racemes.

The fruit is variable in form, color, and size, as well as in quality and minor characters. The form ranges from oblate or spherical to slender pyriform, including a great variety of shapes, one of the commonest being broad pyriform. The color may be light or dark green, purple, crimson, or maroon. The fruit varies from 1 to 6 inches in diameter, and in weight from a few ounces to three or four pounds. The skin is sometimes soft and pliable, and no thicker than that of an apple;

445. Avocado tree.

in other forms it is coarsely granular, woody, and ⅛ inch thick,—in reality almost a shell. Inclosed by it is a mass of yellowish pulp, of the consistency of firm butter, and of delicious nutty flavor. The avocado is unlike most other cultivated fruits in the fact that it contains a large amount of vegetable oil, sometimes as much as 18 per cent; hence it can be considered more as a food than as a dessert. It is used in numerous ways, the commonest being as a salad, with the addition of salt, pepper and an acid. Sometimes it is cut in half, the seed removed, and the flesh eaten with a spoon, as muskmelons are eaten, salt or other condiment being added. The single, spherical or conical seed is frequently as large as a hen's egg. It is provided with two more or less distinct coats, which sometimes adhere to the seed, and in other instances to the flesh.

In recent years the avocado has been given systematic attention in the United States, both in regard to cultivation and varieties. Previous to 1900, propagation was exclusively by seed, and as the species is variable when grown in this way, many trees produced inferior

fruit and commercial cultivation on a sound and profitable basis was not possible. The choicest varieties are now propagated by budding and are grown on a large scale.

The diverse climatic conditions under which the avocado is found enable varieties to be obtained which are suited to regions with cool climates as well as those which are strictly tropical. In Mexico the fruit has been grown for centuries at altitudes of 6,000 or 7,000 feet, where severe frosts are experienced each winter; varieties from such regions, as opposed to those from hot and humid lowlands, are suitable for cultivation in those parts of California and Florida in which slight frosts are the usual winter occurrence. When mature, some types will stand temperatures as low as 20° F. without injury, if in proper condition at the time of the freeze; others will not withstand lower than 27° or 28° without serious damage.

The subject of races or types has not been given systematic attention outside of the United States, and no attempt at classification has been made, other than brief descriptions of types found in limited areas in Mexico and Central America. In California two very distinct types are grown, commonly referred to as the Mexican and the Guatemalan; the former (*Persea drymifolia* of some botanists) is ordinarily a small fruit, four to eight ounces in weight, oval or pyriform, and thin-skinned. It is one of the hardest types in cultivation and very productive, as a rule. The Guatemalan type is characterized by its thick, woody skin, frequently rough or tuberculate on the exterior; the fruits are medium-sized. It is considered one of the best for commercial use, as it can be shipped without difficulty. The type grown in Florida is usually referred to as the West Indian-South American. It has a skin sometimes as thick as the Guatemalan, but of softer texture; some varieties are of large size and attractive appearance, but the type is rather susceptible to frost.

The avocado has been subjected to systematic cultivation for so brief a period that a large number of named varieties has not been established. In Florida the Trapp is the most widely planted and is, in fact, the standard commercial variety, Pollock occupying the place of next importance. Several others are grown to a limited extent, including Family, Rico, Blackman, and Wester. In California some of the most promising varieties are Taft, Lyon, Meserve and Murrieta; a number of others have been disseminated. Several named varieties have been established in Hawaii.

For commercial cultivation, winter-fruited varieties have been found to be the most valuable, since northern markets are almost destitute of fresh fruit during that season. It is desirable, however, to have a supply, for local consumption at least, during other seasons of the year. Fortunately varieties are obtainable which ripen at widely different times,—in California fruit is in the markets fully ten out of the twelve months, although the season in Florida, at the present time, is not so long. A variety running uniformly about a pound in weight appears to be the most desirable, and if the fruit is round or oval, it can be more advantageously packed and shipped than if pear-shaped or "bottle-necked." The skin should be sufficiently thick and tough to withstand shipment without undue care in packing, and the seed should be as small as possible. It is also important that the seed be tight in its cavity, for in the loose-seeded varieties, the flesh is often seriously damaged by the seed shaking around while the fruit is in transit. Flavor and quality must of course be up to the standard, there being a wide difference among the varieties in these respects.

Large seedling trees of the small-fruited Mexican type sometimes produce as many as 2,000 or 3,000 fruits in a season, while a large-fruited variety may not produce more than a few dozen. Two or three hundred

fruits may be considered a good crop for a tree of a medium-sized variety.

In Florida, budded trees are planted in orchard form 20 feet apart; in California the distance is increased to 24 or 25 feet. Seedlings must be given more room,—30 feet at least. A well-drained, sandy loam is the soil best suited to the avocado, drainage being the most important requirement. For this reason it is best, where possible, to select a sloping piece of ground as a site for the orchard. Heavy soils, such as clay and adobe, will grow the tree successfully if the drainage is good.

Transplanting is best done in early spring, after danger of frost is over, but before the tree has started into new growth. In climates such as those of California and Florida, the tree is in a semi-dormant state after the cool weather of winter, and can be moved with little difficulty. A ball of soil should be taken with the roots, and the top pruned moderately. In light soils which cannot be balled, the trees should be transferred to pots or boxes and allowed to establish themselves, after which they may be set out in the orchard without disturbing the roots. When the budded trees have been grown in pots, the possibility of injuring the delicate roots is eliminated.

The cultural requirements of the avocado are similar to those of the citrus fruits. In dry climates the trees must be irrigated regularly and frequently, particularly during the first two or three years. For bearing trees a fertilizer containing 3 per cent nitrogen, 5 per cent phosphoric acid, and 12 per cent potash has been recommended, the quantity required each season varying from three to ten pounds per tree, according to the character of the soil. This should be applied in several doses during the growing season. The growth of young trees is greatly encouraged by organic nitrogen. Leguminous cover-crops are very desirable, for the humus they will furnish as well as the nitrogen.

Often there is a tendency, especially in seedlings, to shoot upward and not spread out; this must be checked by heading back. All weak or unshapely growths should be trimmed out, and all wounds made when pruning should be covered with grafting wax or paint to prevent the entrance of any fungus into the wood. It is well to keep the trees headed low to prevent damage from winds as much as possible; this also brings the fruit within easy reach for picking.

In regions subject to severe frosts, the trees should be protected during the first two or three winters with a shelter of palm leaves, corn stalks, burlap, or some such material. Where irrigation is practised, it is well to harden the trees by withholding water in late fall.

In Florida the avocado is attacked by the wither-tip fungus (*Colletotrichum gleosporioides*), which can be controlled with bordeaux mixture. Two or three scale insects have been noted on trees in California, but up to the present time they are not of serious importance, with the exception of the black scale (*Saissetia oleæ*), which sometimes requires combative measures. The avocado mealy bug (*Pseudococcus nipæ*) is troublesome in Hawaii.

For market purposes, the fruit should be graded according to size, color and form, and carefully packed; it is essential, if the fruit is to be shipped any distance, to select varieties having good carrying qualities. Light wooden crates are used for shipping, containing one layer of fruits, and provided with good ventilation. The fruits must be separately wrapped in pieces of strong paper, and packed closely together to prevent their shaking about and becoming bruised. If they are to be shipped long distances, refrigeration is essential, experiments having shown that the temperature should be 40° to 45° F. Prolonged storage in temperature lower than 40° results in decomposition of the flesh.

Seedlings do not usually bear as early as budded trees, and on account of the variation which they are

likely to show in productiveness, as well as in form, size and quality of fruit, they are unsuitable for commercial cultivation. For the home grounds, on account of their ornamental value, they are worth planting; it is imperative, however, to select seeds from the most desirable fruits, of known quality and productiveness.

The avocado is budded on seedlings of the same species. For nursery purposes the seeds are usually planted singly in pots or in rows in the open ground. They may also be planted in flats, and potted off as soon as they have germinated; as the roots are delicate and easily injured, however, this is not a desirable method. A glasshouse is unnecessary, provided the seeds are planted during warm weather, but they are usually started under a lath or slat covering of some kind. Seeds will not retain their vitality very long, and should be planted as fresh as possible. Pots or boxes less than 4 inches in diameter should not be used. The soil should be light and porous, preferably rich in humus. Most avocado seeds are somewhat conical; they should be planted with the pointed end up, leaving the tip projecting above the surface of the soil. The pots should then be plunged in a frame, covered with straw or litter, and kept continually moist, but not soggy. Germination will take place in two or three weeks if conditions are favorable. If planted in the open ground, the seeds should be placed in rows 3 or 4 feet apart, and 14 inches apart in the row, covering them with an inch or two of soil. It is well to cover the ground with a mulch of straw to prevent evaporation as much as possible.

The avocado is a rapid grower, and young plants require frequent repotting. It is also a gross feeder, so that a rich soil should be used. The plants may be budded either in pots or in the open ground; if in the former, they must be given very careful attention so as to keep them growing vigorously, and should be in 6- or 8-inch pots. They may be budded when  $\frac{3}{8}$  inch in diameter, or even slightly less.

For avocados, shield budding, essentially the same as practised with the citrus fruits, is most successful and advantageous. The amateur may have some trouble in performing the work successfully, but after a little experience, few difficulties will be encountered.

The season at which budding is most successful naturally depends somewhat upon the locality. In Florida, late autumn and winter budding is favored; in California, May and June seem to be the best, although good success is often obtained in the fall; in Hawaii winter and early spring are preferred. Probably the work can be done at any season when the bark will slip readily, but all seasons are not equally advantageous.

Selection of budwood is one of the most important matters, and one likely to give the novice most trouble. If the wood is too old or too far advanced, the buds are almost certain to drop, leaving a "blind" shield; this may happen even when good budwood is used, if the stock is not in vigorous condition. The ideal wood is of recent growth, but hardened up sufficiently so that it does not snap on bending, and having plump, well-developed buds.

446. Avocado.

It is essential that the buds be cut large,—not less than  $1\frac{1}{4}$  inches in length, and thick enough so that a small quantity of wood will be taken. In budding large stocks,  $\frac{3}{4}$  inch in diameter, 2 inches is not too long for the bud, provided the budstick is, as it always should be, not less than  $\frac{3}{8}$  inch in diameter. The budding-knife must be as keen as a razor, and kept in as nearly that condition as possible by frequent stropping or whetting the knife after cutting each thirty or forty buds. The incision in the stock may be made either in the form of a T or an inverted T, preferably the latter, which has the recommendation of the most successful avocado budders. In lifting the bark be careful not to injure the delicate tissues which lie under it, and push the bud in very gently. Tie it in firmly with waxed tape, leaving the eye exposed.

In three to five weeks the bud will have united with the stock, and the wrap should be loosened; it should not be entirely removed until the bud has made a growth of 3 or 4 inches. Force the bud into growth by partly girdling the stock 3 or 4 inches above it, or by cutting

off the stock about a foot above it. Lopping is difficult, as the wood is brittle and will frequently break off rather than be lopped. The stock must be gone over every week and all adventitious buds rubbed off. When the bud is 8 or 10 inches high, the stock may be trimmed off close above it, and the stump covered with paint or grafting-wax.

Both inarching and grafting are practised to a limited extent, the latter usually under glass. Neither of these methods is so desirable as budding. Cuttings can be grown if bottom heat is available but trees produced in this way do not seem to have the vigor of budded trees.

Large, unproductive or undesirable seedlings should be worked over to a good variety. This is not difficult to do by budding; grafting is also possible. Cut the tree back severely in spring, leaving only the stumps of the largest branches, 3 or 4 inches in diameter, and painting the cut ends with white lead. Numerous sprouts will soon make their appearance; all but three or four of these on each branch must be rubbed off, and when these have attained a diameter of  $\frac{3}{4}$  inch they can be budded in the same manner as seedlings. It is necessary to loosen the wraps oftener, however, as the sprouts naturally make a very rapid growth. Old trees worked over in this way will often produce fruit in two years.

F. W. POPENO.

**AZÀLEA** (from Greek *azaleos*, dry: Linnæus believed them to grow in dry locations). *Ericacæ*. See *Rhododendron*.

The genus *Azalea* seems botanically inseparable from *Rhododendron*; there are no characters by which the two genera can be clearly separated, though if one looks only at the American species and those generally in cultivation, the differences seem to be clear enough, but if one takes into consideration the whole genus, particularly as it is represented in Asia, where it reaches its greatest development, one finds many species that have the characters of these two groups combined in various ways and render a natural and clear separation impossible.

Most of the species retain the same specific or varietal name under *Rhododendron*, except the following:

*A. álba*, Sweet=*Rhododendron rosmarinifolium*.—*A. balsaminiflora*, Carr.=*R. indicum* var. *rosiflorum*.—*A. californica*, Buckl.=*R. occidentale*.—*A. Danielsiana* Paxt.=*R. indicum* var. *macranthum*.—*A. ledifolia*, Hook.=*R. rosmarinifolium*.—*A. liliiflora*, Poir.=*R. rosmarinifolium*.—*A. lutea*, Linn.=*R. calendulaceum*.—*A. mollis*, Blume=*R. sinense*.—*A. mollis*, Miq.=*R. japonicum*.—*A. mucronata*, Blume=*R. rosmarinifolium*.—*A. pontica*, Linn.=*R. luteum*.—*A. procumbens*, Linn.=*Loiseleuria procumbens*.—*A. punctata*, Sweet=*R. rosmarinifolium*.—*A. reticulata*, Koch=

*R. rhombicum*.—*A. Rollisonii*, Hort.=*R. indicum* var. *rosiflorum*.—*A. Sieboldii*, Miq.=*R. indicum*.—*A. speciosa*, Willd.=*R. calendulaceum*.—*A. squamata*, Lindl.=*R. Farrerae*.

ALFRED REHDER.

**AZÀRA** (I. N. Azara, a Spanish promoter of science, especially of botany). *Flacourtiaceæ*. Ornamental shrubs or small trees grown for their handsome evergreen foliage and also for their fragrant flowers.

Leaves evergreen, alternate, short-petioled, entire or serrate, with usually one of the stipules enlarged and lf.-like; fls. small, in axillary peduncled racemes or clusters, apetalous; sepals 4-5; with glands between the stamens and the sepals opposite the latter; stamens numerous, rarely 5; ovary superior, 1-celled, with numerous ovules; style simple, elongated; fr. a many-seeded berry.—About 20 species in S. Amer., especially in Chile.

They are handsome evergreen shrubs, with small or medium-sized foliage, inconspicuous but fragrant flowers, and therefore called "aromo" in Chile.

They can be grown only in warmer temperate regions; the hardiest species is *A. microphylla*. They are sometimes cultivated as greenhouse plants and potted in a sandy compost of loam and leaf soil. Propagation is by seeds or by cuttings of mature wood in autumn under glass with slight bottom heat.

*microphylla*, Hook. f. From 3-12 ft.: lvs. obovate, serrate, or nearly entire,  $\frac{1}{2}$ - $\frac{3}{4}$  in. long, shining, glabrous, the stipules similar, but half the size; fls. greenish in few-fl. clusters; stamens 5; berries orange. Feb., March. Chile. G.C. II. 1:81. Gn. 18, p. 403. Gt. 23, p. 340. F. 1874, p. 221.—Graceful evergreen shrub, regularly pinnately branched, excellent for covering

walls; the hardiest of all the cult. species; hardy as far north as Washington, D. C.

*Gilliesii*, Hook. & Arn. Height 10-15 ft.: lvs.  $2\frac{1}{2}$ -3 in. long, broad-ovate, with coarse, spiny teeth, glabrous; stipules orbicular, much smaller; fls. in dense, elliptic, nodding heads, yellow. Feb., March. Chile. B.M. 5178. F.S. 23:2+45. G.C. II. 15:401.—The handsomest of all azaras.

*A. crassifolia*, Hort.=*A. Gilliesii*.—*A. dentata*, Ruiz. Height 12 ft.: lvs. obovate or elliptic, crenate-serrate; fls. yellow, in small corymbs. Chile. B.R. 1788.—*A. integrifolia*, Ruiz. Height 10-20 ft.: lvs. entire; fls. yellow, in oblong heads. Chile. Has a variegated form.

ALFRED REHDER.

**AZÓLLA** (Greek, *to destroy by drying*). *Salviniaceæ*. A small genus of floating aquatics with small, pinnately branched sts. and minute fleshy 2-lobed lvs., producing 2 sorts of spores in globular sporocarps. The plants multiply rapidly by self-division, and will grow readily in water containing a little nutriment. The species are distinguishable only by microscopic examination. In natural conditions, the plants grow so closely together and multiply so rapidly as to cover very completely any quiet water surface. For this reason, they have been found useful in preventing the propagation of mosquitos in Germany and Panama.

*caroliniana*, Willd. Plant  $\frac{3}{4}$ -1 in. long; anchor-like processes of spores with septa. N. Y. to the Gulf of Mex.

*fiiculoides*, Lam. Plants 1-2 in. long; anchor-like processes without septa. Calif. to Chile.

L. M. UNDERWOOD.  
R. C. BENEDICT.†

# B

**BABIÀNA** (said to come from Dutch for *baboon*, because those animals eat the bulbs). *Iridaceæ*. About fifty cormous plants of South Africa (and one Socotran), sometimes grown for spring bloom under glass, or in the open in the South.

Usually less than 1 ft. tall: fls. showy, red or purplish, in a short spike-like cluster or raceme, tubular at the base, the segms. with claws or narrow bases, and the limb erect-spreading, in marked colors and shades, often fragrant; ovary 3-loculed: lvs. narrow, hairy, plaited, standing edgewise to the st.

Low plants, of easy culture if treated like freesias or hyacinths. Three or four corms placed in a 4-inch pot, in autumn, give attractive bloom in March or later. Grown only indoors or under frames in the North. Outdoors in mild climates they may remain continuously in the ground, although it is better to take up and replant every year or two. Propagation is by cormels and seeds. They are showy and useful plants. Monograph by Baker in Handbook of the Iridæ, 1892.

A. *Perianth-limb regular or nearly so, and wide-spreading.*

**stricta**, Ker (*B. villôsa* and *B. purpurea*, Ker). Fig. 447. Plant 1 ft. or less high: lvs. broad, oblong-lanceolate or sword-shaped, barely reaching the spikes: fls. scattered, showy, usually red or purple, with a prominent tube, the segms. oblong-lanceolate. B.M. 583, 621.—Babianas are not sold under species-names in this country, but as mixed varieties. These varieties are chiefly, if not wholly, of this species. There are many forms and colors. Var. **angustifolia**, Sweet. Lvs. linear: fls. blue, pinkish inside. B.M. 637. Var. **rubro-cyanea**, Ker. Limb lilac, throat red. B.M. 410 (as *lxia*). Var. **sulphurea**, Ker. Yellow or whitish. B.M. 1053. Two other long-cult. types are described below.

AA. *Perianth-limb distinctly ringent or gaping.*

**plicata**, Ker. Low: lvs. lanceolate, hairy, usually overlapping the spikes: fls. lilac or red, long-tubed, the segms. oblong and unequal; odor pink-like. B.M. 576.

**dística**, Ker. Differs from the last in having the perianth-tube distinctly exerted from the spathe; odor hyacinth-like. B.M. 626.

*B. flabellifolia*, Harv. Fls. 2-5, in erect spike, long-tubed, lower lobes blotched: lvs.  $\frac{3}{4}$  in. broad, toothed at apex.—*B. ringens*, Ker. 6-10 in.: fls. gaping and ringent, scarlet: lvs. narrow and pointed.—*B. sambucina*, Ker. 6-10 in.: fls. purplish, with spreading divisions, elder-scented. B.M. 1019.—*B. socotrana*, Hook. f. 3-4 in.: fl. single, the tube very slender, pale blue, 2-lipped: lvs. narrow-lanceolate. Isl. of Socotra. B.M. 6585.

L. H. B.

**BABY'S BREATH**: *Gypsophila*; also *Galium* and *Androstaphium*.

**BACCAÛREA** (Greek, *bacca*, berry, and *aureus*, golden, from the yellow fruit). *Euphorbiaceæ*. Trees, rarely

cult., some with edible fr.: lvs. large, alternate, simple: infl. racemose; calyx imbricate; petals absent; 2 ovules in each of the 2-5 cells.—About 50 species in the Old World tropics: related to *Antidesma*. **B. bracteata**, Muell. Arg. (*Pierardia dulcis*, Wall.), is mentioned as once intro. to England. Malaya. Seed of **B. Motleyana**, Muell. Arg., of Malaya where the fr. is used, has been intro. by the U. S. Dept. Agric.

J. B. S. NORTON.

**BÁCCHARIS** (*bakkharis*, an ancient Greek name for different shrubs). *Compósitæ*. **GROUNDSEL TREE**. Ornamental plants, chiefly grown for the showy white pappus of the fruit; some species also for their evergreen foliage.

Shrubby or suffruticose: lvs. alternate, usually serrate, glabrous, deciduous or evergreen: heads of fls. small, white or yellowish, dioecious, in panicles or corymbs; involucre with many imbricate scales; receptacle flat, naked; pistillate fls. with filiform corolla: achenes compressed, ribbed, with pappus.—More than 250 species in Amer., chiefly in S. Amer.

*Baccharis halimifolia* and *B. salicina* are hardy North, while the evergreen species are more tender. They grow in almost any well-drained soil in a sunny position, and are well adapted for dry and rocky slopes, and valuable for seashore planting. Propagation is by seeds, or by cuttings under glass.

**halimifolia**, Linn. Shrub, 3-12 ft.: branches angular: lvs. cuneate, oblong or obovate, coarsely toothed, the uppermost entire, glabrous, 1-2 in. long: fls. in large panicles: pappus white, about  $\frac{1}{2}$  in. long. Sept. Seacoast, from New England southward. Gng. 7:113.—The hardiest species; in fr. resembling a shrub with abundant snow-white fls.

*B. glomeruliflora*, Pers. Allied to *B. halimifolia*: heads axillary, solitary or clustered, sessile or nearly so: pappus somewhat shorter. N. C. to Fla.—*B. patagonica*, Hook. & Arn. Low evergreen shrub: lvs.  $\frac{1}{4}$ - $\frac{1}{2}$  in. long: heads mostly axillary. Patagonia.—*B. pilularis*, DC. Height 6 ft.: evergreen: lvs. 1 in. long: heads in racemose panicles. Pacific coast.—*B. salicina*, Torr. & Gray (*B. salicifolia*, Nutt.). Allied to *B. halimifolia*. Lvs. narrow-oblong, or linear-lanceolate. Colo. to W. Texas.

ALFRED REIDER.

**BACHELOR'S BUTTONS**: *Centaurea Cyanus*, *Gomphrena globosa*, *Ranunculus acris* and *Ageratum conyzoides*.

**BACKHOÛSIA** (James Backhouse, botanical traveler). *Myrtiææ*. Evergreen greenhouse plants, blooming in spring.

Shrubs or trees, with opposite lvs. and blossoms in cymes or umbels: calyx-tube turbinate, or broadly campanulate, adhering to base of ovary, with 4 persistent segms.; petals 4, short; stamens many; ovary 2-celled, bearing a filiform style: fr. a caps., more or less inclosed in calyx, indehiscent or separating into 2 parts.—Five species in Austral. Requires the general treatment of myrtaceous coolhouse plants. Prop. by hardening cuttings under glass.

**myrtifolia**, Hook. & Harv. Large slender-branched shrub, or small tree: lvs. ovate-acuminate, stiff, pelucid-punctate: fls. white, in pedunculate corymbs, the younger ones partly concealed by the petaloid bracts; petals small, round-ovate, concave, acute; calyx hairy. Queensland and New S. Wales. B.M. 4133.

L. H. B.

**BÁCTRIS** (Greek, *baktron*, cane; the young stems used for walking-sticks). *Palmææ*, tribe *Bactrideæ*. Usually low palms, very rarely entirely spineless.

Stems solitary or fasciculate ringed, spiny or smooth, sprouting from the roots: lvs. terminal or scattering,

447. *Babiana stricta*. ( $\times \frac{1}{4}$ )

equally or unequally pinnatisect, glabrous or pubescent; segms. sparse or aggregated, or more or less imperfectly connate, forming a bifid blade, acute or rarely obtuse at the apex, the ciliate margins recurved at the base; petiole short or long; sheath long, spiny: spadices sessile or pedunculate, perforating the lf.-sheaths; spathes 2, the lower short, open at the apex, the upper coriaceous or woody, exceeding the spadix, or fusiform, ventrally dehiscent, smooth, bristly or spiny; bracts persistent: fls. small or medium, pale yellow or greenish: fr. small, green, ovoid or globose.—Species 90. Trop. Amer. G.C. II. 22:595.

These are ornamental palms, but little grown on account of the spines. The fruits of *B. major* are used extensively in South America for food.

The cultivation of *bactris* is easy if it is grown in a warmhouse, with a range of temperature from 60° to 80°, and given plenty of water. Frequent syringing is advisable. It thrives best in a mixture of loam, two parts; leaf-mold, one part; well-rotted cow-manure, one part. The young plants are very decorative, but in age most of the species become spindly.

Propagation is by suckers which grow freely; rarely by seeds, which are hard to get.

A. *Spines yellow, tipped black.*

*pallidispina*, Mart. (*B. flavispina*, Hort.). St. 10–18 ft. high, 1–2 in. diam., the internodes spiny: lvs. showy, 5–9 ft. long, equally interruptedly pinnatisect; petiole 4–6 ft., brown-scaly, thickly covered with very long ( $\frac{3}{4}$ – $2\frac{1}{4}$  in.), black-tipped yellow spines, either solitary or in groups of 2–4; segms. linear-lanceolate, caudate-acuminate, prickly on the margins, the basal ones 2–8 in. long,  $1\frac{1}{2}$  in. wide, the upper,  $12 \times 1\frac{1}{4}$  in.: fr. 3–4 times exceeding the persistent calyx, about  $1\frac{1}{2}$  in. long. Brazil.

AA. *Spines black.*

B. *Lf.-segms. acute at both ends.*

*major*, Jacq. BEACH PALM. St. 9–15 ft. high,  $1-1\frac{1}{2}$  in. diam., armed with rows of black spines 2 in. long: petiole armed with very long black, terete spines; lvs. 4–6 ft. long, equally pinnatisect nearly to the rachis; sheath and rachis spiny and white or brown tomentose; segms. linear, acute at both ends, 25–35 on each side, 1-nerved, 8–12 in. long,  $\frac{1}{2}$ – $\frac{1}{2}$  in. wide, glabrous on both sides, densely setose, with black hairs along the margin.: frs. about the size of an apricot, edible. Brazil.

*minor*, Jacq. Fig. 448. A tall, slender-stemmed palm, often 40 ft. in height, armed with many dark-colored spines: lvs. roundish in outline, about 3 ft. long and composed of numerous narrow, sharp-pointed lfts. that are spiny on the veins beneath: spathe axillary, solitary, spreading, very spiny; corolla in both sexes gamopetalous: fr. rotund, purplish black.—A rare but showy palm grown sometimes in tropics.

BB. *Lf.-segms. acute at tip.*

*Gasipañes*, HBK. (*Guilielma speciosa*, Mart.). St. about 60 ft. high, single or cespitose, with rings of subulate-compressed black spines, 1 in. long, the rings about as far apart as the diam. of the st.: lvs. 6 ft. long, curving; segms. dark green above, pale green below, very numerous, approximate,  $1\frac{1}{2}$  ft. long,  $1\frac{1}{4}$  in. wide, linear-lanceolate, long-acuminate, bristly or minutely prickly along the margins: fr. orange or reddish, nearly 2 in. long, ovoid. Lower Amazon.

*hórrida*, Oerst. Cespitose sts. 6–8 ft. high, 8–9 in. diam., very spiny, sheathed for most of its length with bases of dead lvs.; spines 3–4 in. long, 4-sided, whitish tomentose, at length glabrous: lvs.  $2\frac{1}{2}$ –3 ft. long; sheath 8 in., brown-tomentose; petiole  $1\frac{1}{2}$  ft., densely spiny, subtetragonal, densely brown-tomentose beneath; segms. 7 in. long,  $\frac{1}{2}$  in. wide, lanceolate, rigid, glaucous. Unlike all the above in having a hairy but not spiny spathe. Nicaragua

*B. aurantiaca*, Hort., is a "pinnate palm from Mex., dwarf and spiny but beautiful." The name is unknown in botanical literature.—*B. caryotaxifolia*, Mart., from Brazil, with wedge-shaped 3-lobed pinnae, has been catalogued; also *B. utilis*, Benth. & Hook. (*Guilielma utilis*, (Erst.), from Costa Rica, with spiny petioles and young lvs.

N. TAYLOR.†

**BACULÀRIA** (Latin, *baculum*, a small walking-stick) *Palmaceæ*, tribe *Arècæ*. Two or three small palms, completely spineless. By some, included in *Linospadix*.

Stems very thin, either solitary or in bunches, which are prominently ringed: lvs. usually numerous, terminal, unequally pinnate, and with relatively short petioles: lfts. coriaceous, usually alternate, from 4–6 pairs, strap-shaped, and with incised or much-laciniated apices, attached by a broad, almost decurrent base; nerves prominent, numerous on older lfts., on small ones solitary: spathes in pairs; spadix consisting of a long spike-like cluster, as long as or longer than the lvs.; fls. in 3's, a female with 2 males in each cluster on the green spadix: fr. small, obovate or ovoid, green, from  $\frac{1}{4}$ – $\frac{3}{4}$  in.

448. *Bactris minor*.

long. The genus is confined to temperate and tropical Austral. G.C. II. 22:595.

For general culture, see *Areca*, to which they are allied. The only species known in cultivation seem to do better in a temperate rather than a tropical house, but shifting will probably be found advantageous. One of the smallest palms in cultivation, *B. monostachya* is very popular, particularly in England.

*monostachya*, F. Muell. (*Arèca monostachya*, Mart. *Kéntia monostachya*, F. Muell.). WALKING-STICK PALM. Trunk 6–12 ft. high, scarcely 1 in. thick: lvs.  $1\frac{1}{2}$ –4 ft. long; the sheath broad, coriaceous, about 6 in. long, produced into 2 stipular lobes; segms. very irregular, acuminate, very variable in breadth and distance, adnate to the rachis, or tapering at the base, the longest about 1 ft. long; infl. very long, often exceeding the lvs.; stamens usually 10: fr. ovoid, about  $\frac{1}{2}$  in. thick. Queensland, New S. Wales. B.M. 6644.

*minor*, F. Muell. Sts. several from the same rhizome, 2–5 ft. high, about  $\frac{1}{2}$  in. thick: lvs. about  $3\frac{1}{2}$  ft. long, with from 12–14 lfts.: spadix about as long as the lvs. or a little shorter, scarcely  $\frac{1}{2}$  in. thick; stamens 12; seed about  $\frac{1}{2}$  in. diam. Queensland.—A delicate palm, not so well known as the preceding, but attractive.

N. TAYLOR.†

**BAERIA** (after the Russian zoölogist, Karl Ernst von Baer). *Compósitæ*. Small plants, one of which is sometimes grown as a garden annual.

Heads usually many-fl'd., radiate, the rays 5-15; bracts of the involucre as many as rays; pappus often wanting.—Twenty species of Californian annuals (or one or two perennial species), with numerous showy, inch-wide yellow fls. in early summer.

*gracilis*, Gray (*Burrielia gracilis*, DC.). Easily distinguished from *Actinolepis coronaria* by its hairy sts. and foliage and undivided lvs.: plant much branched: height 4-12 in.: lvs. opposite, connate, linear-lanceolate; fls. solitary, on slender terminal peduncles; involucre leafier than in *Actinolepis coronaria*, the scales longer, downy, in 2 series; rays 8-12. B.M. 3758.—This is likely to be cult. as *Lasthenia californica*, which, however, is not hairy and has much longer lvs.

*B. chrysostoma*, Fisch. & Mey. Lvs. narrowly linear, 1 line or less wide; fls. larger than in *B. gracilis*, the heads 3-4 lines high; ligules 3-4 lines long; habit more erect.—*B. coronaria* = *Actinolepis coronaria*.

N. TAYLOR.†

**BAHIA** (probably from the port of Bahia, or San Salvador, South America). *Compósitæ*. A little-known group of herbaceous perennials or sometimes subshrubs grown for their yellow flowers and canescent leaves.

Leaves mostly opposite, rarely alternate, the rather small pedunculate heads terminating the branches; involucre hemispheric or obovate; receptacle mostly flat; achenes narrow, 4-sided; pappus of several scarios scales.—There are 12 species, all American. They thrive on borders of light and well-drained soil, and may be increased by seeds or by division in spring.

*lanata*, DC. One to 2 ft. high, slender: lvs. pinnately cleft or divided into 3-7 linear or linear-lanceolate lobes: rays mostly 8-9, oblong, showy: achenes glabrous or minutely hairy. Calif. B.R. 1167 (as *Eriophyllum*).—Perhaps not hardy in the N. E. Summer. N. TAYLOR.

**BAIKIÆA** (Wm. B. Baikie, African traveler). *Leguminosæ*. Great-flowered Trop. African trees of 2 species, one of which has been cult. in Eu. Trees unarmed: lvs. abruptly pinnate, coriaceous: fls. few in each raceme, not papilionaceous; petals 5, much exceeding the turbinate calyx, broadly oblanceolate or obovate, long-clawed; stamens 10. *B. insignis*, Benth., is an erect evergreen, to 40 ft., with short-lined fls. 10 in. across, snow-white with lower petal or lip lemon-yellow. Upper Guinea.—Said to be the largest flower in the Leguminosæ.

450. Pod of garden balsam

**BALÅKA** (the Fijian vernacular name). *Palmææ*, tribe *Arëææ*. Palms, differing, if at all, from *Ptychosperma*, to which they are with equal propriety referred, in having the seed not sulcate, and in the half-rhomboid segms. of the lvs.; and from *Drymophloeus* in the form of the lf. and the caducous spathes.—Species 2. Fiji Isls.

**Seemannii**, Becc. (*Ptychosperma Seemannii*, H. Wendl.). **BALÅKA**. Fig. 449. Caudex slender, 8-12 ft. high, straight, ringed, about 1 in. diam.: lvs. pinnatisect, 4 ft. long; segms. erose-dentate at the apex, alternate, 9 on each side, semi-rhomboid, obliquely truncate, the upper margin longer, cuspidate at the apex, the terminal one deeply bifid. Growing as underwood in dense forests. Fiji.—Sts. used for spears by natives, because of their strength and straightness. Fig. 449 is adapted from Seeman's *Flora Vitiensis*. N. TAYLOR.†

**BALLOON VINE**: *Cardiospermum*.

**BALM** (*Melissa officinalis*, Linn.). *Labiatæ*. **LEMON BALM** and **BEE BALM**. Sweet herb, the lvs. being used for seasoning, particularly in liquors, and also in medicine. It has a lemon-like flavor. It is a hardy perennial from S. Eu. The plant grows 1-2 ft. high, somewhat hairy, loosely branched, with ovate-petioled, sometimes cordate, lvs. and yellowish or whitish fls. in loose axillary clusters. Thrives in any warm position, and is easy to grow. Prop. by seeds; also by division. Becoming wild in E. U. S.

**BALSAM**, *Impatiens Balsamina*, Linn. (*Balsamina hortensis*, DC. *Balsamina Impatiens*, Hort. *Impatiens coccinea*, Sims, B.M. 1256). *Balsaminææ*. An erect, much-branched, half-succulent annual, long ago introduced from India, and now widely cultivated for its showy flowers.

Plant 1½-2½ ft.: lvs. lanceolate, toothed, the lower ones being mostly in pairs: fls. clustered in the axils of the lvs., on very short stalks; sepals and petals similarly colored and not easily distinguished, one of the sepals (of which there seem to be 3) long-spurred; petals apparently 3, but 2 of them probably represent 2 united petals, thus making 5; stamens 5. The pod, shown in Figs. 450 and 451, is explosive. It has 5 carpels and very thin partitions, and seeds borne on axile placentæ. When the caps. are ripe, a pinch or concussion will cause the valves to separate and contract, the seeds being thrown with considerable force. The balsam has varied immensely in the doubling, size and color of its fls. and in the stature of the plant. It was known to Gerarde in 1596. The balsam is sometimes called "lady slipper," although this name is properly confined to *Cypripedium*, and used for *Calceolaria*.

Practically all the garden balsams are now double or semi-double. The full-double forms are known as the camellia-flowered varieties. Fig. 452. In well-selected stock, the greater part of the flowers from any batch of seedlings should come very double. The colors range from white to dark blood-red, yellowish and spotted. Balsams are of very easy culture. They are tender, and should be started in thumb-pots or boxes indoors, or in the open when danger of frost is past. The seeds are large, and germinate quickly. The plants prefer a rich, sandy loam, and must not suffer for moisture. Transplanting, and

451. Explosion of balsam pod.

pinching-in the strong shoots, tend to make the plants dwarf and compact; two or three transplantings are often made. It is well to remove the first flower-buds,

452. Camellia-flowered balsam. (×1)

especially if the plants are not thoroughly established. Better results are secured when only a few main branches are allowed to grow, all the secondary and weak ones being pinched out. Sometimes they are pruned to a single stem, and if much room is given very large blooms are secured. The lower leaves may be removed if they obscure the flowers.

Well-grown bushy plants should stand 2 feet apart each way, and the tall kinds will reach a height of 2 to 2½ feet. Good bloom is impossible if plants are crowded. For this reason, balsams do well in rows on the border of a garden where they may have room. Seed of the finest double strains is expensive, but inferior or common seed gives little satisfaction. Plants started early in May should give flowers in July, and should bloom until frost. A full-grown plant is shown in Fig. 453. At present, balsams are grown chiefly as flower-garden plants; but some years ago the flowers were largely used as "groundwork" in florists' designs, particularly the double white varieties. The flowers were wired to toothpicks, and were then thrust into the moss that formed the body of the design. L. H. B.

**BALSAMOCÍTRUS** (Latin, *balsamum*, balsam, and *citrus*). *Rutaceæ*, tribe *Citrææ*. Trees; usually spiny, suggested as stocks for citrous fruits; as yet scarcely known in this country.

Fruits hard-shelled and persistent: lvs. trifoliate, or rarely simple: fls. 4-5-parted; stamens 10-20; ovary 8-9-celled; ovules numerous in each cell; seeds large, smooth; hypocotyl very short, the cotyledons remaining near or just above the surface of the ground. The first

453. The garden balsam.

foliage lvs. are opposite, lanceolate or ovate.—Three species are known, all occurring in Trop. Afr. *B. Dawei* is the type species.

The subgenus *Afrægle* (Latin, *Africa* and *Ægle*) differs from *Balsamocitrus* proper in having more than twice as many (usually 4 times as many) stamens as petals and in having a larger, more deeply lobed disk. *B. paniculata* is the type of this subgenus.

*Dawei*, Stapf. Fig. 454. A large tree, 50-60 ft. or more in height: first few foliage lvs. on young plants simple but next succeeding ones 3-foliolate; lateral lfts. three-fifths to three-fourths as long as the terminal lft., having a cylindrical petiolule  $\frac{3}{8}$ - $\frac{1}{2}$  in. long; terminal lft. with a much shorter petiolule,  $\frac{1}{8}$ - $\frac{1}{4}$  in. long, but usually borne on a section of the rachis  $\frac{1}{2}$ -1½ in. long, jointed both at the insertion of the lateral lfts. and also where the petiolule of the terminal lft. is inserted (such imperfectly pinnate lvs. are not uncommon in some pinnate-lvd. plants but are rare in trifoliate species): fls. 5-merous with 10 free stamens (twice as many as the petals): frs. globose or oval, 4-6 in. diam., with a very thick, hard woody rind and 8 oval cells surrounded by the more or less fibrous mesocarp tissue; cells contain numerous seeds imbedded in amber-colored, fragrant gum. The ripe frs. drop off the pedicel, leaving a hole through the shell where they were attached. The seeds are large,  $\frac{1}{2}$ - $\frac{3}{4}$  x  $\frac{1}{8}$ - $\frac{3}{16}$  in., smooth, and germinate with a very short hypocotyl, often bringing the cotyledons to the surface of the ground or just above it. Occurring in the Budongo forest east of Lake Albert Nyanza in Uganda, E. Cent. Afr., at an altitude of 2,000-3,000 ft.

—The seedlings grow very rapidly. Experiments indicate that this is a very promising stock on which to graft the bael fruit (*Ægle Marmelos*), which it is difficult to grow on its own roots. Ill. Journ. Linn. Soc. Bot. 37, pl. 22.

454. Fruit of *Balsamocitrus Dawei*. (×½)

*paniculata*, Swingle (*Citrus paniculata*, Schum. *Ægle Bārteri*, Hook. f. *Limonia Warnéckii*, Engler). Fig. 455. A handsome tree, 20-45 ft. high and much branched: lvs. on old trees trifoliate, the lateral lfts. about two-thirds as long as the terminal one and narrowed into a slender petiolule  $\frac{1}{8}$ - $\frac{1}{4}$  in. long; terminal lft. has a long slender petiolule  $\frac{1}{2}$ - $\frac{3}{4}$  in. long but there seems to be no articulation where it joins the lamina as in case of *B. Dawei*; spines are said to be solitary, from 1-4 in. long but are wanting on fruiting branches: fls. usually 4-merous, sometimes 5-merous; stamens 13-20, normally 4 times as many as the petals; ovary 8- or 9-celled; disk large, lobed: frs. spherical or obovoid, 3-5 in. diam., with a thick woody rind, green until maturity, then taking on a gray color; cells of fr. contain numerous smooth seeds; germination unknown.—Commonly planted in the villages of Nigeria and the Gold Coast in Trop. W. Afr. This species has not yet been intro. into cult., but it is to be hoped that seeds will be secured from Afr. to permit its being tested as a stock for citrous frs. Ill. Hooker, Ic. 37, pl. 2285. Bull. Soc. Bot. Fr. v. 58, Mem. 8d., pl. 1-2.

*gabonensis*, Swingle. A little-known tree or shrub: lvs. narrowly lanceolate, simple, with short petioles: vigorous young trees, when they have reached a height of 8 or 10 ft., begin to show trifoliate lvs. with relatively small lateral lfts. from one-third to one-half as long as the terminal lft. and like it acute at both ends; terminal lft. sessile: fls. unknown: fr. nearly globular, slightly pear-shaped, with a thick woody rind.—The natives remove the contents through an opening at the stem end and use

the empty fr. as a powder-flask. Native to the M'fan or Pahouin country in N. French Congo and S. Kamerun where the fr. is known to the French residents as "poire à poudre" (powder-flask). This species grows very rapidly under greenhouse conditions. It has been grafted successfully on the tabog (*Chætospermum glutinosa*), a related tree native to the Philippines, and may prove of value as a stock for citrous fruits on account of its vigor and healthiness. Ill. Bull. Soc. Bot. Fr. v. 58, Mém. 8d, pl. 3, and Fig. B., p. 235.

WALTER T. SWINGLE.

**BALSAMORRHIZA** (Greek, *balsam* root). *Compósitæ*. Low perennials with thick, deep, resinous, frequently tuberous roots, tufts of radical lvs., and large yellow fls.: lvs. usually long-petiolate, when cauline usually opposite, mostly radical: scapes few-lvd. or naked; fls. usually solitary. The root was an aboriginal food, when the rind was peeled.—About 10 species, mostly from Cent. and W. N. Amer.

**Hodkeri**, Nutt. Canescent: height 4–12 in.: lvs. lanceolate, 1–2-pinnately parted: fls. solitary, on naked scapes.—Intro. 1881 by E. Gillett, but scarcely known to horticulturists. Useful in dry situations.

N. TAYLOR.

455. *Balsamocitrus paniculata*. ( $\times \frac{1}{2}$ )

**BAMBOO**. Various perennial ornamental grasses embracing the genera and species of the tribe *Bambuseæ*, order *Gramineæ*, cultivated for the surpassing beauty of their foliage and habit; some of them are hardy even in parts of the northern states, but they are warm-country plants.

Usually large, sometimes tree-like, woody, rarely herbaceous or climbing plants, of wide geographical range. The species are irregularly distributed throughout the tropical zone, a few occurring in subtropical and temperate zones, attaining their maximum development in the monsoon regions of Asia.—About twenty-three genera, only two being common to both hemispheres. Something more than 200 species are recognized, of which upwards of 160 occur in Asia, about seventy in America, and five in Africa. They extend from sea-level to altitudes of more than 10,000 feet in the Himalayas and 15,000 feet in the Andes, and under the most favorable conditions some species may attain a height of 100 to 120 feet, with a diameter of culm of 8 to 12 inches.

An attempt to enumerate the numerous and varied economic uses of the giant-grasses would greatly overreach the field of this article; but as objects of grace and beauty in the garden, conservatory, and under special conditions of landscape, bamboos are matchless. Not only are they adapted to sections favored with a

gentle climate, but it is possible to grow certain species where the cold of winter may reach zero Fahrenheit, or even occasional depressions of greater severity.

Bamboos delight in a deep, rich loam, and generously respond to good treatment. A warm, slightly shady nook, protected from the prevailing cold winds of winter, and in which moist but well-drained soil is plentiful, is an ideal location. A top-dressing of manure and leaves is not only beneficial in winter, by preventing the frost from penetrating the ground too deeply, but it also preserves the moisture that is so essential to the welfare of the plants during the growing season. Some species produce rampant subterranean stems, and spread rapidly when once established. These should not be planted for ornamental purposes, but only those forming tufts or clumps. It is best to plant each group of but a single species, and to restrict the wide-spreading sorts to isolated positions. The most effective results to be obtained by planting bamboos are secured on gentle banks above clear water, and against a background of the deepest green. In such situations the graceful stems and dainty branches, bending with their wealth of soft green leaves, and the careless lines of symmetry of each individual, lend a bold contrast of the richest beauty. Ordinarily it will require two or three years thoroughly to establish a clump of bamboos in the open air, and, until this is accomplished, the vigor, hardiness and beauty that characterize some noble kinds will be lacking. During the first few years, a new plantation should receive generous protection in localities in which the winters are trying, and even with this precaution it is likely the plants will suffer to some extent in cold weather. Planted out in conservatories or confined in tubs or large pots, the bamboos present many admirable qualities, and, as decorative plants, several species offer many inducements to their cultivation, especially as they may be grown and used out-of-doors in the summer and cheaply wintered in a coolhouse.

Propagation is best effected by careful division of the clumps before the annual growth has started. The difficulty of procuring seeds in some instances is very great; indeed, the fruiting of a number of species has never been observed. Some species flower annually, but the majority reach this stage only at intervals of indefinite and frequently widely separated periods. In some species the flowers appear on leafy branches; in others the leaves fall from the culms before the flowers appear, or the inflorescence is produced on leafless, radical stems. Fructification does not exhaust the vitality of some species; but others, on the other hand, perish even to the portions underground, leaving their places to be filled by their seedling offspring. Owing largely to the difficulty in obtaining flowering specimens, the systematic arrangement or nomenclature of the bamboos is in a sad plight. As it is sometimes even impossible to determine accurately the genus without flowers, the correct positions of some forms are not known.

Four sub-tribes of *Bambuseæ* are accepted by Hackel, namely: *Arundinarieæ*.—Stamens 3: palea 2-keeled: fr. with the seed grown fast to the seed-wall. To this belong *Arundinaria* and *Phyllostachys*. *Eubambuseæ*.—Stamens 6: fr. with the seed fused to a delicate seed-wall. *Bambusa* is the only garden genus. *Dendrocalameæ*.—Stamens 6 (rarely more): palea 2-keeled: fr. a nut or berry. Here belongs *Dendrocalamus*. *Melocanneæ*.—Characters of the last, but palea not keeled. *Melocanna* is an example, an extra-tropical genus, probably not in cult. in the U. S.

The genera *Arundinaria*, *Phyllostachys*, *Bambusa* and *Dendrocalamus* contain the most important species in cultivation. Roughly, the species of *Arundinaria* may be separated from *Phyllostachys* by the persistent sheaths and cylindrical stems. In *Phyllostachys* the sheaths are early deciduous, and the internodes, at

least those above the base, are flattened on one side. Generally, *Arundinaria* and *Bambusa* cannot be separated by horticultural characters, and *Dendrocalamus* is hardly separable except by its great size. It is probable that many of the forms now classed as species of *Bambusa* will eventually be found to belong to other genera, especially to *Arundinaria*. Extended information regarding the *Bambuseæ* may be found in the following publications: Munro's Monograph, in Transactions of the Linnean Society, Vol. XXVI (1868); Hackel, in *Die Natürlichen Pflanzenfamilien*, Vol. II, part 2, p. 89 (1887), English Translation by Lamson-Scribner & Southworth, as *The True Grasses*, New York, 1890; papers by Bean in *Gardeners' Chronicle* III, 15:167, et seq. (1894); Freeman-Mitford, *The Bamboo Garden*, 1896, New York, The Macmillan Company, pp. 224; A. & C. Rivière, *Les Bambous*, Paris, 1879; Gamble, *The Bambuseæ of British India*, Calcutta and London, 1896; Houzeau, *Le Bambou*, Mons., 1906; Fairchild, *Japanese Bamboos*, 1903; Franceschi, *Bamboos in California*, Santa Barbara, 1908. Among the hardest of the bamboos are the following: *Phyllostachys Henonis*, *P. nigra*, *P. viridi-glaucescens*; *Arundinaria macrosperma*, *A. japonica*, *A. nitida*; *Bambusa palmata*, *B. tessellata* and *B. pygmæa*.

The list of descriptions contains the important kinds of bamboos in cultivation in America, and following the classified descriptions will be found a list of species, showing those that are more or less rare in gardens, but procurable from time to time through horticultural catalogues or prominent growers. An attempt has been made to separate the harder forms of bamboos from the tenderer kinds by the character of the venation of the leaves, a distinction that has been enthusiastically entertained by Freeman-Mitford in his most estimable work, a book that has done much to create a popular appreciation of bamboos, and also to clear up the complete confusion into which the trade names have fallen.

Bamboos have slowly but persistently increased in popular esteem, especially in the southern and Pacific states, where they have proved their great beauty and usefulness as garden ornamentals. A new impetus has been given the cultivation of these plants by the dissemination of suitable species and varieties, and by the introduction of new and desirable kinds by commercial horticulturists and the U. S. Department of Agriculture.

In the following taxonomy, A.=*Arundinaria*; B.=*Bambusa*; D.=*Dendrocalamus*; P.=*Phyllostachys*; T.=*Thamnocalamus*, which is here considered a subgenus of *Arundinaria*. No Japanese native names are indicated, although bamboos are sometimes offered under such names. The prevailing tendency is to discard vernacular names, when unassociated with the Latin binomials, as they breed hopeless confusion.

SECTION I.—Venation conspicuously tessellate, i.e., the veins crossing one another like the meshes of a net, visible to the naked eye by holding a lf. up to the light, or more clearly seen by the use of a lens. (Embraces the hardier types of bamboos, 1-30.)

A. Internodes not flattened: sheaths persistent.

B. Lvs. relatively very broad, usually 2 in. wide, or more.

1. *A. Veitchii*, N. E. Br. (*Bambusa Veitchii*, Carr.). Fig. 487. Height usually 3 ft. or less: sts. purple, white-waxy below the nodes: lvs. 5-8 in. long, about 2 in. wide, bright green above, below pale and minutely pubescent, serrate. Japan. M. 77, but not G.C. III. 15:169, or R.B. 23, p. 270, which are pictures of *B. palmata*, as explained in G.C. III. 15:209.—This is also liable to confusion with *B. tessellata*, but may be separated by lf. characters. Quite hardy, but the edges of the lvs. wither in late autumn, giving a variegated but injured appearance.

2. *B. palmata*, Burbidge. Fig. 488. Height 2-5 ft.: lvs. 10-15 in. long, 2-3½ in. wide, bright green, serrate, smooth and shining above, below pale and minutely pubescent; longitudinal veins very prominent. Japan. M. 79. Gn. 49, p. 59, shows a clump 36 ft. in circum.—A beautiful, broad-lvd. ornamental.

456. *Bambusa tessellata*. ( $\times \frac{1}{10}$ )

3. *B. tessellata*, Munro (*B. Ragamowskii*, Hort.). Fig. 456. Height 3-4 ft.: lvs. 12-18 in. long, 2-4 in. wide, smooth and shining above, whitened beneath, sharply serrate; midrib prominent and bearing a tomentose line on one side. China and Japan. G.C. III. 15:167; 18:189. R.B. 23, p. 269.—Produces the largest lvs. of any of the hardy bamboos in cult., which is especially remarkable on account of its dwarf habit. Much confused in gardens, but unnecessarily, with *A. Veitchii*, as the tomentose line on one side of the midrib is unique in *B. tessellata*. The lvs. are used by the Chinese for wrapping tea.

BB. Lvs. distinctly narrower.

c. Foliage green.

D. Plants low, usually 1-3 ft. in height.

E. Arrangement of lvs. distichous.

4. *B. disticha*, Mitford (*B. nana*, Hort., not Roxbg.). Height 2-3 ft.: sts. zigzag, slender, green or tinged with purple: branches borne singly: lvs. 2-2½ in. long, ½ in. wide, or less, green, serrate on both edges, produced in 2 vertical ranks. Origin uncertain.—An interesting and beautiful species, the distichous arrangement of the lvs. lending a distinct and unusual character.

EE. Arrangement of lvs. not distichous.

5. *B. pygmæa*, Miq. Height ½-1 ft.: sts. very slender, purple, much branched; nodes prominent, with a waxy glaucous band: lvs. 3-4 in. long, about ½ in. wide, serrate, pubescent, bright green above, glaucous beneath. Japan.—The smallest of the bamboos, and remarkably hardy. It is especially valuable as an undergrowth, quickly making a carpet in wild places; but its rampant growth will quickly outgrow close quarters.

6. *A. pumila*, Mitford (*B. pumila*, Hort.). Height 1–2 ft.: sts. very slender, purplish, white-waxy below the nodes: lvs. 4–5 in. long,  $\frac{3}{4}$  in. or less wide, minutely pubescent, bright green.—Much rarer than *B. Veitchii*, dwarfier, the sts. merely purplish, the lvs. shorter and narrower. The lvs. are a darker green than in *A. humilis*, shorter, narrower, and taper less gradually; nodes less well defined, but having a waxy bloom; internodes about  $2\frac{1}{2}$  in. long.

457. *Arundinaria nitida*. ( $\times \frac{1}{2}$ )

7. *A. humilis*, Mitford (*A. Fortunei* var. *viridis*, Hort.). Height 2–3 ft.: branches in 2's and 3's, long in proportion to the sts.: lvs. 4–6 in. long, the largest about  $\frac{7}{8}$  in. wide, pale green: internodes 2–5 in. long. Japan.—A rare and pretty plant, liable to confusion with *A. pumila*, but the sts. lack the waxy bloom of that species.

DD. Plants taller than in D, usually in excess of 3 ft.

E. Sts. hollow, cylindrical, or nearly so.

F. Culms purple, or purplish.

8. *A. nifida*, Mitford. Fig. 457. Height 6–10 ft.:

sts. slender, seldom exceeding a lead-pencil in thickness, black-purple in color: lvs. 2–3 in. long,  $\frac{1}{2}$  in. wide, shining green above, pale beneath; sheaths purplish, the ligule without hairs. China. M. 73. G.C. III. 18:179; 24:211. Gn. 49, p. 388.—One of the daintiest and most attractive of the arundinarias, and exceptionally hardy. Some shade is desirable, as the lvs. are often injured by strong sun. Easily distinguished from *A. Veitchii* and *A. pumila* by the deeper color of the sts., which are almost black.

9. *B. fastuosa*, Latour-Marliac. Height 15–20 ft.: culms marked with purple-brown: the internodes with an unusually large cavity: branches numerous, erect, giving a columnar outline to each st.: sheaths shaded with purple: lvs. 5–7 in. long, an inch or less wide, bright green above, glaucous beneath. Japan.

FF. Culms green or golden.

G. Species native.

10. *A. macrospérma*, Michx. LARGE CANE. Height 15–25 ft., with numerous, short, divergent branches: lvs. 4–8 in. or more long,  $\frac{3}{4}$ – $1\frac{1}{2}$  in. broad, smoothish or pubescent; sheaths very persistent: sts. erect, rigid, simple or sparingly branched the first year, becoming dense and leafy the second, afterwards fruiting at indefinite periods, and soon after decaying. Chiefly along river banks, Va. and Ky. southward.—Forming canebrakes, sometimes of great size and density. This and the next are the only bamboos native to the U. S. Sometimes cult. as an ornamental.

11. *A. técta*, Muhl. (*A. macrospérma* var. *suffruticosa*, Munro). SMALL CANE. SWITCH CANE. SCUTCH CANE. Height 2–12 ft.: sts. slender: lvs. 3–6 in. long, 4–12 lines wide, roughish; sheath bearded at the throat. Swamps and moist soil, Md. and S. Ind. southward.—A form, perhaps specifically distinct, which may be known as var. *decidua*, common in W. N. C., has the peculiarity of dropping its lvs. every autumn, and passing the winter in a leafless state. The foliage of this deciduous cane turns yellow in autumn, drops, and in early spring the culms resume their verdure.

GA. Species not native to the U. S.

H. Branches borne singly in the axils.

12. *A. japonica*, Sieb. & Zucc. (*B. Metake*, Sieb.). Fig. 458. Height 5–10 ft.: lvs. 4–8 in. or more in length, 1–2 in. wide, smooth and shining on the upper surface, below whitened and finely pubescent; sheaths conspicuous. Japan. M. 1. G.C. III. 15:239; 18:185.—The commonest of the hardy bamboos, and readily distinguished from other tall-growing kinds of arundinarias by the large, broad lvs. and by the broad, persistent sheaths which almost permanently unwrap the canes. From *A. Simonii* it differs by the bud being a simple flattish scale, instead of a complex scaly one, and also by the less amount of waxy bloom on the sts. Particularly recommended for cities.

HH. Branches borne in dense, semi-verticillate clusters.

13. *A. Simonii*, A. & C. Rivière (*B. Simonii*, Carr. *B. viridi-striata*, Hort. *A.* and *B. Narihira*, Hort.). Height 10–20 ft.: lvs. 6–10 in. or more in length, usually less than an inch wide, sometimes striped with white, tapering to a long, fine point; mid-vein glaucous on one side toward the apex, green on the other. Himalayas, China and Japan. G.C. III. 15:301; 18:181.—A silver-variegated form is sometimes known as *B. Maximowiczii*, Hort., and *B. plicata*, Hort. B.M. 7146.—One of the tallest of the arundinarias. Very late in starting into growth. It flowers quite frequently, and does not die down entirely after blooming, as some kinds do. Resistant to drought, hardy and ultimately very vigorous and handsome.

14. *A. Hindsii*, Munro (*B. erecta*, Hort.). Height 6–10 ft.: culms straight, the branches appearing as if whorled: lvs. upright at first, varying in length up to 9 in., and about  $\frac{5}{8}$  in. wide; the veins conspicuously tessellated: internodes 3–7 in. long, waxy-white; sheaths with a few hairs, long persistent. Japan.—The erect habit of

458. *Arundinaria japonica*. ( $\times \frac{1}{5}$ )

growth is very pronounced, and it spreads with marked rapidity.

EE. *Sts. either solid or quadrangular.*

15. *B. quadrangulâris*, Fenzl. *Sts.* square, especially in older plants, 20–30 ft. tall; lvs. deep green, serrate, 6–7 in. long, about 1 in. wide, the tessellation minute. China and Japan.—A wide-spreading species, when established, and one possessing considerable hardness. New growth is produced mostly in late summer and autumn.

16. *A. marmorea*, Franceschi (*B. marmorea*, Mitford). Height 3–5 ft.: *sts.* slender, cylindrical, without a cavity; sheaths purple, marbled with gray; nodes unusually prominent, purple, with the under side bright green; internodes short, usually 1–2 in. long; lvs. 3–5 in. long, about  $\frac{1}{2}$  in. wide, abruptly and sharply pointed at the apex. Japan.—In cult. for several years in Calif.

CC. *Foliage variegated.*

D. *Plants low, usually 1–3 ft. in height.*

17. *A. Fôrtunei*, A. & C. Rivière (*B. Fôrtunei*, Van Houtte, and var. *variegata*, Hort.). Fig. 459. Height 1–3 ft.: lvs. 4–5 in. long,  $\frac{1}{2}$ – $\frac{3}{4}$  in. wide, beautifully striped with white. Japan. F.S. 15:1535.—Sometimes loses its lvs. in severe winters, but quickly recovers in spring. The internodes are rarely more than an inch long. Var. *aurea*, Hort., with yellow variegation, is *A. auricoma*. Var. *viridis*, Hort.=*A. humilis*. An old favorite. Rhizomes very active, requiring considerable space.

18. *A. auricoma*, Mitford (*A.* and *B. Fôrtunei* var. *aurea*, Hort.). Height 2–3 ft.: lvs. 4–6 in. long, about an inch wide, brilliantly variegated with yellow, velvety pubescent on the lower surface, serrate, with the teeth more pronounced on one side; *sts.* purple; nodes 3–5 in. apart. Japan.—An exceedingly beautiful and meritorious ornamental of striking character.

19. *B. angustifolia*, Mitford (*B. Vilmorinii*, Hort.). Height about 1 ft.: *sts.* slender, purplish or light green, with prominent nodes; lvs. 2–4 in. long, about  $\frac{1}{4}$  in. wide, serrate, frequently variegated with white. Japan.—A dainty species, soon forming attractive clumps.

DD. *Plants taller than in D, usually in excess of 3 ft. (See also under No. 13 for A. Simonii.)*

20. *A. chrysantha*, Mitford (*B. chrysantha*, Hort.). Height 3–5 ft.: lvs. 5–7 in. long, 1 in. or less wide, nearly smooth, more or less variegated with yellow. Japan.—Not so brilliantly colored as *A. auricoma*, from which it may be readily distinguished by the prominent ribs and absence of the soft velvety pubescence from the lower surface of the lvs.

AA. *Internodes flattened on one side: sheaths early deciduous.*

B. *Sts. black or brown.*

21. *P. nigra*, Munro (*B. nigra*, Lodd.). BLACK BAMBOO. Height 10–20 ft.: *sts.* green at first, but changing to black the second year; nodes conspicuous, the upper rim nearly black, the lower edged with white; lvs. very thin, 2–6 in. long, 6–10 lines broad. China and Japan. M. 142, and frontispiece. G.C. III. 15:369; 18:185. R.B. 23, p. 268. B.M. 7994.—One of the most popular of the bamboos, markedly hardy and distinct. Var. *punctata*, Hort., has yellowish *sts.* spotted with brownish black.

22. *P. violascens*, A. & C. Rivière (*B. violascens*, Carr.). Height 10–20 ft.: *sts.* violet, almost black the first few months, changing the second year to a dingy yellow or brown; lvs. variable in size, 2–6 in. long,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. wide, the larger lvs. borne on young shoots or lower branches; they are sharply serrate, and have a well-defined purplish petiole. China and Japan.

BB. *Sts. striped with yellow and green.*

23. *P. Castillônis*, Hort. (*B. Castillônis*, Hort.). Height 10–20 ft. or more: *sts.* zigzag, striped golden yellow and green, the colors alternating at the nodes; lvs. sparingly striped with yellowish white, variable in size, usually 3–6 in. long,  $\frac{3}{4}$ – $1\frac{1}{2}$  in. wide, serrate, the teeth being especially prominent on one edge; lf.-sheaths topped by a whorl of dark brown or purple hairs. Japan.—Both beautiful and uncommon.

BBB. *Sts. green, yellow, or yellowish.*

C. *Plants tall, i.e., more than 5 ft. high.*

D. *The internodes very short at the base of the culms.*

24. *P. aurea*, A. & C. Rivière (*B. aurea*, Hort.). Height 10–15 ft.: *sts.* yellowish, often brilliant in color, the internodes at the base remarkably short; lvs. narrowed from near the base to the apex, minutely and regularly serrate on only one border, usually 2–4 in. long and  $\frac{3}{4}$  in. wide, but variable, light green, glaucous beneath; sheaths deciduous, marked with purple. China and Japan. Gn. 8:206. A.F. 5:41.—Easily recognized by the very short nodes at the base of the culms.

DD. *The internodes at the base of the culms not congested.*

E. *Outline of sts. not conspicuously zigzag.*

25. *P. mitis*, A. & C. Rivière (*B. mitis*, Hort., not Poir.). Height 20 or more ft., and said to attain 60 ft.

in its native soil: *sts.* deep green at first, eventually yellow; internodes at the base not conspicuously short; lvs. variable, usually 2–4 in. long and  $\frac{3}{4}$  in. wide, light green, serrate on only one border; sheaths deciduous, marked with purple. China and Japan. Gn. 17:44.—Readily distinguished from *P. aurea* by the long internodes at the base of the culms.

26. *P. Quiloi*, A. & C. Rivière (*B. Quiloi*, Hort. *B. Mazélie*, Hort.). Height 20 or more ft., and under favorable conditions up

to 70 ft.: *sts.* arched, green or yellowish, bearing unusually long branches; lvs. remarkably large and broad, the largest 8 in. long,  $1\frac{1}{4}$  in. wide, conspicuously serrate on one edge, dark green, often spotted with brown, very glaucous beneath; lf.-sheaths pinkish brown, deeply mottled with purple spots. China and Japan.—Rare and unusually attractive.

27. *P. Henônis*, Mitford (*B. Henônis*, Hort.). Height 10–15 ft.: *sts.* arched, bright green, eventually yellowish, the surface slightly roughened; sheaths yellow-brown, early deciduous; lvs. 2–3 in. long, a little under  $\frac{1}{2}$  in. broad, narrowed below the middle to the base, long-attenuate at the apex, bright green; lf.-sheaths often purplish, the ligule fringed with purple hairs; internodes 5–6 in. long near the base and middle of the culm, grooved with a double furrow. Japan.—Wonderfully graceful and eminently hardy.

EE. *Outline of sts. conspicuously zigzag.*

28. *P. viridi-glaucescens*, A. & C. Rivière (*B. viridi-glaucescens*, Carr.). Height 20 or more ft., and under favorable conditions up to 60 ft.: *sts.* zigzag, arched,

459. *Arundinaria Fortunei*. ( $\times \frac{1}{2}$ )

bright green at first, fading as they ripen to a dingy yellow: sheaths early deciduous, the ligule extended into fringed auricles: lvs. 3-4 in. long, about  $\frac{1}{2}$  in. wide or a little more, bright green above, whitened below. China and Japan. Gn. 7:279. G.C. III. 15:433; 18:183.—Frequent in cult. and very hardy.

29. *P. bambusoides*, Sieb. & Zucc. Height 6-10 ft.: sts. slender, zigzag, green at first, eventually yellowish: sheaths purplish, early deciduous: branches in 3's, the longest in the middle, little longer than the internodes: lvs. variable, 5-7 in. long, 1 in. or less wide, serrate, the teeth especially sharp on one edge, bright green, pale beneath. China and Japan. Gamble, Bamb. Brit. Ind. 27, t. 27.—The true plant very rare in cult.

cc. Plants low, 1-3 ft. high.

30. *P. ruscifolia*, Hort. Kew (*P. Kumasáca*, Mitford. *P. Kumasáca*, Munro. *B. ruscifolia*, Sieb. *B. viminális*, Hort.). Fig. 460. Height 1-3 ft.: sts. zigzag, dark to pale green: sheaths purple, much fringed: branches very short, not more than 1 or 2 in. long, in 3's and 4's: lvs. 2-3 in. long, about 1 in. wide, ovate in outline. Japan. G.C. III. 15:369; 18:189.—The sts. are almost solid, the tube being exceedingly small. Dwarfest species of *Phyllostachys*.

460. *Phyllostachys ruscifolia*. ( $\times \frac{1}{3}$ )

SECTION II. Venation essentially striate, i.e., the veins running in parallel lines from the base to the apex, cross veins obsolete or obscure, but usually with a number of interposed pellucid dots. (Embraces the less hardy types of bamboos, 31-41.)

A. Sts. hollow, not spiny.

B. Lvs. averaging not more than 3 in. long.

31. *A. nobilis*, Mitford. Height 15-25 ft.: lvs. 2-3 in. long, usually less than  $\frac{1}{2}$  in. wide, bright green, borne on short, purple petioles, striate-veined: sts. yellow-green, with purple-brown nodes. Probably a native of China.—A large and graceful species intro. into Calif. by Franceschi in 1896. One of the hardest of the arundinarias with striated lvs.

32. *A. debilis*, Thwaites. Height probably 5-10 ft.: sts. clustered, much branched, the nodes 2-6 in. apart, yellowish: lvs. 1-3 in. long,  $\frac{1}{2}$  in. or less wide, striate-veined. High mts. of Ceylon and the Philippines. Gamble, Bamb. Brit. Ind. 7, t. 6.—Intro. in Calif. and offered in 1910 by the Montarioso Nursery. The character of the venation would seem to imply only moderate hardness.

BB. Lvs. averaging not more than 6 in. long.

33. *A. falcateri*, Benth. (*T. falcateri*, Hook. f. *B. gracilis*, Hort., not Wall.). Height 10-15 ft.: sts. slender, bright green when young, yellow when old, the internodes sometimes white-waxy: lvs. thin, 3-4 in. long, about  $\frac{1}{2}$  in. wide, striate-veined. Himalayas. Gamble, Bamb. Brit. Ind. 20, t. 18. B.M. 7947.—Not very hardy. The lf.-sheaths are smooth, cut short at the top, without a fringe, and with an elongated ligule; while *A. falcata* has very downy lf.-sheaths, fringed with long hairs at the intersection with the lf. The serrations of the lf.-edges are more pronounced in *A. falcateri*, especially on one side.

34. *A. falcata*, Nees (*B. falcata*, Hort.). Height 10-20 ft.: lvs. 4-6 in. long, about  $\frac{1}{2}$  in. wide, light green, striate-veined: sts. slender, not exceeding  $\frac{1}{2}$  in. diam., covered with a bluish white-waxy coating when young, eventually yellow-green: sheaths downy, ciliate at the ligule. Himalayas. Gamble, Bamb. Brit. Ind. 12, t. 11 and 12.—A great many plants cult. under this name are really *A. falcateri*, a species with smooth sheaths and fringed ligules. Requires a mild climate.

BBB. Lvs. averaging more than 6 in. long.

C. Culms 15-25 ft. tall, reddish brown at maturity.

35. *A. Hookeriána*, Munro. Height 15-25 ft.: culms glaucous green when young, turning reddish brown with age: nodes prominent, with a bluish ring: lvs. 6-10 in. long,  $\frac{1}{2}$ -1  $\frac{1}{2}$  in. wide, the venation striate. Himalayas. Gamble, Bamb. Brit. Ind. 17, t. 15.—The tallest and largest species of arundinaria in cult. Intro. in Calif. by Franceschi. Not very hardy.

cc. Culms taller; giant species: sts. green or yellowish.

36. *B. vulgaris*, Schrad. FEATHERY BAMBOO. Height 20-80 ft.: sts. bright green, 4 in. diam., or more, straight at first, eventually much arched by the weight of the dense foliage: branches numerous, striate: lvs. usually 6-10 in. long, 8-15 lines wide, rough on and near the margins and on the lower surface. India. G.C. III. 25:390. Gamble, Bamb. Brit. Ind. 44, t. 49. Var. *aureo-variegata*, Hort., GOLDEN BAMBOO, has canes of a rich golden yellow color, penciled with green. —Will stand but slight frost.

37. *D. Hamiltonii*, Nees & Arn. Height up to 80 ft.: sts. 4-7 in. diam., much branched above, pubescent with white hairs when young: internodes 12-20 in. long: lvs. variable, sometimes 15 in. long, 2  $\frac{1}{2}$  in. wide, finely serrate; midrib narrow, with 6-17 nerves on either side, the nervules chiefly of pellucid glands. Himalayas. Gamble, Bamb. Brit. Ind. 85, t. 74.—The lower branches usually seated on woody knobs. Promises to become an important member of the tall bamboos in S. Calif.

38. *D. latiflorus*, Munro. Height 60-70 ft.: sts. erect and remarkably straight, 4-5 in. diam., with a large cavity: lvs. 7-10 in. long, 1-2 in. broad, long-acuminate, deep green, borne on short petioles; midrib prominent, with about 9 nerves on either side, the transverse nervules lacking or obscure. Formosa, Burma, Cochin China. Gamble, Bamb. Brit. Ind. 131, t. 117. Munro, Trans. Linn. Soc. 26:152, t. 6.—Considered one of the best of the giant bamboos in S. Calif.

39. *D. membranaceus*, Munro. Height 60-70 ft.: sts. white-

461. *Bambusa arundinacea*. ( $\times \frac{1}{6}$ )

powdery when young, smooth and bright green when older, 1-5 in. diam.: nodes prominent: internodes 9-20 in. long: sheaths with waved, hairy auricles: lvs. 5-10 in. long,  $\frac{1}{2}$ - $\frac{3}{4}$  in. wide, deep green above, pale beneath, slightly hispid. Burma, India. Gamble, Bamb. Brit. Ind. 81, t. 71.—Requires a warm, protected situation to attain full development. Intro. into Calif. in 1895 by Franceschi.

AA. *Sts. either solid or spiny.*

40. *B. arundinacea*, Retz. Fig. 461. A majestic species, often attaining a height of more than 40-60 ft.: sts. produced in dense clumps, at first green and shining, zigzag in outline, eventually straight and golden in color: branches, especially the lower, more or less spiny: lvs. 4-8 in. long,  $\frac{1}{2}$  in. or a little more wide, nearly glabrous; sheaths persistent: fls. produced at long intervals, and after perfecting seeds, the plants die. India. Gamble, Bamb. Brit. Ind. 51, t. 48.

41. *D. strictus*, Nees. Called MALE BAMBOO, on account of the solid character of the culms. Height 20-50 ft.: sts. 1-3 in. diam., solid or nearly so, glaucous green when young, yellowish when mature: nodes swollen: internodes 10-15 in.: branches long and slender, leafy: lvs. 4-10 in. long, up to  $1\frac{1}{4}$  in. wide, soft-hairy, at least when young, narrowed from near the base to the tip, the apex usually twisted; midrib prominent, with 3-6 nerves on either side, the nervules chiefly of interposed pellucid glands. India, Burma. Gamble, Bamb. Brit. Ind. 78, t. 68 and 69.

*B. agræstis*, Poir. India, Cochinchina. Adv. by Yokohama Nurs. Co.—*B. Alphonse Kérri*, Hort. A variegated form of *B. nana*, Roxbg. Young sts. striped with white and pink, older sts. yellow with broad green stripes. Tender.—*A. anceps*, Mitford. Similar to *A. nitida*, but mature sts. yellow-green or brown, and lf.-sheaths fringed with white hairs. Native of the Himalayas, at elevations between 9,000-10,000 ft.—*B. argentea*. Grows 25-35 ft. high; the dense masses of beautiful green foliage, glaucous underneath, and the hundreds of slender culms growing close together, the exterior ones bending over to all sides, combine to make this bamboo indescribably beautiful." H. Nehrling, Fla.—*B. argentea* var. *vitata*, the variegated bamboo or the blue bamboo of gardens, the taiho-chiku of the Japanese, who have grown this from time immemorial in pots, is one of the most satisfactory in Fla.; it attains the size of *B. argentea*, but its lvs. are still more blue on the under side and altogether smaller and more delicate; they are striped and edged with white." Nehrling.—*A. aristata*, Gamble. Sts. 5 ft., purplish brown: lvs. 4 in. long,  $\frac{1}{2}$  in. or less wide, narrowed to an acute apex, venation tessellate. Himalayas, where it thrives at elevations of 11,000 ft.—*B. aureo-striata*, Regel. Japan.—*P. Boryana*, Hort. By some authorities considered to be a form of *P. nigra*, but the culms are of a dull yellow color when mature, splashed here and there with purple-brown blotches, and the branches are much longer in proportion to the culms. China and Japan.—*P. flexuosa*, A. & C. Rivière. Culms 6-10 ft., dull greenish yellow when mature: lvs. similar to those of *P. viridiglaucescens*: ligules of the culm-sheaths without auricles. A comparatively small and compact ornamental. China.—*A. foliis variegatis*, Hort., is presumably A. Fortunei, the commonest low-growing, variegated arundinaria.—*"B. gracilis"*. This most beautiful small species used to be grown in gardens under the name of *A. falcata*: the lvs. are very small, arranged in a distichous way on both sides of the twigs; they have a fine emerald-green color: sts. thin and slender, the whole plant not growing taller than 10-12 ft." Nehrling.—*P. heterocycla*, Carr. A curious plant, the lower internodes of which are obliquely and alternately arranged like the scales of a tortoise, and for this reason called the "tortoise-shell bamboo." At about 1-3 ft. from the ground the nodes lose this peculiar character, and assume a regularity as in other species. In other respects this interesting bamboo does not differ much from *P. mitis*, or *P. aurea*. Japan.—*A. Khasiana*, Munro. A Himalayan species with black sts., allied to *A. falcata*. The name, however, has been misapplied to *A. nitida* and *A. nobilis*, and the true species is probably not in cult. in the U. S.—*B. Laydékerti*, Hort. Height 3-8 ft.: sts. green with a tinge of purple, verticillately branched above, the branches relatively long: lvs. 4-6 in. long,  $\frac{1}{2}$  in. or less wide, dark green, somewhat mottled in appearance. China and Japan.—*"B. macroculmis"*. Received about 15 years ago directly from Japan under the name of taisan-chiku. It is a veritable giant, growing 50-75 ft. high with large dark green lvs. and thick culms, first green, then black; old culms have a gray color: in stature this is one of the noblest of all the bamboos, and it is perfectly hardy: the sts. spring straight out of the soil like spears and when they have fully developed they bend over to all sides at their tops, so that the entire plant from a distance looks like a gigantic sheaf." Nehrling.—*P. marliacea*, Mitford. Wrinkled Bamboo. Similar to *P. Quiloi*, but the internodes at the base are very close together, not more than 1-2 in. apart, much wrinkled. Japan.—*P. nigro-punctata*, Hort. Probably a variety of *P. nigra*, under which it appears in the classified descriptions above.—*"B. nütans"*. A most exquisite bamboo grown for many years under the name of *Dendrocalamus strictus*.

which is a very different plant; grows 35-40 ft. high with a very dense growth of small green lvs, the green having a shade of blue in it; the sts. hang over to all sides, forming beautiful arches; tender; a most exquisite plant to grow on lawns or on the edge of lakes, or in the foreground of deep green magnolias." Nehrling.—*B. orientalis*, Nees. Adv. by Franceschi, Santa Barbara, Calif., who regards it as a form of *B. arundinacea*, with lvs. larger and velvety to the touch. It forms clumps quickly. E. India.—*A. racemosa*, Munro. A native of the Himalayas, growing at high altitudes: height up to 15 ft., the culms brown, very thick in proportion to height; the long and narrow lvs. are conspicuously tessellate.—*"B. scriptoria"*. A small species not growing over 6-8 ft. high, forming fine dense clumps: lvs. small, green, underneath glaucous; particularly valuable for small gardens." Nehrling.—*A. spathiflora*, Trin. Height 10-20 ft., the culms yellowish or nearly brown, slender and much branched: lvs. tessellate, 2-3 in. long, about  $\frac{1}{4}$  in. wide, acutely pointed, thin in texture. Himalayas, at altitudes of 7,000-10,000 ft.—*B. striata*, Lodd. Height 4-5 ft.: sts. striped yellow and green, as thick as the thumb; internodes 4-6 in. long: lvs. 6-8 in. long,  $\frac{1}{4}$ -1 in. broad. China. B.M. 6079, which shows a flowering specimen with conspicuous anthers, red-purple at first, and fading to lilac. Not described by Mitford. Formerly sold by Yokohama Nurs. Co.—*B. striatifolia* var. *aurea*, Hort., an abandoned trade name never recognized by botanists.—*B. stricta*, Hort., an old trade name probably not *B. stricta*, Roxbg.—*P. sulphurea*, A. & C. Rivière. Height 10-15 ft., seemingly intermediate between *P. mitis* and *P. aurea*. It is less tall than the former, and the sts. are more brightly colored than in the latter species. Japan.—*B. Thoudarsii*, Kunth. A doubtful species, considered by some botanists to be only a form of the widespread *B. vulgaris*; but, according to Franceschi, at least horticulturally distinct. Height 50-60 ft., with a diam. of culm of 4-5 in. Intermediate in outline between the erect-growing *D. latiflorus*, and the spreading or horizontally inclined *B. vulgaris*. Intro. into Calif. some 25 years ago, and in recent years reintro. by the U. S. Dept. of Agric. from S. France, where it had come from Algiers 40-45 years ago.—*B. Tulda*, Roxbg. Height up to 70 ft., the culms 4-5 in. diam., and of a remarkable gray-green color: lvs. very glaucous or the lower surface. Recently intro. by the U. S. Dept. of Agric. Bengal and Burma. Gamble, Bamb. Brit. Ind. 30, t. 29.—*B. variegata*, Sieb.—A. Fortunei.—*B. verticillata*, Hort., Franceschi. Height 15-20 ft.: sts. orange-yellow: lvs. in whorls, striped white.

Among the recent introductions of bamboos by the United States Department of Agriculture, representing two genera of much interest and rarity to the United States, are the following:

**CHUSQUËA.** A genus belonging to the subtribe Arundinarieæ, of tall, shrubby or climbing plants with the flowering branches in clusters at the joints, and comparatively small lvs. and spikelets. W. Indies and S. Amer., chiefly in the Andes.—*C. bambusoides*, Hack. A large species with small panicles exceeded by the crowded blades, 1 in. wide and about 6 in. long. Native of Brazil.—*C. quila*, Kunth. A freely branching arborescent species with numerous open panicles and distant lvs. scarcely  $\frac{1}{2}$  in. wide. Native of Chile.—*C. valdivensis*, Desv., of Chile, is a slender climbing species with naked sts. and numerous fasciated leafy flowering branches, the lvs. 3-4 in. long.—*C. abietifolia*, Griseb. A climbing species with dense tufts of short branches with lvs. less than 2 in. long and about  $\frac{1}{2}$  in. wide. Native of the W. Indies.

**OXYTENANTHERA.** A genus of the subtribe Eubambuseæ, of tall, shrubby plants from the E. Indies and Afr., characterized by long, cylindrical or conical spikelets in compact fascicles; the anthers enclosed in a bristle.—*O. abyssinica*, Munro (*Bambusa abyssinica*, Rich.). Infl. capitate, large and spiny: lvs. about 6 in. long, 6-8 lines broad. Native of Trop. Afr.

C. D. BEADLE.

**BAMBURÁNTA** (*Bambusa* and *Maranta*). *Zingiberaceæ*. A name applied to an undetermined plant with maranta-like leaves and bamboo-like habit, from the Congo Free State. *B. Arnoldiana*, Lind. Lvs. broadly ovate, acuminate, distinctly petioled, on long, spreading, graceful stems; attractive as a pot-plant. G.C. III. 28: 313 (1900).

**BANANA**, a name applied to certain species of *Musa*, particularly to those that produce edible fruits, although it is sometimes used for species grown for ornament, as for *Musa Ensete*. There are three groups of edible bananas. The common banana, eaten raw, *Musa sapientum*; the plantain, fruits to be cooked, *M. paradisiaca*; dwarf, with edible fruits, *M. Cavendishii*. The first two are probably forms of

462. Tip of flower-cluster of banana.

one species, and the botanical nomenclature is confused. Some species produce fiber. Consult *Abaca* and *Musa*.

The banana plant is a great perennial herb. It grows 10 to even 30 feet tall, and produces a bunch of fruit, and the stalk then dies or becomes weak; in the

463. Plantain banana. ( $\times \frac{1}{5}$ )

meantime, suckers have arisen from the rootstock to take its place. The peculiar flower-bearing of the banana is shown in Fig. 462, which illustrates the tip of a flower-cluster. This cluster may be likened to a giant elongating bud, with large, tightly overlapping scales or bracts. Three of these bracts are shown at *a a a*, in different stages of the flowering. As they rise or open, the

flowers below them expand. The bracts soon fall. The flowers soon shed their envelopes, but the styles, *b*, persist for a time. The ovaries soon swell into bananas, *c*. The bracts are royal purple and showy.

The banana has come to be one of the most popular fruits in North America, due to the cheapness of its cultivation and transportation, ease of handling, long-keeping qualities, and adaptability to many uses. The source of supply is mostly Jamaica, Costa Rica, Cuba, Honduras, and latterly the northern shores of Colombia. In the tropics, the ordinary bananas are cooked and used as a vegetable rather more than as a fruit to be eaten from the hand. The plantains, which are coarser and harder fruits and thicker, are always cooked. A form of cooking banana used in parts of tropical America is shown in Fig. 463. Of the banana itself there are many varieties. The common large fruit in northern markets is the Martinique, Jamaica, Gros Michel or Bluefields. A red variety, the Baraço or Red Jamaica, is sometimes seen. In the tropics, various very small forms are grown for local consumption. These are fragile and do not keep long, and are rarely seen in the markets North. One of them, known as the "fig" in Trinidad, is shown in Fig. 464; the fruits are about 3 inches long. The dwarf or Cavendish banana is grown extensively in the Canary Islands, and apparently also in Bermuda; and it is not uncommon as an ornamental plant in conservatories.

It is said that the banana was first imported into the United States in 1804 by Captain John N. Chester of the schooner *Reynard*, the lot consisting of thirty bunches. The first full cargo is said to have been 1,500 bunches brought to New York in 1830 on the schooner *Harriet Smith*, chartered by John Pearsall of the firm of J. & T. Pearsall. Two or three cargoes would appear each year, until about 1857 William C. Bliss entered the

banana-importing business, securing his supply from Baraço, Cuba, and taking the trade to Boston. In 1869, he secured a small cargo from Jamaica. In recent years, the Jamaica-United States banana trade has assumed very large proportions.

464. A hand of the "fig" banana. ( $\times \frac{1}{10}$ )

In the United States, there is little commercial cultivation of bananas, since the frostless zone is narrow and the fruit can be grown so much more cheaply in Central America and the West Indies. Small banana plantations are common in southern Florida, however, and even as far north as Jacksonville. They are also grown in extreme southern Louisiana, and southwestward to the Pacific coast. The plants will endure a slight frost without injury. A frost of five or six degrees will kill the leaves, but if the plants are nearly full grown at the time, new foliage may appear and fruit may form. If the entire top is killed, new suckers will spring up and bear fruit the following year. A stalk, or trunk, bears but once; but the new sprouts which arise from the roots of the same plant continue the fruit-bearing. A strong sprout should bear when twelve to eighteen months old (from two to three years in hothouses).

465. A bearing banana plant.

The plantation will, therefore, continue to bear for many years. A bearing stalk, as grown in southern California, is shown in Fig. 465.

The species mostly in demand for fruiting seldom or never produce seeds, and naturally increase by suckers. The suckers are most readily separated from the parent rootstock by a spade. This is a slow process of increase, but the suckers so produced make large and vigorous plants. A quicker method of propagation is to cut the entire rootstock into small, wedge-shaped pieces, leaving the outer surface of the root about 1 by 2 inches in size, planting in light, moist soil, with the point of the wedge down and the outer surface but slightly covered. The best material for covering these small pieces is fine peat, old leaf-mold, mixed moss and sand, or other light material that is easily kept moist. The beds so planted should be in full open sunshine if in a tropical climate, or given bottom heat and plenty of light if in the plant-house. The small plants from root-cuttings should not be allowed to remain in the original bed longer than is necessary to mature one or two leaves, as that treatment would stunt them.

The textile and ornamental species, also, may be increased by the above process, but as these species usually produce seeds freely, seedlings can be more quickly grown, and with less trouble. The seeds of bananas should be sown as fresh as possible, treating them the same as recommended for root-cuttings. As soon as the seedlings show their first leaves, they should be transplanted into well-prepared beds of rich, moist soil, or potted off and plunged into slight bottom heat, as the needs of the grower or his location may demand. Both seedlings and root-cuttings should have proper transplanting, sufficient room and rich soil, as a rapid, unchecked growth gives the best and quickest results.

In the West Indies, Central America and Mexico, bananas are raised for export to the United States and Canada. The site chosen is usually a level plain in the lowlands, near the coast, or in valleys among the hills, where the rainfall or artificial moisture is sufficient. For distant shipping, bunches of fruit are cut with "machetes" or knives, after they reach their full size and are almost mature, but quite green in color. Ripening is effected during shipment in warm weather, and by storing in dark, artificially heated rooms during cold weather. Banana flour is a valuable product of ripe bananas prepared among the plantations in the tropics. It is nutritious, and has an increasing demand and use as human food. A recently invented process of drying ripe bananas has been found very successful, and the industry promises to be of vast importance as the marketable article finds ready sale. Further details of the growing of the commercial crop in the tropics may be found in *Cyclo. Amer. Agric.*, Vol. II, p. 199.

E. N. REASONER.  
L. H. B.

**BANEBERRY:** *Actæa*.

**BANKS.** The means of holding and planting banks and steep surfaces is one of the perplexities of the horticulturist and landscape designer. The banks to be considered may be defined as very steep earth slopes with a bare, shifting surface, requiring protection and planting, or a surface covered with natural vegetation. Figs. 466-469.

Low banks, either curved or rigidly formal, usually enter into symmetrical designs of the elaborately finished surroundings of a fine home. Usually they are

466. A bank before planting.

placed to outline or to inclose parts of a design, or to decrease or increase the apparent height of a building or other structure, or of a garden compartment.

#### Protection.

One problem to be solved is the protection of sea, lake, river, and small stream banks and bluffs against the sliding of the soil, due to waves or along-shore currents in sea or lakes and to running water, especially

floods, in stream beds. Such water-action, cutting under the base of a bank, causes the soil above to slide down. On lake and sea shores, jetties built from the bluff-base into the water will check an eroding marginal current, make it drop its load of silt, and extend the shore. In many positions willows, planted close together in a wide band on the beach or at the bluff-base, will accumulate and fill with roots the soil that

467. Same bank after planting.

is washed down and blown in, and thus create a water-resisting barrier. Along salt water, plantations of the sea-beach grass, *Ammophila arenaria*, and the shrubby *Baccharis halimifolia* and *Iva frutescens* are serviceable; and far South, the mangrove may be planted on outermost sea-edges.

Another bank trouble is soil-seepage water coming to the surface part way up the slope and making mud patches that slide down and cause the soil above to cave away. Usually this sloughing is at an impervious soil layer at some feet below the surface, to which the water passes, then finds its way out to the bank-face. If this water is at fixed spring-like points, a tile drain laid in porous material about 3 or 4 feet deep and directly down the bank to a concrete anchor at the outlet opening will usually take off the water that causes sliding. If the seepage is all along the face of the bank, it may be necessary to carry a drain some feet back from and parallel to the edge of the bluff-top down to and a little into the impervious soil, with tile outlets down the bank.

The surface of banks is often gullied by water running from the top down the face at frequent intervals. This may be prevented by forming a ridge or barrier at the edge of the bluff to carry the water along sodded channels to paved or piped outlets down the slope.

Sand-bluff surfaces that drift with the wind need thick plantations of plants that will grow well in sand, with a mulching of hay, leaves or litter to keep the sand in place until vegetation is established.

The erosion of large streams at the base of bluffs is often beyond the means of individuals to control, although persistent willow-planting along shore and planting on the slope, will often suffice. In bad banks, a riprap of stone with plants having matted roots between the stones will hold. On smaller streams, ripraps of stones or stumps, while unattractive until covered with vines, will hold banks at critical places. A continuous stone wall is not a good barrier unless it is high enough on both sides to include flood-water, and the cost of such walls is too high for most individuals.

On sliding slopes there is usually an overhanging upper edge with a short perpendicular edge just under it to be graded back. The material thus secured may be used at the foot of the bluff. When more ideal conditions are desired, the grading may be extended to give angular raw banks the graceful contours that nature's gradual rounding-down of angles will give

### Planting.

On low banks and terraces, where soil may be thoroughly prepared and well cared for, turf or any vigorous plant can be established. In elaborate garden designs, such planting is often trimmed or trained to a uniform surface or arranged to make a part of a formal pattern.

On high banks, landscape beauty of distinction may be created by the selection, arrangement and manage-

468. Banks held by moderate planting, the scenic features not being obscured.

ment of artificial plantations or the natural growth. High banks uniformly drained and graded to prevent slipping, such as railroad and reservoir slopes, may be turfed. Such treatment is not recommended in large operations in which an interesting and varied surface-cover, or a low maintenance cost, is desired. When large bluffs require many thousand plants and limitations of cost require that they be planted with little soil preparation, varieties must be selected that will grow well in the soil presented. They must be plants that can be procured in large quantities at low cost, for the bulk of the planting, and it is desirable that they have such special characteristics as underground or surface stolons or trailing stems that root strongly at frequent intervals, or stems that root at the tips. There are also varieties with very densely matted fibrous roots that hold soil well.

The following plants meet these requirements for the soils indicated:

Low evergreen plants for the sandy or gravelly soil of the North: Bearberry (*Arctostaphylos Uva-Ursi*) an ideal evergreen trailing ground-cover for sand or gravel, of which collected plants must be used that are not easily transplanted. Trailing juniper (*Juniperus communis*). Savin juniper (*Juniperus Sabina*). These three species are not procurable in large quantities at low cost, and collected plants do not transplant readily.

Low evergreen plants for good soil in shade: Evergreen spurge (*Pachysandra terminalis*), excellent for shade and hardy over a wide territory. Myrtle or large periwinkle (*Vinca major*), from Virginia south. Periwinkle (*Vinca minor*), from Pennsylvania north. The last three plants are offered by nurseries in large quantities, the latter at low cost by collectors, and collected plants transplant well. Japanese evergreen honeysuckle (*Lonicera japonica*). This climber and trailer is one of the best bank-covers in states south of New York, and it can be obtained in nurseries or from collectors in large quantities. Spring planting should be done very early.

For low deciduous trailers or medium high shrubs for nearly all soils, the tip-rooting species of blackberry, such as *Rubus canadensis*, *R. dumetorum*, *R. occidentalis*, and the species with underground stolons, such as the cultivated high-bush blackberries, and red raspberries, are serviceable and can be obtained in large quantities at low cost. Plants having a similar habit may also be thus secured, as the matrimony vine, the Indian

currant, the weeping golden bell (*Forsythia suspensa*), the wild roses, (*Rosa lucida* or *R. nitida*), the staghorn sumac (*Rhus typhina*). Of low-cost trees, the common locust, soft maple, box elder, and Russian mulberry, are all suitable.

Of matted-root plants, the Japanese barberry, the hop-tree (*Ptelea trifoliata*), the European euonymus, the common buckthorn, can usually be readily procured.

Of small trees for shade, the flowering dogwood and red-bud are especially suitable and attractive from Massachusetts and New York south.

Of tall evergreen trees, the white pine is more serviceable for light soils and more easily procured; the arborvitæ and red cedar are the most available medium-height trees for average soils.

In California, the mesembryanthemums are largely used for bank-covers.

It is very desirable to establish a ground-cover of low shrubs and especially herbs under trees on banks as soon as practicable. By using hay containing wild asters, thoroughworts, blazing star, goldenrod, perennial sunflowers, and the like, for mulching young plantations, many of these plants will be introduced from seed, especially when seeds are mature. These will gradually be superseded by such shade-loving plants as ferns, violets, woodland asters, and goldenrods, especially if colonies of these plants are introduced as soon as the plantations are high enough to give shade.

### Arrangement.

If it is important to retain an extended open view from the top of high banks, then high trees must be confined to the lower edge, medium-sized trees and large shrubs to the central zone, and trailing plants or low shrubs to the upper zone. If the bank is a low one, then low trees or large shrubs must be substituted for the large trees at the bottom of the bank. It is often more interesting, however, to allow the bank to be covered with tall trees and then open vistas and views through these trees

by cutting branches and thinning out as they develop. Banks offer rather an unusual opportunity for the development of interesting detail in the development of the planting, because of varying conditions of moisture and soil. Such interesting details should be made accessible by trails following along the slope on easy grades that can be made at the time the bank is first graded or at later periods as the growth develops.

469. Flat plan of a bank treatment on the right of the plan; and good planting against the residence, and up a bank at the rear.

WARREN H. MANNING.

**BANKSIA** (Sir Joseph Banks, 1743-1820, famous English scientist). *Proteaceæ*. Australian evergreen shrubs or trees with handsome foliage, but not widely known in cultivation here.

Leaves variable, often deeply incised, usually dark green above, white or brown downy beneath; fls. showy, sessile, usually in pairs, spicate; spike terminal or axillary, mostly crowded within the bracts and floral lvs.,

the pistillate ones ultimately forming thick woody strobiles.—Species 46, more than 23 of which have been more or less cult. in England, but only 2 or 3 so far known here.

Propagation is difficult, and by seeds is usually an unsatisfactory method, although *B. serrata* has been grown satisfactorily from seeds. Cuttings under a bell-jar, without too much heat, root fairly well.

The following have been recently catalogued in North America; none of them has "gained a permanent foothold" in California. Several species are known in American botanic gardens.

**integrifolia**, Linn. Ten to 12 ft.: lvs. 6 in. long, 1-1½ in. wide, entire, or rarely a little dentate, the upper side dark green, silvery white beneath, scattered or sometimes irregularly verticillate; spikes 3-6 in. long; perianth about 1 in. long, greenish yellow. Cav. Ic. 546. B. M. 2770. Lam. Encyc. 54.

**serrata**, Linn. Tree, 10-20 ft., the young branches tomentose: lvs. oblong-lanceolate, 3-6 in. long, coriaceous and deeply and regularly serrate: fls. similar to the preceding, but red. B. R. 1316 (as *B. undulata*). Cav. Ic. 539, 540.—Almost perfectly hardy in Cent. Fla.

**ericifolia**, Linn. Fig. 470. Shrub or small tree, 12-14 ft.: lvs. scarcely longer than ¾ in., heath-like: spikes 6-10 in. long, the yellow perianth about ¾ in. long. B. M. 738. Andr. Bot. Rep., pl. 156. Cav. Ic. 538.

*B. latifolia*, R. Br. Stout shrub: lvs. irregularly almost spiny serrate, 4-8 in. long, 1½-3 in. wide: spikes 3-5 in. long; perianth slender, scarcely 1 in. long, greenish. B. M. 2406.—*B. prionotes*, Lindl. Tree, 15-25 ft.: lvs. 8-11 in. long, ½-1 in. wide, pinnatifid: spikes 3-5 in. long; perianth scarcely an inch long, villous; style rigid, incurved at the base.

N. TAYLOR.

**BANUCALAG**: *Aleurites trisperma*.

**BANYAN TREE**: *Ficus indica*, and other species.

**BAOBAB**: *Adansonia*.

**BÁPHIA** (name meaning *dye*). *Leguminosæ*. CAMWOOD. BARWOOD. Shrubs or small trees, sparingly planted far south.

Erect or climbing: lvs. 1-foliate, exstipellate, the stipules small: fls. white or yellow, papilionaceous, fascicled or racemose; calyx short-toothed but becoming slit as the fl. opens; standard orbicular, and wings oblong or obovate, keel obtuse and slightly incurved; stamens not united: pod linear-lanceolate, acuminate, flattened.—A dozen species in Trop. Afr. and Madagascar. Sometimes grown in hothouses. Prop. by cuttings bearing lvs.

**racemosa**, Hochst. Erect, 8 ft., branches glabrous: lvs. leathery, 3 in. long, oblong or nearly so, acute: fls. large in a leafy panicle; corolla much exceeding the calyx, white with purple veins on the standard: pod 2 in. long, about 2-seeded. S. Cent. Afr. and Natal.—Offered in S. Fla.

L. H. B.

**EAPTÍSIA** (Greek, *to dye*, alluding to the coloring matter in some species). *Leguminosæ*. FALSE INDIGO. About twenty-five erect perennial herbs of eastern North America, sometimes planted in borders and collections.

Branching herbs: lvs. alternate, mostly 3-foliate: corolla papilionaceous, the standard not larger than the wings: calyx campanulate, the 5 teeth separate and equal or the 2 upper ones united: stamens 10, distinct:

470. *Banksia ericifolia*.  
(× ½)

pod stalked in the calyx.—Plants usually turn black in drying.

Baptisia thrive in any ordinary soil and under common treatment, preferring free exposure to sun. Propagation is by division or seeds.

A. *Lf.-blades simple: fls. yellow.*

**simplicifolia**, Croom. Branchy, 2-3 ft.: lvs. 2-4 in. long, sessile, broadly ovate and obtuse: fls. in numerous terminal racemes. Fla., in dry pine- or oak-lands.—Intro. 1891.

**perfoliata**, R. Br., with small axillary fls. and broad perfoliate lvs., is occasionally planted, and is hardy as far north as Washington, but is evidently not in the trade. S. C. and Ga., on sand-hills. B. M. 3121.

AA. *Lf.-blades compound, 3-foliate.*

B. *Fls. yellow.*

**tinctoria**, R. Br. WILD INDIGO. Bushy-branched 2-4 ft., glabrous: lvs. stalked, the lfts. small, obovate or oblanceolate, and nearly or quite sessile and entire: fls. ½ in. long, bright yellow, in numerous few-fl. racemes. Common in eastern states and to La. B. M. 1099. Mn. 5:81.—A kind of indigo may be extracted from this plant, and it has been used by dyers. The root and sometimes the herb are employed medicinally.

**lanceolata**, Ell. About 2 ft., pubescent when young, but becoming nearly glabrous: lvs. short-stalked, the lfts. thick, lanceolate to obovate and obtuse: fls. large, dull yellow, axillary and solitary but close together near ends of branches. Pine barrens, N. C. to Fla.

BB. *Fls. blue.*

**australis**, R. Br. (*B. cærulea*, Eaton & Wright. *B. exaltata*, Sweet). Stout, 4-6 ft., glabrous: lvs. short-stalked; lfts. oblanceolate to oval, entire, obtuse: fls. lupine-like, indigo-blue, nearly or quite an inch long, in loose-fl. long terminal racemes. Pa., W. and S. J. H. III. 29:64; 34:511.—Handsome. Probably the best species for cult.

BBB. *Fls. white or whitish.*

**alba**, R. Br. Wide-branching, 1-3 ft., smooth: lvs. stalked; lfts. oblong or lanceolate, obtuse, thin, drying green: fls. white, ½ in. long, in long-peduncled, elongated lateral racemes. N. C., W. and S., and extending northward. B. M. 1177.

**leucantha**, Torr. & Gray. Branching, more or less succulent, 2-4 ft., glabrous: lvs. stalked; lfts. obovate to oblanceolate to cuneate, very obtuse, drying black: fls. white, nearly an inch long, in loose-fl., lateral racemes. Ont. to Texas.

**leucophæa**, Nutt. St. stout and angled, but low and wide-branched, 1-2½ ft., hairy or nearly glabrous: lvs. short petioled; lfts. oblanceolate to obovate, stiff, drying black: fls. large and cream-colored, on slender erect pedicels, borne in 1-sided declined racemes. Mich. to Texas. B. M. 5900. Mn. 3:177. F. S. 23:2449.

L. H. B.

**BARBACÈNIA** (Barbacena, a Brazilian governor). *Amaryllidacæ*. About 30 Brazilian plants, with scape bearing a single purple fl. Grown mostly in baskets, after the manner of many orchids. *B. purpurea*, Hook., is occasionally seen in fine collections, but does not appear to be in the American trade. Grown in a warm, moist house. It has many scapes which are much longer than the long, grass-like, toothed, prominently keeled lvs; 1½ ft. Summer. B. M. 2777.—The genus is anomalous. It has been placed in the *Hæmodoracæ* as well as in *Amaryllidacæ*; and Engler & Prantl place it in the small family *Velloziacæ*.

**BARBADOS LILY**: *Hippeastrum*.

**BARBARÈA** (from the old name, Herb of Saint Barbara). *Cruciferae*. Hardy biennials, with yellow flowers, sometimes cultivated; allied to water-cress and horse-radish.

Branching leafy herbs: fls. small, yellow, clustered: fr. a linear cylindrical and 4-angled pod, the valves keeled.

*vulgaris*, R. Br. COMMON WINTER CRESS. UPLAND CRESS. YELLOW ROCKET. Fig. 471. Height 10-18 in.: lower lvs. lyrate, the terminal lobe round, the lateral usually 1-4 pairs; upper lvs. obovate, cut-toothed at the base. Eu. Asia.—Cult. for salad, and also a common weed, making fields sulfur-yellow in early spring. Native far N., but apparently a settler in central states. Var. *variegata*, Hort., lvs. splashed and mottled with yellow, is cult. as a border plant, and grows freely in rich soil. If the fls. are picked off, st. and all, before they open, the plant will be practically perennial.

*præcox*, R. Br. (*B. verna*, Asch.). EARLY WINTER, or BELL ISLE CRESS. Distinguished by the more numerous divisions of the lvs. (4-8 pairs) and thickened pedicels. Slightly cult. as a winter salad, and known S. as scurvy grass. Naturalized from Eu.

**BARBE DE CAPUCIN:** *Chicory*.

**BARBERRY:** *Berberis*.

**BARBIÈRIA** (after J. B. G. Barbier, French physician). *Leguminosæ*. Hothouse evergreen; 1 species, from Trop. Amer. Its nearest allies familiar to the horticulturist are *Indigofera* and *Petalostemon*. It is distinguished from these allied genera by the calyx- and corolla-tubes, which are much longer than in either of them. Tender evergreen shrubs, with odd-pinnate lvs., numerous entire lfts., and awl-shaped stipules: fls. large racemose, red. Prop. by seed and by cuttings of half-ripened wood under a bell-jar, with bottom heat.

*pinnata*, Baill. (*B. polyphylla*, DC. *Galactia pinnata*, Pers. *Clitorea polyphylla*, Poir.). Lfts. 9-11 pairs, elliptic-oblong, mucronate, pubescent with age: racemes few-flld., shorter than the lvs.; fls. 2 in. long. Trop. Amer.—*B. glabellula*, Hort., is probably a variety. N. TAYLOR.†

**BARKÈRIA:** *Epidendrum*.

**BARLÈRIA** (J. Barrelier, died 1673, French botanist). *Acanthaceæ*. Hothouse evergreen shrubs.

Fls. axillary or terminal, the calyx with 4 sepals, the 2 outer larger than the inner; corolla-tube long, its limb of 5 rounded, ovate lobes.—A genus of 150 species of tropical shrubs, mostly African, sometimes seen in fine col-

lections of stove plants, but not offered in the American trade. Prop. by cuttings of young wood, under a bell-jar with bottom heat. *B. cristata*, Linn., with purplish blue fls., or rarely white, in dense spikes, is sometimes used as a bedding plant. *B. strigosa*, Willd., with subcoriaceous lvs., somewhat strigose, and large blue fls. in terminal spikes, is not uncommon in botanic garden collections.—Worthy of greater notice.

N. TAYLOR.

**BARLEY.** Various kinds of *Hordeum* of the *Gramineæ*. Common barley is *H. sativum*, Jess. According to Hackel, it "undoubtedly originated from *H. spontaneum*, C. Koch, which grows wild from Asia Minor and Caucasian countries to Persia and Beloochistan, as well as in Syria, Palestine, and Arabia Petraea." The common barley has a 4-rowed ear or head. There are also 2-rowed and 6-rowed races, and other well-marked forms. They are probably all domestic forms of one parent stock. For fuller treatment, see *Cyclo. Amer. Agric.*, Vol. II, p. 202.

**BARÓSMA** (*heavy scent*). *Rutaceæ*. A group of 15 species of S. African heath-like shrubs. Fls. on axillary twigs; calyx 5-cleft or 5-parted; petals 5, oblong, usually subsessile; stamens 5, alternating with 5 staminoidea: lvs. mostly opposite, rarely in 3's. Some of the species furnish the buchu lvs. of commerce, which are used in medicine for their diuretic, diaphoretic, stimulant, and tonic properties. They are evergreens, and in the N. must be grown under glass. Prop. by mature-wood cuttings.

*pulchella*, Bartl. & Wendl. Fig. 472. Shrubby, 3-4 ft.: lvs. scattered, ovate, with a revolute margin: fls. axillary, solitary or in pairs longer than the lf.; petals 3 times longer than the calyx. B.M. 1357 (as *Diosma*).—Sold by some dealers, but rare in this country.

*B. fatidissima*, Bartl. & Wendl. (*Agathosma fetidissima*, Hort.). A low shrub, 2-3 ft.: lvs. ternate, a little longer than the internodes: fls. umbellate at the ends of the branches, the petals one-half to one-third longer than the calyx, white or pinkish white.—Attractive little shrub, grown in the temperate house, but evil-smelling. It often scents a whole greenhouse.

N. TAYLOR.

**BARRINGTONIA** (Daines Barrington, English naturalist and antiquary, died 1800). Including *Stravidium*. *Myrtaceæ*; placed in *Lecythydaceæ* by those who keep this group as a distinct family. Evergreen broad-leaved trees, some of which are planted in the tropics for the striking foliage and flowers.

Leaves mostly large and crowded at the ends of the branches, entire or somewhat crenate: fls. large in the cult. species and striking because of the numerous long and protruding stamens which are united in a ring; calyx-tube ovoid or turbinate, lobed; petals 4 or 5; ovary inferior, 2-4-celled: fr. a fibrous berry-like or box-like structure, crowned by the calyx-limb, 1-seeded by abortion of other ovules.—About 30 species in tropical parts of Asia, Afr., and Polynesia, bearing the white or reddish fls. in spikes or racemes.

*speciosa*, Forst (Figs. 473, 474), is apparently most planted in parts of the American tropics: tree wide-spread-

471. *Barbarea vulgaris*.

L. H. B.†

472. *Barosma pulchella*.

473. *Barringtonia speciosa*.  
( $\times \frac{1}{2}$ )

ing, large-boled, to 50 ft. in height: lvs. entire, obovate, sessile, shining, 12-15 in. long: fls. few in the raceme, large and showy, petals white and stamens tinted purple, the style long and prominent: fr. 4-sided (almost square in cross-section at the middle or below), 3 in. diam. at base, box-like in looks, with a single large seed and crowned by calyxlobes and style. India, near the sea. L. H. B.

**BARTONIA** of Sims is *Mentzelia*; this is in cult. Bartonia of Muhlenberg is one of the Gentianaceæ, but is not cult.

**BASÉLLA** (native Malabar name). *Basellacæ*. MALABAR NIGHTSHADE. Annual or biennial herbs, cult. in the tropics as a pot-herb, like spinach. They have bisexual, white, red or violet fls. Rarely cult. N. as an ornamental warmhouse climber. It may also be started indoors, and set out in May for use as a garden vegetable, to follow spinach. Prop. by seeds. Only 1 species, which is, however, remarkably variable.

*rùbra*, Linn. Lvs. succulent, alternate, rarely opposite, almost entire, of various forms: fls. not pedicelled, in simple spikes or racemes; spikes short or long, lax, few-fl'd. Lam. Ill., pl. 215, fig. 1. Rheede, Hort. Mal. 7, pl. 24.—The following species are now considered only forms of the above: *B. alba*, a white-fl'd. form rarely cult. as a trailer from roofs of warmhouses, or as a basket plant; *B. caninifolia*; *B. cordifolia*, with heart-shaped lvs. 4-5 in. long and 2-2½ in. wide; *B. crassifolia*; *B. japonica*; *B. lucida*, from India; *B. nigra*, a Chinese form; *B. ramôsa* and *B. volubilis*. Under the name of sweet malabar vine, a form with tiny yellow and red fls., and lvs. variegated with white, pink, and green has been advertised. It is said that "with age it assumes a drooping habit. When cut, keeps fresh for weeks."

**BASIL.** Species of *Öcimum* (sometimes, but incorrectly written *Ocymum*), of the *Labiata*. They are Indian annuals, and are cult. as pot-herbs, the clove-flavored foliage being used as seasoning in soups, meats and salads. They are of easiest cult., the seed being sown in the open as soon as the weather is settled. Common basil is *Öcimum basilicum*, Linn., a foot high, branching, with ovate toothed lvs., and white, bluish white, or purplish fls. in leafy terminal racemes or spikes. *O. minimum*, Linn., the dwarf basil, is lower, and smaller in all its parts; rarely seen and perhaps only a mere form of *O. basilicum*, Linn. When basil is in bloom, it can be cut and dried for winter use.

**BASILIMA:** *Sorbaria*.

**BASKET PLANTS.** Under this term are included all those plants which, from their habit of growth and blooming and adaptabilities as to cultivation, have been found especially suitable for use in hanging-baskets. Figs. 475, 476.

Most of the basket plants are dwarfish subjects of indeterminate growth, of gracefully drooping or vine-like habit, and are valued either for their grace, or for freedom and daintiness of bloom. Some of the plants used in baskets are of upright habit. These are either plants of naturally small stature, or are practically such for a season from a slow habit of growth. The suitability of these erect-growing plants for the purpose is determined, aside from their stature, by their freedom of bloom, beauty of foliage, striking form, or grace of habit. Such plants are used principally for filling the central part of the basket; whereas, plants of trailing habit are inserted near the sides—some to droop, others to twine upward on the cords or handle by which the

basket is suspended. In addition to the long drooping or climbing plants, there are a number of half-erect habit, like the lobelia, sweet alyssum and russelia. These may droop somewhat, but are not of a truly vine-like habit. Some plants are more suitable than others for shady places; the selaginellas, are examples. Others thrive only with several hours of direct sunshine each day.

The following list of common trade names embraces a number of the most important basket plants, arranged according to habit of growth and blooming. The list is, of course, not complete. Any list would need amending from year to year to suit individual taste and experience. Plants that withstand considerable shade are marked with an asterisk (\*); those that will bear much shade are marked with two asterisks (\*\*):

## 1. Plants of vine-like habit.

### a. LONG-DROOPING.

\*\*English Ivy, \*Kenilworth Ivy, \*Vine major, \*V. Harrisoni, Saxifraga sarmentosa, \*Cissus discolor, \*Moneywort Ivy, Tropæolum (Nasturtiums), Lonicera Halliana, L. aurea var. reticulata, Nepeta Glechoma, Ampelopsis quinquefolia, A. Veitchii The ampelopsis is deciduous, and not suitable for winter baskets.

### b. CLIMBING.

Maurandia, \*\*Lygodium scandens, \*Senecio scandens, Thunbergia, Cobæa scandens, Japanese Variegated Hop, Manettia bicolor, Lonicera Halliana, L. aurea var. reticulata, Clematis coccinea, Tropæolum peregrinum, forms of Convolvulus.

### c. SHORT-DROOPING, OR HALF-ERECT.

\*Lobelia Erinus, \*Othonna crassifolia, \*Sweet Alyssum, \*Tradescantia, Petunias, Oxalis floribunda, \*Russelia juncea (also bears sun well), \*Fittonia, \*Fuchsia procumbens, Ice Plant, Verbena, \*Ivy Geranium, \*\*Selaginellas, \*Begonia glaucophylla var. scandens, \*Sedum Sieboldii, \*S. carneum var. variegatum, \*Asparagus Sprengeri, \*Passifloras, \*Panicum variegatum, Gazania splendens, Abutilon megapotamicum and var. variegatum, Lantana delicatissima, Solanum jasminoides, S. Seaforthianum, Convolvulus mauritanicus.

## 2. Plants of upright habit

### a. LOW-GROWING.

(1) *Flowering Plants.*—\*Torenia, \*Pansy, Cuphea platycentra, C. hysopifolia, \*Primula obconica, Dwarf Alyssum, Bellis perennis, Linum or Reinwardtia trigyna, Phlox Drummondii, Dutch bulbs.

(2) *Foliage Plants.*—\*Peperomia, \*Begonia Rex, \*Fartugium grande, Alternanthera, \*\*Maidenhair Fern, Geraniums (especially Mme. Sallerot), \*Isoplepis gracilis (droops with age).

### b. TALLER-GROWING.

(1) *Flowering.*—Geraniums—\*Pelargonium, \*Fuchsias, Petunias, \*Begonias, Browallia, \*Stevia serrata var. nana, Madagascar Periwinkle, \*Nierembergia, Lantana, \*Impatiens Sultana, Cuphea llavea, Swainsona, Chrysanthemum frutescens, Salvia.

(2) *Foliage.*—\*Dusty Miller, \*Crotons, \*Palms, \*\*Ferns, \*Fancy Caladiums, Coleus, Achyranthus, \*Aspidistra, \*Cyperus alternifolius, \*Dracæna indivisa, \*D. terminalis, Coccobola platyclada.

Some of the above plants make large subjects when growing in the open ground. Of such, only young or smaller plants are available for use in hanging-baskets. Ordinarily, several different sorts of plants are used for filling a basket. In some cases, however, a satisfactory basket is made by using but one kind of plant. A hanging-basket filled with sword fern (nephrolepis), for example, makes a handsome object.

The soil used in hanging-baskets is simply good, common, florists' potting soil. This usually contains about 25 per cent of humus, and a small amount of sharp sand to make it porous. Prior to filling, wire baskets must be lined with moss. This is merely common woodland moss from rotting logs, or rich, damp

474. Fruit of Barringtonia. (× 1/6)

475. A hanging-basket.

soil. In filling baskets, a few drooping or climbing plants are disposed around the sides; then one or more upright-growing or half-erect plants, according to the size of the plants and basket, are planted in the center. Immediate effects require plants which have already made considerable growth. Florists usually carry a stock of suitable plants. In case seedlings or cuttings are grown for the purpose, it is usually best to start them in seed-pans or cutting-boxes, and transfer them later to the basket. Seeds may be sown or the cuttings started in the basket, but it is so long before they fill the basket that there is no advantage in it.

A common mistake in arranging baskets is crowding, or filling them too full. Fewer plants will appear more graceful, growth will be more vigorous, and the basket will retain its grace and beauty for a longer time. Exercise vigilance and care in watering. After the roots have well filled the basket, watering is best done by dipping the basket in a tub or barrel of water, and allowing it to remain until it is well saturated. Dipping the basket in weak liquid manure once or twice a month will greatly promote vigor when the plants have been long in the basket. These remarks also apply in a general way to vases and rustic stands.

Baskets of many patterns are obtainable from florists and other dealers. The baskets most extensively used, are made of strong wire, woven into hemispherical or other forms. These are sometimes plain, and again of ornamental character. The better form has a flat bottom, or a stand, formed of wire, to support the basket in an upright position when it is not pendent. Another style is formed of rustic work. Here the vessel or plant basin is covered about the sides with rough bark or knotted roots. For this purpose the roots of the laurel are much used. Above the basket there is an arch or handle by which it is suspended. Again, earthenware vessels, to be suspended by wires, are offered for sale in a variety of shapes. Some of these are molded and painted in imitation of logs, and are known as "stick baskets" and "log baskets." Such baskets are often without provision for drainage. When this is the case, holes should be drilled at the lowest point in the bottom. A special form of basket is much used for orchids. It is made of square cedar slats in raft- or log-fashion. Fern-fiber and broken bits of brick, flower-pots or charcoal, are used for filling them. See also the article *Vases*.

476. Rustic basket (with *Convolvulus*).

ERNEST WALKER.

**BASSWOOD:** *Tilia*.

**BATĀTAS:** *Ipomœa*.

**BATEMĀNNIA**, (James Bateman, a distinguished collector and cultivator, and author of important orchid works). *Orchidaceæ*. Epiphytic; greenhouse.

Stems thickened into pseudobulbs, 1-3-lvd.: lvs. plicate-veined: racemes arising from base of pseudobulbs; sepals and petals similar in shape; lip articulated to the foot of the column, the lateral lobes inclosing the column, the middle lobe short, entire; pollinia 2.—A single species, native of Guiana, rarely seen in cult.

**Cölleyi**, Lindl. Pseudobulbs 2-3 in. long: lvs. up to 10 in. long: raceme pendulous, with 4 or more distant fls. about 3 in. diam.; sepals and petals vinous, purple, the lateral sepals green-margined; lip white, red-

dish stained at the base of middle lobe. B.R. 1714. B.M. 3818.

GEORGE V. NASH.

**BATODÉNDRON:** *Vaccinium*.

**BAUËRA** (H. Gottfr. and Franz Bauer, German professor and painter, respectively). *Saxifragaceæ*. Choice little evergreen shrubs grown in greenhouses.

Leaves 3-parted and opposite, looking like a whorl of 6: fls. white to purple, axillary and solitary, but sometimes aggregated at top of the st.; calyx 4-10-divided; petals as many as the calyx-divisions; stamens few to many, borne on a disk: fr. a 2-valved caps., the valves again splitting.—Three species in Austral. and Tasmania, one of which is in cult.

These small shrubs make handsome specimen plants for the cool greenhouse, and flower most of the year, especially during the winter and spring months. Baueras are easily propagated from cuttings of half-ripened wood in spring; cut into lengths of about 2 inches, insert in equal parts of finely sifted peat and sharp sand in 3-inch pots, pricking them round the rim of the pot, and cover with a bell-glass in a greenhouse with a temperature from 55° to 60°. Give them a thorough watering at the time of insertion, and they will frequently root without further watering. When the cuttings begin to show signs of growing, they should be potted singly in 2-inch pots in the same mixture as above, and should be kept in a tight case for a few days. After they have gripped the soil, they should be cut back to about an inch above the pot, which will encourage them to branch. Baueras should never be allowed to become pot-bound until the desired size of plant is reached. The plants at all times should be kept in good shape by cutting back the strong shoots. In summer, baueras do better when plunged in a bed of coal-ashes out-of-doors, and strict attention given to watering. A cool greenhouse with a night temperature of 40° to 45° will be ideal all winter.

Water occasionally with soft-coal soot mixed in water, a handful to an ordinary watering-pot; water with clean water three times and the soot-water once. (Geo. F. Stewart.)

**rubroides**, Andr. Erect or prostrate, usually 1-2 ft. in cult., but becoming 6 ft. or more: lfts. oblong or lanceolate, somewhat acute,  $\frac{1}{4}$ - $\frac{1}{2}$  in. long, serrate: fls. pink or white, slender-pedicelled, the very obtuse petals exceeding the spreading or reflexed acute-toothed calyx-divisions. Inhabits swampy places. B.M. 715. L.B.C. 14:1313 (as *B. rubæfolia*).—An old favorite, blooming in spring.

L. H. B.

**BAUHÍNIA** (after John and Caspar Bauhin, sixteenth century herbalists, the twin leaflets suggesting two brothers). *Leguminosæ*. MOUNTAIN EBONY. ORCHID TREE. Tropical trees and shrubs, sometimes climbing, planted in southern Florida and southern California to some extent for the flowers, odd foliage, and general attractive appearance; distinguished by the usually bifid or binate leaves; allied to *Cercis*.

Trees, shrubs, or vines, with showy fls. ranging from white to purple and yellow: lvs. broad, entire or 2-lobed, in some cases the lfts. being entirely free; petiole prolonged into a short but characteristic awn between the lfts.: fls. in simple or paniced terminal or axillary

racemes; petals 5, somewhat unequal, usually narrowed into a claw; stamens 10, but sometimes reduced even to 3 and perhaps bearing sterile filaments; ovary stalked, stigma in some species peltate and in others oblique; fr. a long flat pod, dehiscent or indehiscent.—About 150 species in tropics of both hemispheres. The number and fertility of the stamens are important characters in determining the subgenera. The purplish fls. of some species suggest those of some kinds of pelargonium. The bauhinias are not papilionaceous. Some of the arboreal species (as *B. variegata*) produce ebony wood. Others are gigantic climbers, sometimes mounting the highest trees.

Bauhinias are frequent in plantings in many parts of the tropics. They are planted to some extent in southern Florida and southern California. Numbers of species are likely to be introduced from time to time because of their gorgeous appearance in the tropics. In the experience of Old World gardeners, the most reliable species under glass are *B. variegata*, *B. corymbosa*, and *B. natalensis*. These can be planted outside in southern Florida in summer, and kept over winter as oleanders are. *B. variegata* and *B. purpurea* are two of the commonest and showiest small trees of India, and, although frequently introduced into northern greenhouses, have rarely succeeded permanently. *B. variegata* is much cultivated in India. The astringent bark is used in tanning and dyeing, and the leaves and flower-buds as a vegetable, the latter being pickled. Bauhinias thrive in a variety of soils on our southernmost borders. They delight in high well-drained land, but will grow on lower lands in southern Florida if it is fairly well drained or if set on slight mounds; all of them are very tender and easily affected by low temperatures, but are easily saved by banking. *B. purpurea* and *B. variegata* (*B. alba*) have withstood a temperature of 26° F. in Florida. No particular care in tillage or fertilizing is necessary, but better bloom is secured if some attention is given to these details. From seeds in Florida bauhinias grow readily and bloom freely in three or four years. Cuttings root with difficulty, but some kinds propagate readily from suckers. Bauhinias are little known as greenhouse subjects; but in the tropics they make showy and very attractive shrubs or small trees or profuse vines. (E. N. Reasoner.)

## INDEX.

<i>acuminata</i> , 4.	<i>Galpinii</i> , 3.	<i>purpurea</i> , 11.
<i>alba</i> , 12.	<i>grandiflora</i> , 5.	<i>tomentosa</i> , 9.
<i>candida</i> , 12.	<i>Kappleri</i> , 10.	<i>triandra</i> , 11.
<i>corymbosa</i> , 2.	<i>Krugii</i> , 12.	<i>variegata</i> , 12.
<i>forficata</i> , 8.	<i>natalensis</i> , 6.	<i>yunnanensis</i> , 1.
<i>furfuracea</i> , 8.	<i>picta</i> , 7.	

A. Plant climbing, or at least of climbing habit or tendencies.

1. *yunnanensis*, Franch. Vigorous, glabrous and glaucous throughout: lvs. coriaceous, bipartite; segms. obliquely elliptic, 3-4-nerved, rounded, 1½ in.: fls. in many-fld. pendulous racemes, rosy white striped with purple. Yunnan, China. B.M. 7814.

2. *corymbosa*, Roxbg. Woody climber, branching from the ground: branches grooved: tendrils opposite, revolute: lvs. 1½-2 in. long, outer edges slightly rounded, inner edges straight and parallel; lfts. nearly free from each other; nerves 2-4: fls. numerous, corymbose, 1 in. across, rosy, with fluted petals, and characteristic venation; stamens bright red, 3 very long, the rest abortive. China. B.M. 6621. G.C. II. 16:204.

3. *Galpinii*, N. E. Br. Half-climbing shrub, 5-10 ft.: lvs. 1-3 in. long, 2-lobed from one-fifth to one-half their length, 7-nerved; petiole about ¼ in. long: racemes 6-10-fld.; fls. borne continuously from spring to late autumn; petals 5, all alike, 1-1½ in. long; claw as long as the limb; limb orbicular, cuspidate, brick-red; fertile stamens 3: pod 3-5 in. long; seeds dark brown. S. and Trop. Afr. B.M. 7494.—Discovered 1891.

AA. Plant upright, a bush or tree.

B. Fls. white.

4. *acuminata*, Linn. Height 5-6 ft.: lfts. ovate, acuminate, parallel, 4-nerved, closing at night: fls. 2-3 in. across; fertile stamen long and nearly free, the other 9 short, connected, and sterile. India, Malaya, China. B.M. 7866. J.H. III. 44: 343.—One of the most satisfactory of all, either for open ground or greenhouse culture, as it will bloom the first summer, when but a few months old and but a foot or two high, and in succeeding summers blooms continuously from May to Sept.

5. *grandiflora*, Juss. Tree, to 20 ft.: lvs. oval or subcordate, tomentose beneath, not deeply divided, the lobes ovate-obtuse and 3-4-nerved, stipules spiny: fls. very large, pure white, opening at night, 1-3 on axillary peduncles; petals obovate, acute at apex, clawed. S. Amer. R.H. 1897, p. 393.

6. *natalensis*, Oliver. Small shrub: lvs. numerous; lfts. each 1 in. long, with a midrib and a few nerves, dark green; petioles ¼-½ in. long; lfts. entirely free: fls. single or in 2's, 1½ in. across, white, the midvein of the 3 upper petals reddish; petals erect or spreading, the 2 lower ones larger; stamens 10, 5 long and 5 short: pod 3 in. long. S. Afr. B.M. 6086.—Not advertised at present.

7. *picta*, DC. Unarmed: lvs. roundish elliptic, membranous, glabrous; lfts. semi-ovate, acutish, 5-nerved: fls. in solitary terminal racemes, white; calyx ferrugineous-tomentose; petals oblong. Colombia.

BB. Fls. colored (cream-color, yellow, or shades of red or purple).

8. *forficata*, Link (*B. furfuracea*, Hort.). Thorny shrub: lvs. cordate at base, glabrous, cleft to middle: fls. cream-color in summer, rather bell-shaped, the petals narrow. Brazil. B.M. 3741. Gt. 10:333.

9. *tomentosa*, Linn. ST. THOMAS TREE. Erect shrub or small tree, branches downy: lvs. broader than long, 1-2 in. long, coriaceous, the lobes obtuse, 7-nerved: fls. mostly in axillary pairs (sometimes 1 or 3) on pedicels bearing a pair of bractlets, yellow with red blotch on the upper petal, the petals 2 in. or less long, obovate, much exceeding calyx (which is entire): pod stalked, 4-5 in. long. India. B.M. 5560.

10. *Kappleri*, Sagot (*B. Krugii*, Urban). Fig. 477. Strong tree, to 50 ft.: lvs. 2½ in. or less long, long-petioled, longer than broad, truncate or somewhat cordate at base, divided about one-third of the length into obtuse lobes that are about 5-nerved: fls. in short racemes opposite the lvs., whitish rose with darker and purple markings, the petals spatulate and clawed; lower stamens fertile: pod 6-10 in., narrow and curved. Probably French Guiana; cult. and partly spontaneous in W. Indies.—Attractive.

11. *purpurea*, Linn. (*B. triandra*, Roxbg.). Small to middle-sized tree: lvs. coriaceous, glabrous, somewhat cordate, cleft one-third to one-half their depth, 9-11-nerved; lobes obtuse or somewhat acute: fls. in few-fld. axillary and terminal corymbs, fragrant; petals red, one streaked with white on the claw, oblanceolate, acute; fertile stamens 3-4, very long, the rest sterile or abortive: pod 1 ft. long. India, Burma, China.—One of the finest flowering small trees in S. Fla. Fls. are borne in the greatest profusion, 3-5 in. across, varying in color from almost white to a shade of rich purple, and marked and shaded with many tones. The plant is

477. *Bauhinia Kappleri*. (× ½)

robust and hardy, growing to a height of 15 ft. in less than 2 years, and blooms all winter and spring. What is known as *B. triandra* to Fla. cultivators is described as a very tender species but succeeding admirably there; growth like that of *B. purpurea* but with longer willowy branches that bear at the tips great clusters of pink fls. in late autumn or early winter, delicately scented.

12. *variegata*, Linn. Much like *B. purpurea* in habit: tree, 6–20 ft.: lvs. 3–4 in. across, somewhat broader than long, divided one-fourth to one-third the depth, 9–11-nerved, lobes rounded; petiole 1–2 in. long: fls. about 7, in a short raceme or corymb, 4 in. across; calyx spathe-like; petals 5, clawed, obovate-oblong, veined, rose-colored and variegated with red and yellow, the lowest one larger, broader above the middle, strongly marked with crimson; pod 1–2 ft. long. India. B.M. 6818.—The coloring of the fls. varies. Var. *cándida*, Roxbg. (*B. álba*, Buch-Ham.). Height 12 ft.: fls. white, beautifully veined with green: fls. Feb.–May. B.M. 7312.

Numbers of baubins may be expected to appear in plantings along the southern borders. The following names have already occurred: *B. andicans*, Benth. Closely related to *B. forficata*. Spiny: branchlets and racemes whitish tomentose: lvs. pubescent below, 9-nerved: petals nearly 3 in. long. Uruguay, Argentina.—*B. Hobkerv*, F. Muell. Large tree: fls. distinct, broad, very obtuse, 5–7-nerved: fls. white, edged with crimson, in few-fl. terminal racemes; petals clawed, the blade about 1½ in. long. Austral.—*B. Richardsonii*, said to be from Mauritius; unidentified.

L. H. B.†

BAY TREE: *Laurus*.

**BEAN.** A name applied to various plants of the *Leguminosæ*. The word is commonly used for herbaceous plants of the *Phaseolus* tribe, but it is sometimes employed for seeds of leguminous trees and shrubs. The species of true beans (*Phaseolus* and closely allied genera) are yet imperfectly understood. The bean differs from the pea, among other things, in being epigeal in germination (cotyledons appearing above ground). Some of the plants to which the name is applied are really peas.

The beans chiefly known to horticulture are of five types: (1) The Broad bean (*Vicia Faba*), or the bean of history, an erect-growing plant, producing very large and usually flat, orbicular or angular seeds. Probably native to southwest Asia (Figs. 478, 479 a). See *Vicia*. These types of beans are extensively grown in Europe, mostly for feeding animals. They are either grown to full maturity and a meal made from the bean, or the plant is cut when nearly full grown and used as forage

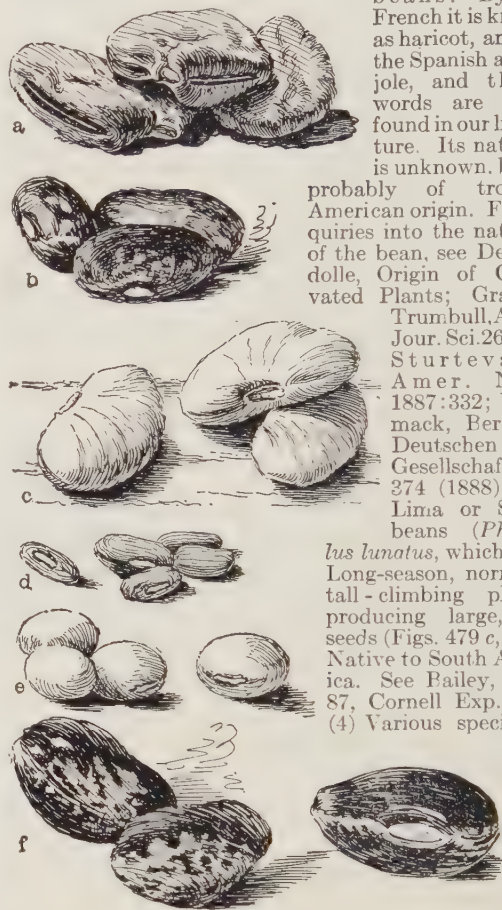

or made into silage. The Broad bean needs a cool climate and long season. In the United States, the summers are too hot and dry for its successful cultivation on a large scale, and the plant is practically unknown here. In Canada, the plant has been used with corn to make silage; and this combination has been called the "Robertson mixture." (2) Kidney bean (*Phaseolus vul-*

*garis*; Figs. 479b, 480). This is the plant which is everywhere known as bean in North America, comprising all the common field, garden, snap and string

beans. By the French it is known as haricot, and by the Spanish as frijole, and these words are often found in our literature. Its nativity is unknown, but is

probably of tropical American origin. For inquiries into the nativity of the bean, see DeCandolle, *Origin of Cultivated Plants*; Gray & Trumbull, *Amer. Jour. Sci.* 26:130; Sturtevant, *Amer. Nat.* 1887:332; Wittmack, *Ber. der Deutschen Pot. Gesellschaft*, 6: 374 (1888). (3) Lima or Sugar beans (*Phaseolus lunatus*, which see).

Long-season, normally tall-climbing plants, producing large, flat seeds (Figs. 479 c, 481). Native to South America. See Bailey, *Full.* 87, Cornell Exp. Sta. (4) Various species of

479. Types of beans. (Natural size.)

a. *Vicia Faba*. b. *Phaseolus vulgaris*. c. *Phaseolus lunatus*. d. *Dolichos sesquipedalis* (properly a *Vigna*). e. *Glycine hispida*. f. *Phaseolus multiflorus*.

*Dolichos* (as *D. sesquipedalis* of gardens), or closely related things. Vines which produce very long, slender pods and small, narrow beans (Figs. 479 d, 482). Native to tropical America. (5) Soy, or Soja, bean (*Glycine hispida*). A bushy, erect, hairy plant producing small pods in clusters, and pea-like seeds (Figs. 479 e, 483). In this country used mostly for forage. Native to China and Japan, where it is much grown.

Aside from these types, there are others of less economic importance. The Scarlet Runner type is a perennial *phaseolus* (*P. multiflorus*), grown in this country mostly for ornament (Figs. 479 f, 484). The Tepary bean, now gaining prominence in the Southwest, is a form of *Phaseolus acutifolius*, a native species. Various other species of *Phaseolus* are also cultivated in various parts of the world under the name of beans. *P. radiatus* is prized in Japan, and has been introduced into the United States as Adzuki Bean (see Georgeson, *Bull.* 32. Kan. Exp. Sta.). *Vigna sinensis*, known in North America as cowpea (which see), is sometimes called a bean. The Velvet bean of the South is a *Mucuna* (which see), recently, however, referred to *Stizolobium*. The Jack bean is a *Canavalia* (Fig. 485). Recent American studies on varieties and types of beans are Irish, *Rep. Mo. Bot. Gard.* 1901, 81–165;

478. Broad bean—*Vicia Faba*. (X ¼)

Jarvis, American Varieties of Beans, Cornell Bull. 260 (1908); Freeman, Ariz. Bull. 68 (1912).

The sea beans of the Florida coast are seeds of various tropical leguminous plants, and are transported by ocean currents (see Coe, in G.F. 7:503).

For botanical treatment, 'see *Dolichos*, *Glycine*, *Phaseolus*, *Vicia*, *Vigna*.

L. H. B.

### Culture of the bean.

For the purposes of the practical gardener, the various types and numerous varieties of the bean may be classified in two groups, in two different ways, namely,

480. Common or Kidney bean.—  
*Phaseolus vulgaris*.

either as "field beans" and "garden beans," or as "bush beans" and "pole beans." Field beans are grown on a large commercial scale for the dry-shelled seeds, either as a farm crop in regular rotation, as corn and potatoes are grown, or at times as a subsidiary or chance crop, or side line, in young orchards, and so on, but are not usually found in the home- or market-garden, where highly manured soil would tend to stimulate

growth of foliage at the expense of seed-production. Field beans belong mostly or entirely in the class of bush beans. The garden beans are more commonly grown for their succulent pods and immature seeds, and include both bush and pole or "running" sorts. The latter come almost exclusively under the head of "garden" beans.

The great economic value of the bean is generally recognized, not alone in respect to its high place as a farm and garden crop, but also as the most suitable material, next to animal products, in compounding a balanced ration for man, and to some extent for beast, and as a substitute for dear meats.

Beans are easily forced under glass, in a temperature suitable for tomatoes. They may be grown either in pots or beds. The bush varieties, as *Sion House*, are preferred. Keep them growing, and look out for red spider.

### Field beans.

Ordinary field beans like a fairly good warm farm soil, such as will suit corn or potatoes. They do not draw very heavily on the fertility of the land. Belonging to the legumes, they are able to make use to a large extent of atmospheric nitrogen, and if given a good start will not only look out for their own needs in that respect, but may leave the land better supplied with nitrogen than it was found at planting-time. They will not thrive on wet or badly drained land; otherwise good strong loams, or soils resting on limestone, are considered most desirable, with sandy loams and gravelly loams next in order. They should have a fair but not excessive amount of humus. A few loads of fine old stable manure spread evenly on the surface after plowing, if possible supplemented with fifty or a hundred pounds of muriate of potash and a few hundred pounds of dissolved rock (acid phosphate) or other phosphatic manure may be expected to give good re-

turns. Or, in the absence of these chemicals, 200 pounds or so of a commercial fertilizer such as is usually applied for grain crops, and which analyzes about 2 or 3 per cent of nitrogen, 8 of phosphoric acid and 3 or 4 of potash, may be applied broadcast after plowing. Although the planting should not be done until after the soil has become warm, in the northern states not before June, the customary planting-time in the great bean-producing sections extends from June 1 to June 25; it is, nevertheless, of great importance to plow the land early and keep it worked with disk or other harrows until planting-time; this for the purpose of preserving moisture and getting ahead of the weeds. Important also is the use of good hand-picked seed beans, not over one year old, and free from weevils and disease infection. The rows are to be made 28 to 36 inches apart, and for small areas, planting by hand or with a corn-planter will do. For planting on a larger scale, a regular bean-planter or a grain-drill with part of the tubes stopped up so as to bring the rows the correct distance apart should be used. If fertilizer is to be applied with the drill at the same time, it may be allowed to run from the hoe or tube on each side of each tube that discharges the seed beans.

Among the varieties generally grown in field culture are the *Pea or Navy*, the *Medium*, *Red and White Kidney*. The *Pea bean* is small but early and prolific, and considered to be about as profitable as any other under ordinary circumstances. It is particularly recommended for the small or home grower.

The harvesting comes when the pods have ripened and the leaves have dropped off, and is to be done with a bean-puller or harvester, taking two rows at a time, or in a small way by hand-pulling. The vines are put in small heaps, allowed to cure, and promptly stored out of the way of moisture, afterwards threshed with a bean thresher, or in a small way with the flail, cleaned, sorted by hand (in a large commercial way with the help of a bean-sorting device), and marketed.

### Garden beans.

The warm and fertile soil of the average home- or market-garden suits the requirements of the "garden" beans, as they are mostly grown for their tender and succulent pods and not for their seeds, or, as in the case of the lima and several others, for their seeds in an immature or half-developed state. The pods of all these garden beans should be picked promptly and clean in order to prolong the bearing period as much as possible. If the beans are allowed to ripen on the vines, the latter will soon give out. Only when these garden beans are grown for seed purposes is early and even ripening desirable, and in that case the pods, perhaps with the exception of the first setting if light, must all be left on. A good string bean has a thick, meaty pod which snaps off clean when broken, leaving no string along the back.

481. Large White Lima bean  
( $\times \frac{1}{2}$ )

Many varieties which answer this description are offered in the various seedsmen's lists, both green-podded and yellow-podded. *Early Valentine*, with its many strains (*Red*, *Black*, *Earliest Improved*, and so on), is still in favor with growers for a green-podded variety. A newer good one is *Stringless Green-Pod*. Quite numerous are the yellow-podded sorts. Among them are *Black Wax*,

Golden Wax, Davis Kidney Wax, Wardwell Wax, Hodson, and others.

#### *Pole beans.*

Pole or running varieties of beans require especially fertile soil; and for that kind of table beans, the lima of all forms, too much can hardly be done in the way of enriching the ground. Warm soil is one of the first essentials of success in growing pole beans. When poles are to be used for support, they should be set not less than 4 feet apart each way, before the beans are planted. Four or five beans are to be placed around each pole, 1 to 1½ inches deep. While it is a safe rule to put the seed eye downward, it is not a necessary condition of prompt and uniform germination. In case of absence or scarcity of poles, a serviceable, cheap and ornamental trellis may be constructed by setting posts firmly at proper distances along the row, connecting them with two wires, one a few inches and the other 5 or 6 feet from the ground, and finally winding cheap twine zig-zag fashion around the two wires. Cultivate and hoe frequently. A top-dressing of good fertilizer, or of old poultry- or sheep-manure, hoed in around the plants, may be of great help in keeping up the productiveness of the plants to the end of the season. To have a continuous supply during the entire season, the pods, when large enough, must be gathered frequently and clean. Among the varieties used both for string and shell beans, are the Green-podded Creaseback,

482. Yard-long Bean. A species of *Vigna*.

several wax varieties, Golden Cluster, and the popular Horticultural or Speckled Cranberry bean, besides any number of others. A very fine bean is the Dutch Runner (Fig. 484), which approaches the lima in quality and resembles it in habit of growth. The seed is of the largest size and clear white in color. Highly ornamental is the closely related Scarlet Runner, with its abundance of showy scarlet blossoms. This latter bean is grown in Europe for eating, but is rarely used for that purpose here.

#### *Lima beans.*

Of all pole beans, the limas have undoubtedly the greatest economic value. They enjoy a deserved popularity, and are usually grown with profit by the market-gardener. The varieties might be classed in three types,—that of the Large Lima, the Dreer Lima, and the Small Lima or Sieva. Each of them has a number of sub-varieties or strains, and appears in both pole and bush form. The old Large Lima (Fig. 481) is a very large, flat bean, and yet largely grown for main crop. To the same type belong Extra-Early Jersey, King-of-the-Garden, and others. The pods of these are very large, and the beans in them somewhat flattened.

There are dwarf forms of both sieva and the regular lima. The Burpee Bush Lima is a form of the large lima type. The Dreer Lima of both forms is appreciated especially for its high quality. The seeds are more roundish and crowded close together in the pods, the latter being much smaller than those of the Large Lima. The seeds of these two types are light-colored, with a

greenish tinge, but the Large Lima is also represented by red and speckled (red-and-white) sports. The Small Lima or Sieva, with its dwarf form, Henderson Bush Lima, seems to be hardier and earlier than the two larger types, but pod and bean are quite small. The color of this bean is nearly clear white, but there is also a speckled sub-variety of it. Wherever there is a place for the Sieva, its bush form will be appreciated. The bush forms of the two larger types, however, are not uniformly productive enough to take the place of the pole forms entirely. The latter will often be preferable when a season of continuous bearing is desired.

Lima beans require a long season, and therefore are not much grown along the northern borders and in Canada. They must be given warm and "quick" soil and kept constantly growing.

#### *Other beans.*

Three other members of the bean tribe might be mentioned in this connection; namely, the Black bean or cowpea of the South, the Japanese Soy bean, and the English or Broad bean. The cowpea takes, in some measure, the same place in the southern states that red clover takes at the North, being used both as stock food and as a green-manure crop. There are many varieties of it, early and late, some of strictly bush habit and some producing long runners. See *Cowpea*. Of greater value for the same purposes, north of New Jersey, seems to be the Japanese Soy bean, which is early enough to come to maturity almost anywhere in the United States. Its foliage is rather thin or open, however, which impairs its value for green-manuring. The dry bean constitutes one of the richest vegetable foods known, and its flavor seems unobjectionable to all kinds of stock. Sow one bushel to the acre. Similar to this in value is the English Broad bean, several varieties of which, as the Broad Windsor, the Horse bean, and others, are grown and are popular in England and in some parts of the European continent. In most parts of the United States they are scarcely known, and in none generally cultivated. Only a few of our seedsmen list them in their otherwise complete catalogues. Yet they are a decidedly interesting group of plants, and worthy of greater attention in the cooler parts of the country. Being about as hardy as peas, they may be planted much earlier than would be safe for ordinary beans. The Windsor is used in England in much the same way as lima beans are used in America; but the latter are so much better that in the United States there is no need of planting the former as a table vegetable. The varieties with smallish seeds are sometimes grown and used in parts of Europe for feeding pigeons and chickens, and under certain conditions might have some value here for the same purpose on account of the high protein content.

#### *Insects and diseases.*

The foliage of the various beans is rarely attacked by insects. A somewhat serious pest, however, which attacks the seeds both in the pod and dry, after being shelled, is the bean-weevil, a smaller brother of the pea-weevil, and having nearly the same general habits of development. If only beans free from live weevils are used for seed in a given locality, the product will be free from them also. For that reason, all beans to be used for seed, or for food, if suspected of being weevil-infested, should be subjected to the carbon-bisulfid treatment in the fall. It is simple, but care should be taken to keep the highly inflammable drug away from an open fire or light. Place the beans in a tight receptacle. Pour a quantity (half pint to barrel) of the bisulfid into a saucer or other flat dish, which place on top of the beans, and cover the receptacle tightly, leaving it thus for twenty-four hours or more.

Difficult to control is the bean blight, a disease which frequently affects field, garden and lima beans. Seed

XIII. Bean.—The Bush Lima.

from an affected field should not be used, nor should beans be planted again on a field for several years after having been affected. For bean anthracnose, also called bean rust (erroneously) and pod-spot, which is easily recognized by the dark or brownish spots on the pods and occurs both on field and garden beans, there is one sure preventive. Plant clean seed and grow a practically clean crop. It is advisable for the grower to select his own seed beans, carefully rejecting every pod that shows the least sign of the disease. The true bean rust is not so often met with, therefore not so serious.

T. GREINER.

#### Lima beans in California.

Lima beans are grown in California very extensively as a field crop, supplying the markets of the country with the bulk of the dry shelled product. The figures for the lima bean crop of 1910 in California are as follows:

	Sacks
Ventura County.....	800,000
Orange County.....	150,000
Santa Barbara County.....	75,000
Los Angeles County.....	75,000
San Diego County.....	60,000
Total.....	1,160,000

The above represents a total of about 82,850 acres devoted to this crop.

Lima beans delight in warm, summer weather, but if the relative humidity is low, they suffer in consequence. Along the California coast, which is the heaviest producing section, the fogs are remarkably constant in the night and early morning, and when for a week or ten days these fogs are lacking, the bean crop suffers markedly. The small pods that are just forming dry up and fall off without making seed. The heavy fogs which roll in may add a little moisture to the surface soil for a time, but not enough to reach the roots and aid the plants directly. The great benefit of the fog is in lessening evaporation and tempering the atmosphere, less water passing from the plant into moist atmosphere than would pass into dry atmosphere.

The profitable production of lima beans is limited to some extent by soil, though not so much as by climate. They are grown on soil ranging all the way from sandy to adobe. The lima bean plant does not grow well on an acid soil; neither does it thrive on an alkali soil. California soils, being mostly arid or semi-arid, are not

badly leached, and therefore lime is usually abundant, insuring freedom from acidity. But the same aridity and consequent lack of leaching is responsible for the accumulation in some lands of considerable amounts of alkali salts, enough to limit the area and the production in the counties where the bulk of the limas is grown. The amount of alkali which this bean can endure and still produce paying crops has not been definitely determined, but it is not high. However, experience has shown that the lima

will bear more alkali than the Blackeye, Lady Washington, or other beans of the common kidney type.

The difference in time of maturity is very great between sandy and clayey soils, and still greater between dry and moist soils. A difference of a week may be observed in the same field, due to physical variations in the soil, and much more than this difference in time has been frequently observed within the distance of a few miles. It seems that the water-supply of the soil more than the texture is responsible for this difference in time of ripening, as irrigation on light soils causes the same lateness in maturity. Thus, a tendency is found toward the perennial habit which the plant maintains under the humid conditions of the tropics.

Soils with much nitrogen tend to produce late maturity; hence the limas ripen later on land which has been recently manured. On the other hand, the mineral elements tend toward early maturity. Limas require a richer soil than do the white kidney beans; the pole varieties require a richer soil than the bush varieties.

The standard preparation of land for a bean crop is practised. Growers have learned by experience that good preparation pays; in fact, very much more cultivation is given the soil before seeding than after.

Planting is from May 1 to May 25, at the rate of forty-five to sixty-five pounds per acre, according to the moisture condition and fertility of the soil. The beans are planted in rows 30 to 36 inches apart, 8 to 12 inches apart in the row, a single seed being dropped in a place. On the heavier and more moist soils, where the growth of vines is rank, the wider distances are given between rows. Two inches in the moist soil is considered the best depth of planting.

The beans are tilled while young, one, two or three times, the average number of cultivations being two or a little more. The fields are ordinarily kept free from weeds from the time of working in the winter till the vines cover the ground. Cultivation must cease when the vines get large, as, not being provided with supports, they spread across the row and would be badly injured by the passage of the cultivator. After the vines have made such a growth as practically to cover the ground, the mulch is not so much needed to prevent evaporation.

#### Irrigation in California.

As there is normally no rain on the bean crop in California from planting till harvest, the ground, of course, becomes very dry. Hence irrigation has been found profitable, the production in many fields being doubled by the use of water. The most common method of irrigation is by the row system. Furrows are made between all the rows with an implement carrying four broad shovels, furrowing between four rows at a time. Water is run in these furrows for the desired time, after which the land is leveled by a shallow cultivation. This prevents excessive evaporation which would take place if the furrows were allowed to bake in the sun. Usually only one irrigation is given, and that about July 1st, just before cultivation ceases. Two and

484. *Phaseolus multiflorus*.  
( $\times \frac{1}{2}$ )

483. Soy bean.—*Glycine hispida*. ( $\times \frac{1}{4}$ )

one half to 3 acre-inches per acre are applied at this time.

#### *Harvesting, and caring for the product.*

In the sections of light and unirrigated land, the beans ripen from August 20 to September 10. In the irrigated parts and on heavier land, they ripen from September 10 to September 25 or October 1. These dates indicate the time the beans are harvested. Before the earliest date for each section there will be some dry pods in all the fields and at the latest date of harvest there are always green pods.

The beans are harvested by a seed-cutter with two runners 12 to 15 inches high. On the inner side of each a knife is set diagonally backward and toward the middle of the sled. A few inches above each knife is a bar of iron or wood set in a similar position. The sled-runners are such a distance apart that two rows of beans will pass between them. Hence each knife is drawn along the line of the row cutting the plants just below the surface of the ground. The diagonal position of the knife causes it to cut the plants clean without pulling up by the roots, and together with the diagonal bar above, pushes both rows to the middle, leaving them together in a windrow. These cutters are often mounted on wheels to bear the main weight of the sled and driver, the runner cutting into the ground just enough to hold it firmly to the row. Levers are provided to raise and lower the frame of the sled. A man with two or three horses, usually three, cuts from 8 to 12½ acres a day.

The vines, after lying in windrows for a few hours, as left by the cutter, are piled by hand with pitchforks. Three windrows are commonly placed together in one row of piles. Piles are 4 or 5 feet in diameter on the ground and 3 feet high. They remain in these piles till very dry, which is a length of time varying with the weather and the maturity of the beans, but usually from two to three weeks. A man is expected to pile about 5 acres a day, but frequently does not pile more than 2 or 3 acres. It requires from two to three men to handle the beans cut with one sled.

Threshing is done by itinerant machines, using for power either steam or gasoline engines. The machines thresh from 1,000 to 2,500 sacks per day, 1,500 being a fair day's work. In a few instances about 3,000 sacks have been threshed in a day. The charge is usually 25 cents a hundred pounds, equal to 20 cents a sack. The beans are stored in large warehouses until marketed, and are generally recleaned by a mechanical recleaner which is very satisfactory.

#### *Yield and value of crop.*

The average yield is about fourteen sacks, eighty pounds per sack, or about 1,120 pounds per acre. Some fields produce nearly three times this amount, but in

the best section an average of twenty-five sacks or 2,000 pounds per acre is considered to be satisfactory.

Another factor which is of importance, and which has only recently come to be appreciated, is the value of the bean straw as rough feed. It is generally regarded that the straw is worth about \$1 per ton in the field, loose.

GEORGE W. SHAW.

#### **Tepary beans.**

The tepary is a small white bean native to the southwestern region of the United States (*Phaseolus acutifolius* var. *latifolius*), long grown by the Indians and now receiving attention from general cultivators. The first full account is in Bulletin 68, Arizona Experiment Station (1912).

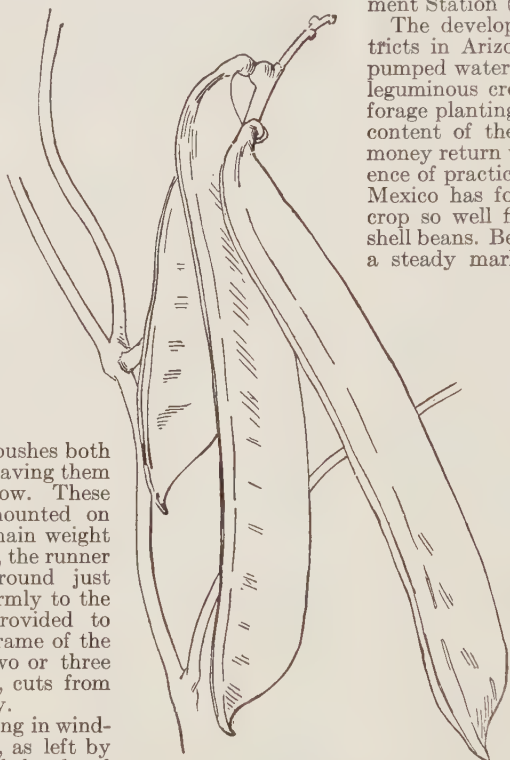

The development of artesian and dry-farming districts in Arizona, together with the increased use of pumped water for irrigation, have created a need for a leguminous crop which, used in rotation with grain or forage planting, will maintain the nitrogen and humous content of the soil and at the same time provide a money return which is sure and profitable. The experience of practical farmers throughout Arizona and New Mexico has for years demonstrated the fact that no crop so well fills this demand as the growing of dry shell beans. Being a countrywide food staple, they have a steady market which is little influenced by local

conditions other than transportation charges. As corn in Illinois, cotton in Texas or wheat in Kansas represent to their producers products of staple value, so may the dry-farmers of the Southwest, and those irrigating with artesian and pumped waters, look to the bean as a money-crop which at all times may be surely and readily turned into cash.

Varieties of beans originated in the humid sections of the East are of but little value when grown in Arizona. They do not withstand satisfactorily the extreme aridity and heat of the air during the summer months. Out of a large number of varieties tested at Yuma, only those of southwestern origin were at all successful.

Among these southwestern varieties of beans, first tested at Yuma in 1909, certain ones were noted which gave yields far in excess of all others, including even the much-prized pink bean, or frijole. Subsequent investigations developed the fact that this group of

varieties (known as teparies) was distinct from either the common kidney or snap bean. They were found to constitute a new species, hitherto unrecognized as a cultivated plant in botanical or horticultural literature. It has been described by the writer as a new variety of *Phaseolus acutifolius*. In its wild state, *Phaseolus acutifolius* is peculiar to the southwestern desert region. It may be found on the mountain-sides and in narrow valleys from the Pecos river westward across New Mexico and Arizona and southward into the adjoining states of Mexico. Domesticated from the neighboring cañons and cultivated in small patches, attended at best by a crude husbandry and dependent upon the precarious summer rains and uncertain floods from the mountain washes for irrigation, the tepary has lost none of its native hardiness. It has been cultivated by the Papago and Pima Indians from prehistoric times and in all probability formed one of the principal food-crops of that ancient and unknown agricultural race, the ruins of whose cities and irrigating canals are now the only witnesses of their former presence and prosperity.

485. The Chickasaw Lima, or Jack bean.—*Canavalia ensiformis*. ( $\times \frac{1}{2}$ )

While growing, the tepary may easily be distinguished from the common garden bean by its more slender vines and smaller leaves. The leaves are also thinner, smoother, narrower and more pointed at the apex than those of the bean. The pods are smaller than those of the bean, averaging about 3 inches long and  $\frac{3}{8}$  inch wide. Being somewhat flattened and having thin, rather tough walls, the pods might resemble rather closely a small variety of the lima. Teparies, however, differ markedly from either the bean or the lima in the length of the stems bearing the first pair of aerial leaves. For teparies these measure only about  $\frac{1}{8}$  inch, whereas for beans and limas they will average an inch or more. The seeds of the tepary are smaller than those of the other sorts mentioned and there are a number of minor differences which suffice to give them a distinctive appearance at least to those who are familiar with the group. The seeds of the white variety are very similar to those of the navy bean, with which they would in all probability be classed on the general market. A convenient test for shelled tepary beans is to immerse them in water. They will wrinkle in five to ten minutes; while other cultivated species commonly require forty-five minutes to one hour.

#### *The tepary as a food.*

There is considerable difference of opinion as to the relative palatability of beans and teparies. Among the Indians and Mexicans, the commercial pink bean is preferred to the tepary, as they say it has a better flavor. These people, however, make the same difference between the pink bean and the white navy which is shipped in from the East. Teparies should be soaked twelve hours before cooking, during which time they swell to at least twice their original volume and more than double in weight. In this respect they markedly surpass other beans. Well-cooked teparies are light and mealy and have a rich bean-like aroma. Boiled and baked with bacon or mashed and added to soups, they form most acceptable dishes. To such as are fond of the

486. Typical Snap, or String beans. (X  $\frac{1}{2}$ )

onion, a small amount of this vegetable finely chopped and stirred in during boiling makes a pleasing addition.

#### *Yields and culture.*

The superiority of the tepary over other beans for planting in the Southwest is exhibited in its greater productivity when grown under similar conditions. This statement is not only true in irrigated sections, but even more marked in regions devoted to dry-farming. In nine experiments in Arizona covering almost every condition of soil, culture and water-supply, and extending over three years, the average yield of the teparies has been slightly more than four times the average for varieties of the kidney bean. These greater yields are due to the ability of the tepary to germinate quickly in the presence of a low moisture-content of the soil, with the resulting better stands on dry lands. The tepary is also able to withstand protracted seasons of drought without permanent injury, returning to full vigor immediately when the rains come. Other beans do not possess this ability to a marked degree. The tepary is also inured to the greatest extremes of summer temperatures and will bloom and set seed any month from May to November. On the other hand, when the blooming period of common beans happens to

fall within a season of extreme heat, the buds will for the most part drop without setting pods. For these reasons the tepary is a more sure and dependable crop, often giving fair returns when beans are a total failure. With an ample supply of water, good soil and other conditions favorable, teparies should yield 700 to 1,200 pounds per acre. However, 1,500 pounds per acre have been reported from the Colorado Valley near Yuma. Under dry-farm conditions, yields of 450 to 700 pounds have been reported. On irrigated lands, teparies may be planted in southern Arizona any time from the early spring when danger of frost is past until August 10. The best crops however, are secured by early planting, March 20 to April 1, or by midsummer planting, July 12 to 25. In dry-farming, they are planted any time from the 10th to the 15th or 20th of July.

487. Bedding.—*Arundinaria Veitchii*.

GEO. F. FREEMAN.

**BEARBERRY:** *Arctostaphylos*.

**BEAR'S BREECH:** *Acanthus*.

**BEAUCÁRNEA:** *Nolina*.

**BEAUFÒRTIA** (Duchess of Beaufort, patron of botany). *Myrtaceæ*. Greenhouse red-flowered shrubs, blooming in spring.

Stiff, more or less heath-like shrubs: lvs. commonly opposite, small and rigid, often only 1-nerved: fls. in heads or short spikes, sessile; calyx 5-lobed; petals 5, spreading; stamens many, longer than the petals, in bundles opposite each of the petals; ovary 3-celled: fr. a loculicidal caps. borne in the hardened calyx-tube.—Twelve or 13 species in W. Austral. Requires the treatment of coolhouse Australian things, with peaty soil. Prop. by maturing shoots under glass.

**purpùrea**, Lindl. Small free-flowering shrub, with virgate branches: lvs. ovate-lanceolate or narrower, becoming linear on the small branches: fls. small, purplish red, the petals shorter than the erect subulate calyx-lobes.

L. H. B.

**BEAUMÓNTIA** (after Mrs. Beaumont, of Bretton Hall, Yorkshire, England). *Apocynaceæ*. Hothouse white-flowered twiner.

Corolla funnellform, short-tubed, without scales in the throat, with 5 broad lobes; stamens 5, included, attached to corolla; disk 5-lobed or of 5 scales. The genus is more nearly allied to the familiar greenhouse shrub *Trachelospermum jasminoides* than to the splendid tropical climbers in *Allamanda* and *Dipladenia*.—Four or 5 Indian or Javanese trees or tall climbers, with very large, white, fragrant, bell-shaped fls. in terminal cymes.

*B. grandiflora* has been neglected of late, presumably because it needs so much room. It should be planted out in strong, fibrous, loamy soil of a warm-house, as it rarely succeeds in pots. It is best trained to the roof, as full light is necessary for flowering, if not for growth. The shoots may be thinned if the large leaves cast too much shade on the plants beneath. The wood should be well ripened to produce an abundance of winter bloom. The flowers are produced on the

488. Bedding.—*Bambusa palmata*.

growth of the previous season. After flowering, the plant should be severely pruned to produce lateral shoots for the next season's bloom. In its native country, this vine climbs over very tall trees.

shrub with white, fragrant, shallow bell-shaped fls. Cochin China. G.C. III. 49:306.—*B. Jerdoniána*, Wight. Similar to the above but with smaller parts, and with foliicles 10 in. long. Cult. only in rare collections. Wight Ic., pl. 1314.

*grandiflora*, Wall. A tall-growing, woody vine: lvs. obovate, cuspidate, wavy margined: sepals 5, large, ovate, wavy, pink-tipped; corolla-tube veined with green, the limb 5-cleft. B. M. 3213. Gn. 45, p. 138; 49, p. 314. J.H. III. 28:243. Var. *supérba*, having larger whiter fls. than the type, is known.

*B. fragrans*, Pierre. Evergreen. N. TAYLOR.†

**BEDDING, or BEDDING-OUT.** The temporary use out-of-doors of plants that are massed for showy and striking effects. There are four main types: spring, summer, subtropical and carpet-bedding.

#### Spring bedding.

The most temporary of all forms of bedding is that designed only for spring effects. It is usually followed by summer bedding in the same area. It is the only kind that largely employs hardy plants, as crocuses, narcissi, daffodils, tulips, hyacinths, and other Dutch bulbs. All four types of bedding are commonly seen in public parks, but spring bedding is the most appropriate for amateur and home use, as the bulbs flower at a dreary time of the year, when their brave colors are most cheering, and also because they are much more familiar than the subtropical and foliage plants of summer. Moreover, hardy bulbs are more easily cultivated than any other class of plants, and they are cheap. The main principle is to plant them early enough to

490. French pattern.

1. *Calendula officinalis*, "Sulphur Queen." 2. *Ageratum nanum*, "Blue Perfection." 3. White geranium. 4. Scarlet geranium. 5. Pink geranium. Palm at center for accent. Whole design outlined with green *alternanthera*.

ding is the naturalizing of bulbs in the lawn. Crocuses and squills are particularly charming when they appear singly, or in twos or threes, at unexpected places in the lawn. Daffodils are frequently naturalized in large masses in spots where the grass is not mowed.

Pansies are the only other plants that are used extensively for spring bedding. English double daisies and catchflies are largely used for edgings. Pansies are set out between April 1 and 15. In large operations, pansy seed is sown in August of the preceding year, and the young plants are transplanted once and wintered in a coldframe. After flowering, the plants are thrown away. The other method is to sow the seed in a greenhouse in January. The August-sown pansies give larger and earlier blooms, but the January-sown pansies will last longer, and in partially shaded places will give scattering bloom all summer, especially if protected from drought.

#### Summer bedding.

Bedding for summer effects often follows spring bedding in the same space of ground, and employs chiefly geraniums, coleus, begonias, ageratum, salvia, vinca, alyssum, petunia, verbenas, heliotrope, grasses, cacti, and aquatic plants, the culture and varieties of which may be sought elsewhere in this work. As to tenderness, these fall into two groups, the first of which may be set out about May 15 in New York, and the second about June 1. Geraniums are the most important of the first group, and coleus is an example of the tenderest material, which is set out simultaneously with subtropical plants when all danger of frost is past.

As to fondness for sunlight, there are again two groups, but the only bedding plants of importance that

491. French border pattern.

prefer shade are tuberous begonias and fuchsias. The popularity lately achieved by tuberous begonias in Europe will probably never be duplicated in America. The secret of their culture is shade, shelter, and moisture at the roots. Therefore, a clay bottom is desirable for a bed of tuberous begonias, as being more retentive of moisture than a sandy or porous soil. They enjoy cool air and as much indirect light as possible, but not the direct rays of the sun. The north side of a building is better for them than a station under trees, as the trees usually give too dense a shade, and their roots interfere. On the other hand, coleus is more highly colored in full sunlight than in shade.

The only fibrous-rooted begonias largely used for bedding are varieties of the semperflorens type, of which *Vernon* and *Erfordii* are popular varieties at present. In the manipulation of tender perennials, there are often two methods of propagation, either of which may be better, according to the ideal in view. As a matter of general tendency, propagation by cuttings gives bloom that is earlier but not so continuous or profuse as by seeds. Salvias and verbenas are pronounced examples. On the contrary, cuttings must be depended on, as a rule, to keep the choicest varieties true to type, as a function of seeds in nature seems to be to produce more variation than can be attained by non-sexual methods of propagation, as by bulbs or cuttings. Salvias are also an example of plants that are particularly effective when seen at a great distance, and also of plants that are generally massed for unity of effect, and not mixed with others. Verbenas are commonly grown by them-

to secure a strong root development. Therefore, they should be ordered early, and planted in the latter part of October or first of November. The colors may be massed or mixed according to taste, the terms massed and mixed bedding referring to unity or variety of effect, and being applicable in each of the four main types mentioned above.

Opposed to this style of bed-

selves, but this is because they demand much room by reason of their trailing habit.

#### Subtropical bedding.

Summer bedding for subtropical effects employs chiefly cannas, musas, castor-oil plants, crotons, palms, ferns of coarser habit, screw-pines, dracenas, araucarias, elephant-ear caladiums, and, to a lesser extent, abutilon, acalypha, achyranthes, anthericum, *Carica Papaya*, sanchezia, and others. Cannas are by far the most popular at the present time, especially for mass-work. Sometimes the tall, purple-leaved old-fashioned, small-flowered types are used in the center or at the back of the bed, and the dwarf, modern, large-flowered types around the edges or in front. Frequently, massing with a single variety of canna is practised. Next to cannas in popularity probably come the crotons or codieums, — the broad-leaved types, as Queen Victoria, being better for this purpose than the narrower-leaved or simply curious kinds, as *Codiaeum interruptum* and *C. volutum*, which belong to fanciers' collections. For carpeting the ground in a croton bed, two variegated trailers can be used with good effect, the wandering Jew or tradescantia and *Oplismenus Burmannii*, which is familiar to gardeners as *Panicum variegatum*. The large leaves of bananas give a very rich tropical effect, especially if

492. Tudor rose pattern.

their marvelous growth from seed in a single season makes it one of the very best of all plants for rapidly filling up large areas temporarily. Grasses furnish an exception to the general rule that bedding plants are tender. There are some kinds of bamboos that are more or less hardy in the northern states, and these are bound to increase in popularity. Figs. 487, 488. A favorite combination of grasses for bedding is *Arundo Donax*, the giant reed, surrounded by eulalias. Grasses and their kind are particularly effective in aquatic groups.

No well-kept large establishment is complete without a pond or body of water in which aquatic plants are naturalized. For a more extended account of this attractive subject, see the article *Aquatics*.

There is a large class of tender material—as palms, screw-pines, the coarser ferns, dracenas, araucarias—a class of foliage plants that really does better outdoors during summer in a shady and sheltered position than indoors all the year round. In the more formal styles of ornamental gardening, such plants often form the nucleus of a subtropical bed, the large tubs of the palms being hidden by lower-growing plants, as begonias, or whatever may be left over from the spring operations. In less formal gardening, the tubs may be hidden by plunging them half-way into the ground and grading the sod, which has been previously broken, in such a manner as to conceal the tubs entirely. The

plants are arranged in a freer and more natural manner, and the outer fringe of begonias and the like may be dispensed with. The chief dangers to such plants are from the sun and wind. Palms once scorched or wind-whipped are ruined. Hence, a sheltered position on the north side of a building, or under the shade of trees, is usually the best spot for their summer vacation.

#### Carpet-bedding.

What is known as carpet- or design-bedding is the most formal and most expensive of all kinds of bedding, and employs plants that stand pinching and shearing, as coleus, achyranthes, alternanthera, lobelia, one of the dusty millers (*Centaurea gymnocarpa*,—*C. candidissima* will not bear the shears), and certain succulents of the hen-and-chickens type (as echeverias), and many others. The plants are started indoors, mostly by cuttings, and from very carefully selected stock. The terms "geometrical bedding" and "fancy bedding" are somewhat synonymous. Here belong the imitations of buildings and animals, the portraits of men, the lettered greetings to conventions, the calendars, floral clocks, and similar ingenuities.

The designs of carpet-beds are very numerous, but there are certain recognized standards. The diagrams (Figs. 489 to 494) give forms and planting material for a half-dozen unlike and regulated patterns, with harmonious color combinations. Forms of pattern-beds on the lawn are shown in Figs. 495, 496. A proper setting for pattern beds is indicated in Fig. 497. For designs and for extended cultural information, the reader is referred to the numerous German books on the subject, to Mottet's *La Mosaiculture*, and to a book published by Geo. A. Solly & Son, Springfield, Mass. This style of bedding requires the highest degree of technical skill, and is especially enjoyed by the Germans, whose gardeners excel in it.

The position of a bed is far more important than the style of bedding or the kinds of plants that are used. The natural school of landscape gardening, as opposed to the various schools of ornamental gardening, makes no objection to beds

in themselves, but dislikes their usual position. They are commonly given the most conspicuous places, where they must be seen, whether people like them or not. They should be in a place by themselves where they do not interfere with the quieter and larger pictures of the whole place. Sunken areas, as in Fairmount Park, Philadel-

phia, are particularly commendable; a flower-bed should not be in the middle of a large lawn, because it distracts the attention from the larger picture, and because the lawn is the canvas upon which the landscape gardener makes his picture. The chief merit of beds is their attractiveness and brightness, which accounts for their presence in parks and public places. On the other hand, they are expensive, and they are at their best only two or three months in the year, while a mud-hole in a lawn for nine months of the year is an unsightly object. Formal beds, especially of foliage plants, with their gaudy colors and unchanging monotony, are considered by some the most unnatural and the least artistic style of gardening. Nevertheless, they require a high degree of technical skill, which deserves appreciation.

495. Lawn bedding pattern.

#### General instructions.

A few practical suggestions may be given for making any bed. The soil should be rich and full of vegetable matter. If a foot or 18 inches of the surface soil is so poor that it must be removed, it may be replaced by two parts of fibrous loam and one of well-rotted manure, with some upturned broken sods in the bottom for drainage. The fall is the proper time to apply manure, and if the bed be thoroughly spaded over and left rough during the winter, the alternate freezing and thawing will fine both the soil and the fiber of the manure. Beginners nearly always fail to supply perfect conditions for watering. A midsummer mulch of half-rotted manure enables the plants to take all the moisture they need during the drought and to keep it. The soil should be in ideal condition before the plants are set into it,—mellow, rich, full of fiber, and of firm and uniform texture. Begin in the middle and work toward the edges. When the bed is finished, give it one thorough soaking, to settle the soil at the roots.

**BEECH:** *Fagus*.

ROBERT SHORE.

**BEES IN HORTICULTURE.** Bees pollinate the greatest number of flowers of any insects. To them, therefore, horticulturists are indebted for a service that is inestimable, but it is usually disregarded. The progressive horticulturist, however, today is awake to the situation and ready to utilize the honey-bee in an effort better to meet competition.

496. Lawn bedding pattern.

the stigma, which latter is the female organ. Many flowers, for satisfactory fertilization, require a foreign pollen, and it is through the agency of bees that this is usually supplied. The intricacies of the mechanisms and the means of pollination have been described by a host of writers, including Darwin and Müller.

There are two kinds of bees, solitary and colonial (social). Solitary bees live isolated and singly, seldom

becoming numerous. Among the colonial bees are the bumblebee and honey-bee. While the honey-bee may be classed as wild when colonies escape from apiaries, wild bees may be considered to include all bees other than the honey-bee.

While wild bees are sometimes numerous and may be observed at work on the apple, raspberry and many other flowers, the honey-bee, in most localities, probably outnumbers them. If it were possible to calculate the value derived from pollination by the honey-bee alone, these returns would without doubt far exceed the total income of beekeepers through their honey and wax. In the bee, therefore, there is a source of double income.

Among the cultivated plants in northern latitudes that are pollinated by honey-bees, are the apple, pear, plum, quince, peach, raspberry, blackberry and strawberry (to some extent), mulberry, pea, bean, currant, grape, squash, melon, cucumber and the cranberry. The value of the honey-bee in the cultivation of the cranberry was but recently recognized and is mentioned on next page.

While growers of fruits and vegetables have usually recognized that bees play an important part in their croppage, they have largely depended on the wild bees or bees in neighboring apiaries for service. There is,

497. Pattern beds in a formal setting.

however, some risk in this, because the seasons vary and the prevalence of insect- and bee-life varies from year to year.

It is well known that the prevalence of all wild life, plant or animal, is subject to fluctuations due to favorable and unfavorable environmental conditions. Some years in a locality there is a pest of mosquitos or house-flies. In succeeding years they may be few. It is so with the game birds and the fish of the sea; they are plenty or scarce from time to time. Bees also have their periods of ups and downs. When favored, they rise to the crest of prosperity and prevalence. It may be that disease enters a locality and reduces their numbers. Hard winters may also depreciate them so that in a year when they are needed for their service as pollen-bearers, they are at a low ebb. Fig. 498 illustrates the hypothetical curve of this fluctuation.

When the horticulturist realizes that he is depending on this fluctuating service of wild bees, he asks what he can do to overcome the unreliability and assure himself of a maximum crop or a more even crop. The recommendation would be to establish an apiary in proportion to the size of the orchard or garden. This eliminates any dependency upon wild bees or honey-bees from neighboring apiaries. Yet their additional service will do no harm. It is far better to over-supply an orchard with bees during the blooming period than to have a scarcity. Furthermore, the cost of the small apiary is infinitesimal as compared with the possible benefits and returns.

It should also be remembered that during fruit-bloom particularly, weather conditions often prohibit free flight of bees. Hence they should be near at hand to perform their service. Numerous observations are on record in which orchards were successfully fertilized when the bees had less than a quarter of a mile to fly, while more distant orchards bore no crops. Thus the apiary in or adjacent to an orchard will safeguard failure.

A specific instance of the importance of bees to the practical orchardist, is shown in an observation on two orchards of about equal acreage in a western "pocket" in the foothills of an admirable fruit land, well drained and protected from frost. One grower secured large crops, while his neighbor secured none, although his fruit trees were of the same age and blossomed heavily each spring. The owner, in despair of financial ruin, called for assistance upon the State Experiment Station. A specialist, who was a pomologist and entomologist, investigated the two entirely comparable orchards, but was about to return without solving the problem when the question of bees arose. Upon inquiry it was asserted that no bees had been maintained for either orchard. Going over the ground more carefully, however, the specialist found in a neglected corner of the fruiting orchard, a fallen log partially sunken in the damp land. This sheltered a very large colony of bees; to it is attributed the success of the orchard. The following season bees were provided in the orchard which had previously failed, with the result that the owner netted \$3,800 on his crop.

#### *Special services of bees.*

*Various fruits.*—The honey-bee has been known to work the strawberry although it does not always frequent it. There is, however, a particular affinity in the raspberry for bees. One of the sources of the finest honey is the wild raspberry. The blackberry is less frequently visited. Plums benefit materially.

*Cranberry.*—Recently investigations have shown the bees to be of prime importance in the setting of cranberries. In cranberry-growing in Massachusetts, owners are maintaining their own apiaries. It may be desirable to have one colony for every two acres. The growers of melons use colonies of bees on their plantations with most marked success. Similarly, cucumber-growers for pickling-houses and squash-growers regularly maintain bees. General market-gardeners also believe in the benefits derived.

*Apple and peach orchards.*—Apple and pear crops as well as peach and plum are, without doubt, more even, larger and more constant when bees are kept. In Vermont it has recently been noticed that the largest apple crops occur in the vicinity of the commercial apiaries. It is fast becoming the custom among commercial growers to maintain their own apiaries adjacent to or in their orchards. Some advocate a colony of bees for every fifty trees.

*In greenhouses.*—For the fertilization of vegetables and fruits in greenhouses, bees are of material service, having largely done away with the use of the camel's-hair brush, impossible for commercial growers. For example, in Massachusetts, one grower of greenhouse cucumbers uses upwards of eighty colonies a year. The total number used annually in the state by greenhouse cucumber-growers exceeds 2,000 colonies. It is believed by some that tomatoes in the greenhouse benefit to some extent by the service of bees.

#### *The alleged injury to fruit by bees.*

Occasionally it is alleged that bees damage an orchard. It might be concluded when bees are seen upon peaches, grapes or pears, sucking at the flesh, that the bee is injurious. On the other hand if this act could have been traced, it would have been found that something other than a bee had first pierced the skin of the fruit. Investigation shows that wasps and birds do this,

or that a fungus may disintegrate the skin. In some such break in the skin the honey-bee can make a start; but to the satisfaction of all beekeepers and most orchardists, it has been proved by experiments and demonstrations that the honey-bee is physically incapable of puncturing a sound fruit. Thus, the injury by bees to fruit is a misconception; the news should be spread by successful orchardists.

#### *Securing of bees.*

Bees are available to horticulturists in several ways. A small number of colonies is sometimes hired for a period of a few weeks, during the blossoming period of the crop. Growers occasionally induce beekeepers to establish an apiary in their orchards by granting them privileges. Bee-keepers sometimes approach orchardists for the location of the apiary. The more thoughtful grower, however, considers it advisable to own his bees. These he maintains himself or hires kept by a practical apiarist. The practice is growing in favor, especially among moderate-sized orchardists or cranberry-growers, of hiring a practical apiarist to maintain the colonies on several adjacent farms. This coöperative plan insures a maximum efficiency of the colonies at a minimum cost and without burdening the horticulturist with additional detail. Those who use bees in

498. Hypothetical curve illustrating the fluctuation of wild-bee life, their periods of "ups" and "downs." Dotted line illustrates high efficiency secured by maintaining an apiary.

greenhouses will find it advantageous to maintain colonies rather than to purchase annually.

In buying bees it is particularly essential to secure disease-free stock. Bees are subject to at least two prevalent diseases, known as "American foul brood" and "European foul brood," to which they succumb rapidly. The inexperienced, therefore, should secure information and ascertain that the bees have been inspected for disease, when this is possible. Should disease set in, a considerable loss, both in bees and to the orchard, might result in a short time. Information concerning diseases can usually be had through the experiment stations or agricultural colleges as well as the United States Department of Agriculture.

#### *Manipulation of bees.*

There are numerous books and bulletins upon the manipulation of colonies. A few fundamental features are: Always keep the colonies strong; secure an amiable race so that the bees may be handled agreeably; keep the colonies in hives from which the combs may be removed; eliminate swarming; give adequate protection in winter; feed when necessary.

If the inexperienced grower is to manipulate his own bees, it is advised that he begin with a small number of colonies, say not more than five.

If the bee-moth becomes prevalent in the hive, it is a sign that something is radically wrong with the colony. An experienced apiary inspector always suspects the presence of disease when moths are found.

BURTON N. GATES.

**BEET.** A set of garden vegetables, grown for the fleshy roots and a few sorts for the thickened midribs; and some kinds in the ornamental garden for the highly colored foliage.

There are 4 or 5 species of the genus *Beta*, which are

sometimes cultivated under the name of beet, but *Beta vulgaris*, Linn., is the only one of practical importance. From it all our common garden varieties are derived. According to DeCandolle, the aboriginal slender-rooted species is found in sandy soil, and especially near the sea, throughout southern Europe, and on nearly all the coasts of the Mediterranean. It also occurs as far eastward as the Caspian Sea and Persia. "Everything shows

that its cultivation does not date from more than two or three centuries before the Christian era." It is now highly improved, principally in the one direction of large and succulent roots, and is much esteemed in all civilized countries. See *Beta*.

The beet grows at a low temperature and thrives best, therefore, in the cooler parts of the country. It is also an important winter crop at the South and an early spring crop at the North. The young plants will stand light frosts and after two weeks will stand fairly heavy frosts.

499. Bassano beet.

With the extension of glasshouse gardening, beets have come to be one of the important greenhouse crops. They are not usually made a main crop, however, but are grown between other crops, such as lettuce, beans, or even tomatoes. They are sown very thick and when the young plants begin to crowd, they are thinned out and the thinning sold for greens. As beets thrive best at relatively low temperatures, they may first be grown in a lettuce-house or other greenhouse having a temperature of 60° to 70°, rather than in a house piped for tomatoes or cucumbers.

The beet is grown exclusively from seed. Most table-beet seed for use in the United States is produced in Europe. It is possible, of course, for any gardener to grow his own seed, but in order to do this the roots must be taken up before the crown is exposed to severe frost, and carried through the winter in cool and moist but frost-proof storage, and planted in the garden the second year. Seed stems run up to the height of 4 feet. When the seeds are ripe the tops are cut and put in a warm storage house to dry. When fully dry the seed is winnowed out. Seed is usually sown where the crop is to grow, although the plants are easily transplanted. The transplanting is sometimes undertaken, especially when beets are to be grown as a catch-crop or intercrop in greenhouses.

#### Varieties and types.

Some of the most popular varietal types of the garden beet are: *Bassano* (Fig. 499).—Flesh white and light red mixed; an old-time early variety, now less grown than formerly. *Crosby*.—Slightly oblate, red flesh, excellent for general purposes, including forcing. *Early Blood Turnip*.—Rich, deep blood-red, flattened turnip-shape; an old and well-known sort. *Edmand*.—Moderate size; handsome, rounded, smooth, deep red; good grain and flavor; not quite first-early. *Eclipse*.—Uniformly globular, bright red; fine-grained and sweet; one of the best quick-growing early beets. *Egyptian Turnip*.—Tops quite small; roots fair size, rich, deep red; a standard early variety.

For field culture of culinary beets, the long-rooted varieties are chiefly used. These are sown in the field as soon as the weather is settled, in rows far enough apart to allow of tillage by horse. Most of them require the entire season in which to mature. They are grown mostly for storing for winter use. They were once grown for stock, but the mangel-wurzels give much greater yields. The various types of Long and Half-long Blood beet (Fig. 500) are chiefly used for field culture.

Favorite varieties of mangel-wurzels are Golden Tankard, Golden Yellow Mammoth, Mammoth Long

Red. Several sorts of sugar beets, mostly imported from Germany, are being grown in divers places in America. Of chard, there are few selected varieties offered in America.

The varieties of *Beta vulgaris* may be conveniently divided into five cultural sections, though the distinctions are somewhat arbitrary and of no fundamental importance. These sections are as follows:

1. GARDEN BEETS. Varieties with comparatively small tops; roots of medium size, smooth, regular and fine-grained; mostly red, but sometimes whitish or yellowish.

2. MANGEL-WURZELS, or MANGELS. Large, coarse-growing varieties, with large tops and often very large roots, the latter frequently rising some distance out of the ground; rather coarse-grained. Extensively grown for stock-feeding. See *Cyclo. Amer. Agric. Vol. II, p. 539* (Root Crops).

3. SUGAR-BEETS. Sometimes said to belong to another species, but doubtless to be classified here. Rather small-growing varieties, with medium tops; roots small to medium, usually fusiform, smooth, nearly always yellowish or whitish. See *Cyclo. Amer. Agric. Vol. II, p. 588*.

4. CHARD, or SWISS CHARD. Varieties with comparatively large tops, broad leaf-blades and very large, succulent leaf-stems, which are cooked and eaten somewhat like asparagus. The thrifty, tender young leaves make a very excellent pot-herb. Chard has sometimes been referred to a separate species, *Beta Cicla*, but should be included with *B. vulgaris*. See *Chard*.

5. FOLIAGE BEETS. A race which has been developed to produce luxuriant foliage of many colors and varied markings. Of such varieties are the Brazilian, Chilian, Victoria, and Dracena-leaved. The ribs of the leaves are usually beautifully colored. Where the leaf-blight fungus is not serious, these foliage beets make excellent borders when strong and heavy effects are desired, and they are excellent for bedding. Raised from seeds, as other beets are; roots may be kept over winter.

#### Cultivation.

Young beets constitute one of the most important early crops in truck-gardening. Many acres of them are grown near all the city markets, and as they bear transportation well, they are often grown at comparatively remote places. Large quantities are shipped early from

500. Half-long Blood beet.

Norfolk, Va., and from other southern points to northern markets. Like all root crops, the beet needs a loose, light, fresh, clean, rich soil, which must be in the best condition of tillage. No fermenting manure should be used, but instead fully rotted barn manure, with some good potash fertilizer. Light applications of nitrate of soda often produce marked beneficial effects. The seed for the first crop is sown early in spring, as soon as the soil can be well worked. When intensive garden-

ing is practised, the drills may be as close as 1 foot apart, in which case the young beets are thinned to 6 inches apart in the row. But in ordinary gardening, it will be found most convenient to run the rows 2 to 3 feet apart, allowing cultivation with the horse. The plants in such rows can be left 4 inches apart at thinning time. The thinning is done when the young plants are large enough to be pulled for "greens," for which purpose they find a ready market. Beets are also grown in quantities as a fall crop, and are stored for winter use. When this is to be done, the seed is sown in June, and the plantation is managed in all respects like the spring sowing. When the young roots are ready for the early market, they are pulled and tied in bunches of five or six. The fall crop is pulled soon after the first frost, the tops are removed, and the roots stored in pits or root cellars.

#### Marketing.

Greenhouse beets and early beets are usually bunched for market, three to six together, according to size. They are bunched together tightly with a string about the tops. All beets should be thoroughly washed before marketing. Considerable quantities of late beets and field-grown stock are sold in bulk, like potatoes. In this case the tops are cut off. Late-grown beets may be stored over winter in the same manner as potatoes. They are often buried in the fields in pits, but may be kept in a good cellar or storage house. The yield of mature beets varies from 200 to 500 bushels to an acre, 300 being an average yield.

#### Insects and diseases.

There are many species of insects that feed upon beets, but flea beetles are about the only ones of importance. These may be poisoned by spraying with paris green or arsenate of lead, and they are driven away in many cases by the use of bordeaux mixture which is also the most important preventive of leaf-spot. This leaf-spot is perhaps the worst disease which attacks beets, but this is more common upon the sugar-beets in the field than upon the more common varieties. The potato scab, very common on potatoes, is found also on beets, and as this disease lives in the soil from year to year, it is a bad practice to grow beets after a crop of potatoes.

F. A. WAUGH.

**BEGONIA** (named after Michel Begon, superintendent at St. Domingo, 1638-1710, a French promoter of botany). *Begoniaceæ*. **BEGONIA**. ELEPHANT'S EAR. BEEFSTEAK GERANIUM. A various group, ranging from hothouse to conservatory and window-garden subjects, many of them grown primarily for foliage, others for the showy bloom; treated mostly as single pot-specimens, but some kinds used for bedding.

More or less sappy or succulent herbs or undershrubs, having the st. in some cases reduced to a thick rhizome, in others to a distinct small tuber, while a few others possess a semi-tuber in which there are a number of closely set scales or suppressed lvs., resembling bulbs: lvs. variable, alternate, more or less unequal-sided, entire, or lobed, or toothed, ovate-acuminate, orbicular or peltate: fls. monœcious (bisexual variations are known: Dümmer, *Annals Bot.* xxvi. 1123), asymmetrical, usually in axillary cymes, the males usually with 4 parts, of which 2 are mostly small, the females with 5 (rarely 2), pink, white, rose, scarlet, yellow, and all shades of these, being represented; stamens numerous; filaments free or united at the base; styles 2 or 4, free, sometimes connate; stigmas branched or twisted like a corkscrew; ovary inferior: fr. usually a 1-3-winged caps., which is often colored; seed numerous, very minute.—The genus *Begonia*, with 400-500 species in warm countries around the globe, gives the name and definition to the *Begoniaceæ*. Only three other genera are recognized: *Hillebrandia*, with 1 spe-

cies in Hawaii; *Symbegonia*, 1 little-known species in New Guinea; *Begoniella*, 3 species in Colombia. The begonias are exceedingly variable, the genus running into about 60 well-marked sections, but the intergradations are so many and the essential floral characters so constant that it is impracticable to break up the great group into separate genera.

The begonia is one of the great groups of cultivated ornamental plants. Very many species have been introduced, and there are numberless hybrids and variations. The most popular single begonia is now probably the wonderfully floriferous *Gloire de Lorraine* (Fig. 505). The foliage begonias are of many original kinds, and the numerous hybrids and variations have given great choice to the cultivator. *B. Rex* is the chief basis of the foliage races. Many cultivators are unaware of the possibilities of the *Rex* derivatives, because they grow them in pots (for commerce) on benches, whereas the singular and characteristic results are secured by growing them in the earth against greenhouse walls or in rock pockets below the benches (Plate XIV).

Because of the great numbers of interesting forms, begonias have appealed strongly to collectors and fanciers. In recent years, however, the collections have been passing out in the large private places; and most dealers now carry only a few standard kinds (mostly modified cultivated forms), in addition to the florists' bedding and garden sorts and a general mixed stock of tuberous kinds. The following botanical account, therefore, does not accurately represent the present state of the begonia trade. It is to be regretted that the fanciers' collections are not kept: and it is partly in the hope that the desire for collections will return that this rather full treatment is given of the main species and stem-groups now in cultivation.

The foliage begonias of the *Rex* type are subject to an insidious disorder, affecting the leaves and eventually the entire plant. The remedy seems to be to discard all suspected stock and to propagate from wholly healthy plants, or to grow them out of it by planting them in a shaded airy greenhouse bench for a summer and potting again in fall.

The interest in begonias centers in their use as ornamental subjects. It is said that the stalks of some of the species are used as the leaf-stalks of rhubarb are used. The rhizomes of many species, particularly those from South America, are bitter and astringent and are employed locally for certain fevers and for syphilis. Some species contain purgative principles. The sour sap of one of the Asiatic species is said to be used for the cleaning of weapons.

The first begonia was introduced into England in 1777, *B. nitida*. Since then, about 200 have proved of value to the horticulturist. Few other plants have been improved or varied so rapidly, there being thousands of variations now in cultivation, displaying the most gorgeous colors in their flowers and beautiful coloring in their leaves. The development of the modern race of hybrid tuberous begonias followed the introduction of *B. Veitchii*, *B. rosæflora*, *B. Davisii*, *B. boliviensis*, *B. Pearcei* and others after 1860. The geographical distribution of begonias is very disjunctive and localized. They are indigenous to Mexico, Central and South America, Asia, and South Africa. They seem to have no genetic relationship with other plants now living. For literature, see Dryander, *The Genus Begonia*, *Trans. of the Linn. Soc.*, Vol. I, 1791; Klotzsch, *Begoniaceen-Gattungen und Arten*, 12 plates, 1855 (*Abh. Ak. Berlin*); DeCandolle's *Prodromus*, 15, 1, 1864; and floras of regions in which begonias are native.

L. H. B.

#### General culture and propagation.

For horticultural purposes, the begonias may be arranged in four groups: The socotrana or semi-tuberous set; the tuberous-rooted; the foliage kinds, mostly

rhizomatous; and the fibrous-rooted. The bedding begonias are mostly of the fibrous-rooted section, particularly in the *Semperflorens* group, although the improved tuberous kinds may be used for this purpose in special places.

501. Young plants starting from the incisions on a begonia leaf.

leaf-mold than the fibrous-rooted, and a temperature of 65° to 70° in the daytime and 60° at night. Of *Gloire de Sceaux* and some others, plants two years old will be found best for decorative purposes. For special notes on *B. socotrana*, see the treatment of that species, page 473.

(2) The tuberous begonias are grown in pots, boxes or baskets, under glass, or as bedding plants in a shaded border. If the plants are intended for pot-culture in the greenhouse, it is best to use the tubers. For early flowering, start the tubers in February or March, either in small pots or shallow boxes. The soil may be composed of loam, sharp sand and leaf-mold, and the temperature about 60° to 65°. When the plants are ready for repotting, well-rotted manure may be added, and when the roots have taken a fresh hold a cooler temperature may be maintained. For bedding purposes, seedling plants, as well as tubers, may be used, providing they are of a first-class strain. Tubers are preferred if early-flowering plants are desired. For further cultural notes, see the discussion on page 471.

(3) The Rex begonias are grown entirely for the beauty of their foliage. They may be propagated by means of either shoot- or leaf-cuttings, the latter being the better when plants have to be raised in quantity. Large and well-matured, but still healthy and vigorous leaves may have the principal nerves cut on the under side. The leaf is then pegged or weighted down on the surface of a well-drained propagating bed. If carefully shaded, roots will be formed at every cut, a tiny leaf will follow (Fig. 501), and the little plants may be inserted singly in small pots. Another method is to cut the large leaves into triangular parts, with a bit of the main petiole at the tip of each, and insert the pieces about 1 inch, with the lower or thickest end of the rib downward (Figs. 502, 503). Still another method is to cut the leaf in two, across the veins, and stand it edgewise in the propagating bed. The young plants may be potted-up into small pots, using a light, porous, sifted soil. Keep shaded in a low house with a moist atmosphere. The soil may be gradually made coarser with each potting until in the final shift; an unsifted compost of two parts loam, one part leaf-mold, one part well-rotted manure, and one part sand, is used, adding a sprinkling of lime. While watering, avoid wetting the leaves as much as possible, and keep

502. Triangular leaf-cutting of begonia.

large, well-developed plants in a shaded house, with plenty of ventilation day and night during the summer.

(4) The fibrous-rooted begonias comprise such species as *B. nitida*, *B. semperflorens* var. *gigantea*, *B. albopicta*, *B. Haageana*, and *B. Duchartrei*. Of these, cuttings taken from clean, healthy stems in spring will strike readily in an ordinary propagating-box or bench, and if potted-on, as they require root-room, will make fine plants for late winter and spring flowering. As

soon as one neglects good treatment, especially in regard to light, fresh air and fresh soil, the red spider, a physiological disease appearing like rust, and the dreaded nematodes, will soon attack them and give them a sickly and stunted appearance. They require a temperature of 55° to 60° at night and 65° to 70° in the daytime. The plants should be kept close to the glass in the early stages of growth, on account of the tendency of many of the varieties to send out rather long shoots. A good compost is three parts loam, one part well-rotted manure, and one part sand.

While begonias in general are injured by too strong sunshine during summer, they are benefited by all the sunshine they can get during the winter and early spring months. Strong sunshine, however, pouring through imperfect glass upon wet foliage, is liable to blister the leaves of any begonia. Such species as *B. Dregei* and *B. weltoniensis*, which produce at their base a thickened, fleshy stem like a potato, may be propagated either by division or by cuttings. Many kinds of the fibrous-rooted and rhizomatous sections can be grown by amateurs, and make excellent house-plants, especially *B. manicata*, *B. coccinea*, *B. speculata*, *B. argyrostigma* var. *picta*, *B. riciniifolia*, *B. heracleifolia*, *B. incarnata*.

ROBERT SHORE.

#### Begonia Gloire de Lorraine.

*Begonia Gloire de Lorraine* (Fig. 505) was raised by Lemoine by crossing *B. Dregei* and *B. socotrana*, and is one of the most useful and beautiful decorative plants introduced. If large specimen plants in 10- or 12-inch pans are desired, propagating should be begun about November or December of the year previous, as these plants are generally at their best about Christmas time. The best plants are obtained from leaf-cuttings. Select medium-sized, well-ripened leaves, cut off with a sharp knife, insert in a bed of sharp sand in a temperature of 70° and space them far enough apart, so that they do not touch one another. The propagating-bed should be at least 2 inches deep, but the stems should not be buried so deeply that the leaf lies on the top of the bed. These precautions prevent damping off. A further preventive against damping off is to dust powdered charcoal over the bed after the cuttings have been thoroughly watered. The leaf-cuttings of *Gloire de Lorraine* are far superior to shoots that start from the base of a cut-back plant, the leaf-cutting having greater vigor and breaking more shoots from the base of the plant. The leaf-cuttings will root in three weeks in the temperature recommended above, but they should be left in the sand until they begin to throw up shoots from the callus formed at the end of the leaf-stem, after which they should be immediately potted in 2-inch pots, in equal parts of fibrous loam and leaf-mold, with about a fourth part of charcoal. Never allow the plants to become pot-bound until they have attained the desired size, and for all future pottings use equal parts of the fiber of loam, half-decayed flaky leaves, well-rotted cow-manure or horse-droppings, and a fourth part of charcoal. Use this compost as rough as can be conveniently worked around the plant while potting. During the summer, they should be grown in a rather humid atmosphere near the glass, always lightly shaded from the sun until they begin to flower. Pinch the shoots two or three times during the season as this encourages breaks from the base of the plant. When well rooted in the final shift, waterings with manure-water will be beneficial. When the plants begin to flower, they should be neatly staked with thin twigs,

503. Plant arising from the base (or tip) of a triangular leaf-cutting.

504. *Begonia socotrana* ( $\times \frac{2}{3}$ ). No. 1.

by cuttings it can be done. Shallow boxes or seed-pans may be used in which to sow the seed about the beginning of February. They should be well drained and filled with a compost made up of equal parts of peat, leaf-mold and about a fourth of charcoal. As soon as the plants are large enough to handle, prick them out about 2 inches apart in the same soil as above, place them close to the glass, but always shaded from the bright sun, and in a moist atmosphere. When they have grown close together, transfer them to  $3\frac{1}{2}$ -inch pots, the best soil to use from now on being a spent mushroom bed, adding about a fifth part of charcoal. A 6-inch pot is generally large enough for the first season, and when they are well established in these pots should be kept as cool as possible. A house facing north is the best place for them during the summer, and all the air possible may be admitted night and day. On no account allow these plants to suffer for lack of water until fall, when they will begin to show signs of ripening off. During their growing period, they may be stimulated by frequent applications of cow-manure water, and soot diluted in water, an ordinary handful to two and a half gallons of water; water three times with clean water, and alternately with the other two. When signs of ripening begin to show, gradually withhold water until the growths decay, and then place the pots on their sides under a bench in a greenhouse where the temperature keeps around  $40^{\circ}$ . Be sure they are in a position where

unless desired for hanging plants, when they may be allowed to droop around the pan. When in flower they should be in a light airy greenhouse with a temperature of  $45^{\circ}$  by night. These plants are subject to mealy-bug and may be fumigated at intervals of two weeks with hydrocyanic gas.

GEO. F. STEWART.

### Tuberous begonias.

The tuberous-rooted begonias, which are every year becoming more popular, both as pot-plants, and for bedding out-of-doors, are the result of crossing several different species differing considerably in habit, and are easily cultivated. They are raised almost wholly from seed, and good strains in different colors may be obtained from any reputable seed firm. However, if one wishes to

increase these plants

water does not reach them. The tubers will be good for several years, but the best plants are in their second year. The plants may be started at intervals, having an earlier and a later lot. For bedding out in partial shade, these plants have no equals. Start the tubers in flats about the end of April, have the bed heavily manured and the soil level with the surface of the ground, as the roots run near the top of the ground, and consequently they have to be watered frequently. The top of the bed should be always moist, a mulching of well-rotted manure being of great assistance in retaining the moisture. Plant about a foot apart, all of one color, unless great care is exercised in blending the brilliant colors so that they do not clash.

GEO. F. STEWART.

## HORTICULTURAL ARRANGEMENT OF SPECIES.

This arrangement often throws together species of no close botanical relationship, but it will aid the cultivator to understand the genus.

I. SPECIES BULBOUS OR ESSENTIALLY SO.  
*socotrana*.

## II. SPECIES TUBEROUS.

- A. Plant stemless, lvs. springing directly from the crown or tuber (*Davisii*, *rosæflora*, *Froebelii*, *Veitchii*, *octopetala*).  
 AA. Plant with sts., more or less branching.  
 B. Lvs. narrow (lanceolate to ovate-lanceolate) (*boliviensis*, *Sutherlandii*).  
 BB. Lvs. broad (ovate to cordate-ovate) (*Pearcei*, *Clarkei*, *Evansiana*, *gracilis*, *Dregei*, *weltoniensis*, *fulgens*).  
 BBB. Lvs. orbicular (*Baummannii*).  
 BBBB. Lvs. various, mostly broad-ovate at base, acuminate (*tuberhybrida*).

## III. SPECIES RHIZOMATOUS.

- A. Plant creeping, trailing, or climbing (*glaucophylla*, *scandens*).  
 AA. Plant upright, often diffuse.  
 B. The picture-lvd. species, grown for the foliage, which is large and prominent and blotched, strongly colored, blistered, or otherwise illustrated. The *Rex* set, and others.  
 C. Lvs. oblique, lobed at the base, not peltate (or only slightly so) (*Rex*, *xanthina*, *Griffithii*, *Rajah*, *Augustinei*, *dadalea*, *speculata*, *decora*, *imperialis*).

- CC. Lvs. markedly peltate (*modica*, *Gentilii*, *Binotii*, *goeocensis*).  
 BB. The essentially plain-lvd. rhizomatous kinds, although some of them are grown chiefly for foliage.  
 C. Lvs. prominently lobed, or parted or even divided (*ricinifolia*, *heracleifolia*, *Sunderbruchii*, *rubella*, *Verschaffeltiana*, *heraclei-cotyle*).  
 CC. Lvs. lanceolate to ovate or cordate-ovate to orbicular, not deeply lobed, often entire, and sometimes peltate.  
 D. Foliage small, the lvs. less than 2 in. wide (*hydrocotylifolia*).  
 DD. Foliage of usual or large size.  
 E. The lvs. peltate (*Feastii*, *nelumbiifolia*, *conchæfolia*, *Lubbersii*, *albo-coccinea*).  
 EE. The lvs. not peltate (*manicata*, *leprosa*, *magnifica*).

IV. SPECIES FIBROUS-ROOTED (*Rhizomes* small or O.)

- A. The herbaceous kinds—the plant small, succulent, never becoming very tall or woody (*semperflorens*, *gigantea rosea*, *Carrierei*, *Erfordii*, *Lyncheana*, *Lucianæ*, *Corbeille de Feu*).  
 AA. The woody or shrubby kinds, usually much branched when mature, and often tall.  
 B. Kinds slender, upright, small-leaved, mostly smooth, green or nearly so: lvs. many and usually not more than 1 in. across.  
 C. Fls. pink or red (*fuchsoides*, *Ingramii*, *Digs-welliana*, *incarnata*, *ascotiensis*).  
 CC. Fls. white, or tinted white (*foliosa*, *knowsleyana*, *acuminata*, *albo-picta*).  
 BB. Kinds low-growing, diffuse (*Schmidtiana*).  
 BBB. Kinds stiff, succulent white-scurfy (*peltata*, *venosa*).  
 BBBB. Kinds mostly tall and erect, some of them becoming 8 ft. high, distinctly shrubby and bushy.  
 C. Lvs. compound, or divided (*luxurians*, *Hemslayana*, *platanifolia*, *digitata*, *carolinæ-folia*, *diadema*).  
 CC. Lvs. not compound, although sometimes strongly notched or even lobed).  
 D. Whole plant hairy, or at least so much so as to give it the appearance of being a rough or pubescent species.  
 E. Foliage light green and plant pubescent (*ritifolia*, *Engleri*).  
 EE. Foliage markedly colored above or beneath, or both.  
 F. Fls. white (*echinosepala*, *erythrophylla*, *Scharfiana*, *Duchartrei*).  
 FF. Fls. colored (*Haageana*, *Credneri*, *Alleryi*, *Margaritæ*, *metallica*, *cathayana*, *deliciosa*, *laciniata*).  
 DD. Whole plant smooth or becoming so (a few hairs perhaps remaining on the lvs.), or so much so as to give it the appearance of being a glabrous species.  
 E. Lvs. medium to large, very broad, fleshy or thick, entire, often peltate (*sanguinea*).  
 EE. Lvs. medium size, stiff, green and shining, often elongated, mostly undulate or notched.  
 F. Fls. white (*angularis*, *ulmifolia*, *longipes*, *undulata*, *kewensis*).  
 FF. Fls. colored (*nitida*, *Teucheri*, *Bismarckii*, *carminata*, *polyantha*, *coccinea*).  
 EEE. Lvs. medium to large, the margins strongly toothed, incised or lobed.  
 F. Fls. white (*Madame de Lesseps*, *olbia*).  
 FF. Fls. colored, varying to tinted white (*argenteo-guttata*, *maculata*, *Thurstonii*, *dichroa*, *coronata*, *phyllomanica*, *President Carnot*, *lucerna*).

## I. BULBOUS BEGONIAS, AND SEMI-BULBOUS OR SEMI-TUBEROUS DERIVATIVES.

1. *socotrana*, Hook. Fig. 504. A winter-flowering species: st. annual, stout and succulent, forming at the base a number of closely set scales or suppressed lvs. resembling bulbs: lvs. dark green, orbicular, peltate, 4-7 in. across, center depressed, margin recurved,

crenate: fls. all male except the terminal one of each branch of the cyme, in terminal few-fl. cymes, bright rose G.C. II. 15:8. B.M. 6555. Gn. 21:163; 49:426 (as *B. Gloire de Lorraine*). J.H. III. 51:317. R.H. 1906, p. 130; 1909, p. 426. A.F. 13:587, 588.—Bulbs or semi-tubers were brought from the hot sandy island of Socotra by I. B. Balfour, and grown at Kew in 1880. The species was first described in *Gardeners' Chronicle*

in 1881, and in the same year in *Botanical Magazine*. See also Balfour, *Botany of Socotra*, p. 102, 1888 (Vol. 31, Roy. Soc., Edinburgh). An early study of the nature of the bulbs by Duchartre will be found in *Bull. Soc. Bot. de France*, 12 (1885).—This excellent plant requires to be grown in a light position in a stove to develop at its best. The bulbs should be shaken out of the old soil in Sept. or Oct. and potted up in a light soil, rich in humus, and placed in heat and moisture, and, when well established, should

507. *Begonia Davisii* ( $\times \frac{1}{4}$ ). No. 6.

be liberally supplied with manure-water. The fls. appear during the winter months, after which the plant dies down, forming a number of large resting buds or bulbs; the pots should then be placed in an intermediate temp. and be kept nearly dry until the following growing period comes round. On account of its habit of producing fls. in winter, this species has been largely used by the hybridist in the production of a race of winter-flowering begonias, of which there are many named varieties.

Following are leading *Socotrana* derivatives:

2. *Gloire de Lorraine* (*B. socotrana*  $\times$  *B. Dregei*). Fig. 505. One of the finest hybrid begonias ever raised: lvs. small, nearly regular, pure green: fls. almost exclusively male, 4-petaled, large, borne in broad panicles, covering the whole superior part of the plant, rose-colored, not deciduous. Gt. 42, p. 111. A.F. 12:842. G.F. 5:247.—Although *B. socotrana* is semi-bulbous and *B. Dregei* has a thickened rhizome, the hybrid forms show neither, but the base of the st. throws out many shoots, which can be separated and insure the multiplication of the plant. Intro. by Lemoine in 1892.—There are several forms of this plant now in cult. *Rothschilts* variety has larger and darker colored fls. than the type. *Turnford Hall* is a form with white fls. *Caledonia* also has white fls. but is far inferior as a garden plant to that of *Turnford Hall*. *Glory of Cincinnati*, a form with very lasting large satiny pink fls., is a seedling from *B. socotrana*  $\times$  a sport of *Gloire de Lorraine*: it bloomed first in Dec., 1908, and was intro. to trade in 1910 (J. A. Peterson).

3. *Gloire de Sceaux* (*B. socotrana*  $\times$  *B. subpeltata*). Fig. 506. Plant stout, half shrubby, erect, vigorous, compact, will form a plant as much as 8 ft. high in a year with good cult. and produce quantities of its large rose-colored fls. over a period of several months: lvs. dark metallic green, thick, large, red beneath, veins red above, suborbicular, slightly oblique: fls. profuse, beautiful rose-pink, shiny, females the last fl. on the cyme. Fls. from Dec. till May. R.H. 1884:516. G.F. 7:185.—Intro. in 1885.

4. *Triomphe de Lemoine* (*B. socotrana*  $\times$  *B. Roezlii*). St. herbaceous, spreading, then erect and branching into numerous flowering branches: lvs. large, coriaceous, orbicular, somewhat oblique, margins slightly crenate, 6 in. diam.: fls. in dichotomous cymes from axils of lvs., rose-carmine, female fls. exceedingly rare, males very profuse, plant resembling a large bouquet when in full bloom. G.F. 2:557.—Intro. by Lemoine in 1887. Retains its fls. after they are withered, a rare occurrence in begonias. Another hybrid from the same parent is *Triomphe de Nancy*, with fls. rich yellow in the center, double, and the outer petals of a paler hue.—Intro. 1888.

5. *incomparabilis*, Hort. (*B. socotrana*  $\times$  a garden tuberous form). Lvs. large, with the showy, well-formed orange-red fls. standing well above them. R.B. 33:60.

## II. TUBEROUS BEGONIAS, the plant passing the winter as a dormant tuber Nos. 6–30.

### A. Plant stemless: lvs. springing directly from the crown or tuber.

6. *Davisi*, Veitch. Fig. 507. Lvs. ovate-cordate, dull green, thinly hairy, above and below, upper side lighter veined and under side red, petiole short: peduncles, pedicels and fls. bright red. Peru. B.M. 6252. F.M. 1876:231. G.C. II. 15:669.—A favorite with hybridists, because of its rich coloring and its free flowering. It has given rise to numerous dwarf, erect-habited garden forms, with small but brightly colored fls.

7. *rosæflora*, Hook. Stout: petioles, scapes, bracts, and stipules bright red: lvs. green, 2–4 in. wide, on stout, hairy petioles, 2–6 in. long, orbicular, reniform, concave, margins lobed, red, toothed: fls. 2 in. across, rose-red. Andes of Peru, 12,000 ft. Intro. in 1867. B.M. 5680.—Light-colored seedlings of this species gave rise to *Queen of Whites*, put into commerce in 1878, and apparently an important factor in subsequent garden forms of the same color. The species itself is probably not now in cult.

8. *Froëbelii*, A. DC. More or less hairy: lvs. numerous, cordate, acuminate, green, covered with fleshy, purplish hairs: fls. in tall, lax, drooping, branching cymes, brilliant scarlet, large. Late autumn and winter. Ecuador. J.H. III. 32, p. 33. Journ. Roy. Hort. Soc. 19, p. xcii. Gn. 12, p. 376. Intro. about 1872–3 by Otto Froebel of Zurich.—A beautiful flowering plant, useful for conservatory work in winter. Var. *vernalis*, Hort., hybrid (*B. Froëbelii*  $\times$  *B. Dregei*), similar to type; intro. by Deleuil in 1880. Var. *nana*, Hort. Very dwarf: fls. dark scarlet.

9. *Veitchii*, Hook. Loosely hairy: st. very short or practically none, thick, fleshy, green: lvs. orbiculate, cordate, lobed and incised, margins ciliate, green, principal veins radiating from a bright carmine spot near the center, under side pale green; petiole thick, terete pilose: fls.  $2\frac{1}{4}$  in. diam., cinnabar-red: caps. smooth, unequal wings. Peru, 12,000 ft. B.M. 5663. F.S. 22:2326.—One of the progenitors of the tuberous race. Intro. 1867. Probably not now in cult., but a beautiful species.

10. *octopétala*, L'Her. (*B. grandiflora*, Knowl. & West). Lvs. on long, succulent downy petioles  $1\frac{1}{2}$  ft. long, cordate, deeply lobed and serrated, bright green: fls. seldom produced in cult., greenish white, in corymbs, males with 8 or 9 petals 2 in. across, females smaller and generally fewer. Intro. to Glasgow from Lima, Peru, in 1835. B.M. 3559. F.S. 20: 2056–7. A.F. 4:225 (var. *Lemoinei*). This species is of little or no horticultural value.

AA. Plant with st. (not scapes) evident and more or less upright, usually branching.

B. Lvs. narrow, lanceolate to ovate-lanceolate.

### 11. boliviensis, A. DC. Fig. 508.

Plant sparsely 508. *Begonia boliviensis* ( $\times \frac{1}{4}$ ). No. 11.

hairy: st. erect at first, but drooping and becoming slender with age, 2-3 ft. high, branching: lvs. lanceolate to ovate-lanceolate, acuminate, serrate, 3-5 in. long: fls. in drooping panicles, cinnabar-scarlet, long and fuchsia-like; males twice as long as females. Bolivia. B.M. 5657.—Intro. into England in 1864. It is a very useful basket-plant. This species has recently been crossed with some of the double and single garden forms of the tuberous race (of which this species was one of the ancestors), and has given rise to a pretty and distinct type with long pendulous sts. and drooping fls. which render them most useful as subjects for baskets. *B. Bertinii*, Hort., is closely allied, and perhaps a form of *B. boliviensis*. Fls. light scarlet, numerous and large, not so pendent. *Gt. 51*, p. 550, desc. R.H. 1894, p. 247. There is a dwarf form (var. *nana*) of this. *B. Worthiana*, Hort., said to be a seedling of *B. boliviensis*, with larger and shorter lvs. and more numerous and less pendent fls. *B. bolidavis*, Hort., is a hybrid of *B. Davisii* and *B. boliviensis*.

12. *Sutherlandii*, Hook. Slender and graceful, 1-2 ft. high, bright vinous red, from small tubers: lvs. 4-6 in. long, lanceolate, lobed and serrated, green, with red veins and margin; petioles slender, red: fls. numerous, coppery or salmon-red. Natal. B.M. 5689.—Intro. by Backhouse in 1867. Of little decorative value.

BB. *Lvs. broad-ovate to cordate-ovate.*

13. *Pearcei*, Hook. Pubescent, branching, 1 ft. high: lvs. oblique-ovate, cordate, acuminate, toothed, glabrous and velvety green above, tomentose beneath, pale red on under surface: fls. in loose, axillary panicles, large, bright yellow. Bolivia; intro. from La Paz, being sent by Mr. Pearce, collector for Messrs. Veitch. B.M. 5545.—A variable plant, both in habit, size, color of the fls. and in the degree of the venation of the strongly nerved lvs. It is the only yellow-fl. tuberous begonia in cult. It has been the chief factor in the production of the hundreds of yellow, buff and orange-colored garden forms. Intro. in 1865.

14. *Clárkei*, Hook. Stout and erect, 2 ft., puberulent, the st. purplish, fleshy: lvs. obliquely cordate-ovate, serrate: fls. in pendulous racemes, abundant,

509. *Begonia Dregei* ( $\times \frac{1}{6}$ ). No. 17.

large, bright red. Bolivia, 9,000-10,000 ft. B.M. 5663 (as *B. Veitchii*), 5675.—Resembles *B. Veitchii*. It was the seed parent of *Vesuvius* and *Emperor*, two important and useful varieties for bedding out. Probably not now in cult.

510. *Begonia tuberhybrida*. Single-flowered ( $\times \frac{1}{4}$ ). No. 21.

which are produced in quantities in the axils of the lvs. after flowering, and which will give flowering plants the following year. Stands some frost.

16. *gracilis*, HBK. (*B. bicolor*, Wats. *B. diversifolia*, R. Grah.). Smooth and shining, tall and st. erect, seldom branched, succulent: lvs. thinly scattered along sts., almost heart-shaped, slightly hairy, lobed, denticulate, ciliate: fls. on short, axillary peduncles, pink. Mex. B.M. 2966.—In axils of lvs. between stipules a cluster of bulblets is borne. These may be gathered and sown as seeds. Along with its varieties, *annulata*, *diversifolia*, *Martiana*, and others, it makes a very beautiful summer-flowering greenhouse begonia.—Intro. by P. Neill, of Cannonmills, Edinburgh, in 1829. This species should be treated in exactly the same way as the garden race of tuberous begonias as to cult. The variety *Martiana* is a large-fl. form with rose-colored fls. and frequently reaches 5 ft. in height. It is a pretty and desirable greenhouse plant, producing a succession of fls. for 2-3 months during the summer.

17. *Drégei*, Otto & Dietr. (*B. affra*, Meisn. *B. parvifolia*, Grah. *B. reniformis*, Hort.). Glabrous: sts. succulent, annual, 1-3 ft. high: from a rootstalk a fleshy irregular tuber: lvs. thin, small, oblique-ovate, green, deeply serrated, reddish on the under side: fls. white, small, profuse. Cape of Good Hope. B.M. 3720.—Received at Botanic Gardens, Edinburgh in 1836 from Berlin. A useful free-flowering greenhouse plant.

18. *weltoniensis*, Hort. (*B. Sutherlandii*  $\times$  *B. Drégei*). St. reddish, 1-3 ft. high: lvs. light green, smooth, ovate-acuminate, lobed, dentate,  $1\frac{1}{2}$ -2 in. across; petiole red,  $1-1\frac{1}{2}$  in. long: fls. pink, profuse, on short peduncles.—Frequently met with in cottagers' windows in England; of very easy cult. Intro. by Major Clark, of Welton Park, England. Var. *alba*, Hort., has white fls.

19. *fulgens*, Lemoine. Stout: st. short: lvs. large-reniform to cordate-ovate, more or less oblique, irregularly sinuate-toothed, sparsely hairy above and beneath, dull dark green above and reddish on the under side.

15. *Evansiana*, Andr. (*B. discolor*, R. Br. *B. grandis*, Dry.) Smooth: st. deciduous, branching, 2 ft. high: lvs. ovate-acute, subcordate, lobed, margins denticulate, green above, under side and petioles red, peduncles branching, axillary: fls. numerous, flesh-colored, large. Java, China, Japan. B.M. 1473.—A handsome and almost hardy species. Intro. in 1804 to Kew. Little cult. now. It makes a pretty and free-flowering plant for the cool greenhouse in summer. Readily prop. by bulblets,

fls. large (2 in. across) in many long-peduncled clusters, bright rich rose-red, fragrant. Bolivia.—A handsome plant, published by Lemoine in catalogue of 1893.

BBB. *Lvs. orbicular.*

20. *Baumannii*, Lemoine. Lódse-hairy or nearly glabrous, the sts. often very short and the plant appearing acaulescent, but becoming 1-1½ ft. high: lvs. large, orbicular, with short, thick petioles: peduncles 18 in. high, bearing panicles of 4-6 fls., which are rose-red, 4-petaled, from 3-4 in. across, and fragrant as roses. Bolivia, 8,000-9,000 ft. B.M. 7540. Gt. 40:1348; 42, p. 25. A.F. 7:561. G.F. 5:77.—It is described as plentiful in the moist valleys of the Cordilleras, where it is eaten by cattle. Distributed by Lemoine in 1890. Tubers as large as ostrich eggs. Habit of *B. socotrana*.

BBBB. *Lvs. various, mostly broad-ovate at base, acuminale, oblique.*

21. *tuberhýbrida*, Voss (*B. tuberósa*, Hort.). Figs. 510, 511, 512. The garden race of tuberous begonias, combined of many species and derived from many sources, very variable and yet for the most part agreeing in general lf. form. There are many named garden varieties.

OTHER TUBEROUS-ROOTED SPECIES.

22. *cinnabarina*, Hook. Puberulent: sts. short, green, zigzag, slightly downy: lvs. on short petioles, obliquely ovate, lobed and serrated: peduncles 9-12 in. long, red; fls. cinnabar-red, 2 in. across. Bolivia. B.M. 4483. P.M. 16:225.—Intro. 1849; not in cult.

23. *crinita*, Oliver. Slender, sparsely hairy: sts. red, hairy, 1 ft. high: lvs. ovate-cordate, irregularly toothed, tinged with red on the under side: peduncles erect, red, producing 3 pale rose-colored fls. Bolivia. B.M. 5897.—Intro. by Veitch in 1866.

24. *cyclophýlla*, Hook. Slightly hairy, slender, stemless: lf. solitary, orbicular, 6 in. across, green, with fimbriated margin: peduncles erect, 6 in. long; fls. rose-colored, with the fragrance of roses. China. B.M. 6926.—Intro. to Kew in 1885.

25. *geraniifolia*, Hook. Glabrous: st. 1 ft. high, erect, greenish: lvs. cordate, lobed, incised and serrated, green, margins red: fls. 2 or 3 on terminal peduncles, outer petals orbicular, red; the two inner obovate, white. Lima. B.M. 3387.—Intro. 1833.

26. *geranioides*, Hook. Small, 10-14 in., stemless, rootstock fleshy: lvs. radical, reniform, 6 in. across, lobed and toothed, green, hairy, petioles 8 in. long; peduncles erect, 6-12 in. long, reddish, hairy, bearing a lax panicle of fls., each 1¼ in. across, pure white, with a button-like cluster of yellow anthers. Natal. B.M. 5583.—Planted in a border in a sunny greenhouse, this is a fine begonia,

512. *Begonia tuberhybrida*.  
Double-flowered form. No. 21.

flowering profusely during Oct. and Nov. Intro. to Kew in 1866. Probably not now in cult. Allied to *B. Dregei*.

27. *natalénsis*, Hook. Glabrous: sts. fleshy, 1-2 ft. high: lvs. obliquely cordate, lobed, sinuate, 2-3 in. long, green, sometimes mottled with gray, veins reddish: fls. yellowish white, tinged with rose, 1 in. across. Natal. B.M. 4841.—Intro. to Kew in 1854.

28. *polypétala*, A. DC. St. short, fleshy: lvs. ovate-cordate, toothed, hairy, with raised veins, 10x8 in.: fls. with 9 or 10 ovate-oblong petals an inch long, red; ovary hairy, with 1 long wing. Peru. Gn. 14, p. 531.—Intro. by Froebel in 1878.

29. *rubricaùlis*, Hook. Pubescent, stemless, scapes red: lvs. 4-6 in. long, ovate, wavy, ciliate along the margins, deep green: fls. large, males 1¼ in. across, 5-petaled; females smaller, 6-petaled, reddish. Country unknown. B.M. 4131.—Intro. to Birmingham Botanic Garden in or about 1844.

30. *ténera*, Dry. (*B. Thwaitesii*, Hook.). Pubescent, stemless: lvs. radical, cordate, 5 in. long, coppery green, mixed with purple and blotched with gray, under surface very red: fls. white, tinged pink. Ceylon. B.M. 4692.—Chiefly interesting as a variegated plant. Intro. to Kew about 1852.

III. SPECIES RHIZOMATOUS: the rhizomes mostly shaggy and lying on top the ground or very nearly so (Fig. 516); plant making no proper upright stem or trunk. Nos. 31-59.

A. Plant creeping, trailing, or climbing.

31. *glaucophýlla*, Hook. (*B. glaucophýlla splendens*, Hort. *B. glaucophýlla scándens*, Hort. *B. Comte de Limminghe*, Hort. *B. Limminghei*, Hort.). Glabrous: sts. long, drooping or creeping, lending themselves to training on rafters: lvs. ovate, wavy, 3 in. long, glaucous green, reddish and variegated in bud, purple beneath and white-spotted above, the margin cartilaginous: fls. brick-red, males 1 in. across, with petals, females of equal petals. Brazil. B.M. 7219. Gn. 59, p. 336.—A good basket plant, flowering freely all winter. Excellent for a permanent position in a greenhouse; reaches 6-8 ft. or more high.

32. *scándens*, Swartz (*B. lucida*, Otto & Dietr. *B. elliptica*, HBK.). Glabrous: sts. climbing or trailing clinging by means of short aërial roots: lvs. ovate or broader, acuminate, notched at base, dentate, glossy green, 4 in. long: fls. small, white, hanging in ball-like clusters. W. Indies and S.—An excellent basket or climbing plant.

511. *Begonia tuberhybrida*. Double-flowered. No. 21.

AA. *Plant upright, often diffuse.*

B. *The picture-lvd. set: plants low and tending to be compact, the mature lvs. usually hanging nearly vertical, often variously colored and marked.*

C *Lvs. oblique, lobed at the base, not pellate (or only slightly so).*

33. *Réx*, Putz. Fig. 513. Very hairy: st. a short, fleshy rhizome, from which spring the long-stalked large ovate wavy lvs., which are hairy and colored a rich metallic green, with a zone of silvery gray: peduncles erect; fls. large, rose-tinted; males 2 in. across, with 4 unequal petals; females smaller, with 5 nearly equal

513. *Begonia Rex*, in its original form. No. 33.

petals; ovary 3-angled, with 2 short and 1 long wing. Assam. F.S. 12:1255-1258. B.M. 5101.—This noble species is the principal parent in the production of the numerous ornamental-foliaged begonias. It has been crossed with a few species in the first place, and then hybrid seedlings have been raised again and again from the progeny. Fig. 513 is a copy of a part of the original figure in *Flore des Serres* (1857), and is given here for the purpose of showing what this species was like when first known to horticulturists. There are very many named forms, but most of the listed kinds tend soon to pass out. One of them that has persisted, because of the odd quirk to the lf. is *Countess Louise Erdoedy* (*B. Alexander von Humboldt* × *B. argentea-cupreata*). Fig. 514. Lvs. obliquely cordate, ovate-acute, the smaller of the 2 lobes twisted in a spiral manner, with as many as 4 coils; upper surface silvery, with veins deep green; under surface reddish, pilose. I.H. 31:516. C.C. II. 22:205. Intro. by F. Nemeček, gardener to Count Erdödy, a Hungarian nobleman, in 1884.—Other *Rex* varieties of unknown or uncertain origin: *Louise Closson*. Lvs. ovate-acuminate, lobed, veins deep purple, surface blotched with deep purple bronze, metallic luster very bright. *Lucy Closson* is very similar, but more vigorous, with the blotches more numerous and better distributed. *Marquis de Peralta*. Lvs. small, margins hairy, numerous silvery spots on surface. Compact, dense grower. *Duchesse de Brabant*. Lvs. large, purple, margins and surface hairy, otherwise like *B. Rex*. *Louise Chretien*. Lvs. green, with a zone of glossy silver towards the center, covered with very small white spots. *Count Erdoedy*. Silver-white, green-striped along the veins, hairy; lobes twisted into a spiral, hairy.

34. *xanthina*, Hook. Similar to *B. Rex*: lvs. large, fleshy, cordate-ovate, acuminate, sinuate-ciliated, dark glossy green above, purplish beneath: fls. large, almost golden yellow, tinged on the back with red: caps. with one large wing. India. B.M. 4683. Var. *pictifolia*, Hook. Lvs. with rows and spots of silvery white: fls. yellowish white. B.M. 5102. Var. *Lázulii*, Hook. Lvs.

not spotted, tinted with bluish purple. B.M. 5107. This species is probably not now in cult.

35. *Griffithii*, Hook. (*B. picta*, Hort.). St.-lvs. and habit as in *B. Rex*: lvs. olive-green, with a broad zone of gray inside a purple margin, tinged with red on the under side, the basal lobes overlapping: fls. large, fleshy, pink; ovary curiously crinkled along the angles. Assam. B.M. 4984.—Intro. by Henderson, England, in 1856. Probably not now in cult.

36. *Rajah*, Ridley. Fig. 515. Lvs. from the rootstock, angular-orbicular, papery, the petioles and under veins setose, upper surface smooth and richly mottled from the green ribs and the brown or brown-red intermediate spaces, the margins serrate and setose: fls. small, pink, on hispid peduncles that stand about as high as the lvs. Malaya. G.C. III. 16:213.—A distinct and beautiful hothouse species, deserving of popularity. Said erroneously to be a garden hybrid.

37. *Augústinei*, Hemsl. A dwarf, compact species, allied to *B. Rex* but devoid of color in the lvs. as in that species: sts. branching freely, short-jointed: lvs. erect or spreading, elliptic or ovate, 3-6 in. long, reddish green above and below, covered on both sides with red hairs; petiole red, terete, provided with dense white hispid hairs: whole plant presenting a mixture of white or red hairs: infl. erect, few-flid.; fls. pink. China.—Differs from *B. xanthina* in its rough rugose hairy lvs. and rose-pink fls.

38. *dædalea*, Lem. (*B. strigillosa*, Dietr.). Hairy, *Rex*-like: st. a short, thick rootstock: lvs. large, green, ovate-acuminate, cordate, margins slightly serrate and beset with long reddish hairs, surface covered with a peculiar network of russet-brown: peduncles spotted and slightly hairy; fls. white, tinged with pink. Mex. I.H. 8:269.—A handsome foliage plant, not very widely known.

39. *speculata*, Hort. Probably a hybrid: st. a short, thick rhizome: lvs. broadly ovate, acuminate, cordate, lobed half way down the blade, on long, hairy petioles, dull green, rough, speckled with gray, hairy, reddish on the under side, veins very prominent, light green: fls. on long, hairy peduncles, pink-white, males and females both with 2 petals: caps. green, with small red

514. *Begonia Countess Louise Erdoedy* (× 1/2). No. 33.

spots.—Origin uncertain, although apparently common in cult. in this country. A hardy and useful begonia for conservatory and window-garden.

40. *decora*, Stapf. A small species of compact habit, allied to *B. Rex*: rhizome short, reddish green: lvs. 3-4 in. long, ovate, rich reddish brown with prominent yellow-green veins: whole plant covered with thick-set papillæ and short hairs: fls. pink, comparatively large for so small a plant. Perak.—This plant thrives best in a stove. It is readily crossed with many other species, notably with *B. Rex*, and the offspring are amongst the finest ornamental foliage plants.

41. *imperiâlis*, Lem. Very hairy, low: st. short, herbaceous, green: lvs. 4-6 in. wide, brownish green, with irregular bands of bright green along the nerves, making a striking contrast: fls. insignificant, white. Mex. I.H. 8:274. Var. *maculâta*, Hort., has brown lvs. with green blotches. Var. *smarâgdina*, Hort., has wholly bright green lvs. I.H. 7:262.—These plants require a hothouse treatment in winter.

cc. *Lvs. markedly peltate.*

42. *môdica*, Stapf. A spreading, dwarf plant with sts. green, slender: lvs. peltate, orbicular or broadly ovate, 2-4 in. long, pale green in color, margins pink, undulate, margins and veins ciliate; petioles greenish red, hairy, 3-5 in. long: infl. few-flid., males small, 2-petaled, orange-yellow, with red blotch at base of petals, females same as males in color; ovary 4-celled, ½ in. long, winged, hairy. W. Trop. Afr. B.M. 8258.—A recent species, requiring stove conditions.

43. *Géntilii*, De Wild. A near ally of *B. modica*: sts. creeping, red hairy: lvs. peltate, erect, ovate, acute, margins finely serrate, slightly reflexed, green suffused with light red, young lvs. red; petiole terete, red, hairy, 6-12 in. long; blades 3-4 in. long: infl. few-flid.; fls. orange-yellow suffused with red; ovary 4-celled, winged. Congo.

44. *Binôtti*, Hort. Plant rough-hairy like *B. Rex*: lvs. elliptic-orbicular, markedly peltate, green above and red-hairy beneath, blistered or bullate.—Very recently offered, and yet little known.

45. *goegoënsis*, N. E. Br. FIRE KING. Compact but large plant: st. a short, thick, greenish red rootstock: lvs. handsome, erect, peltate, ovate-orbicular, 6-9 in. long, surface blistered or puckered green, with dark bronzy blotches, prominently veined, dull red on the under side: fls. small, rose-pink, in a lax cluster 6 in. high. Goego, Sumatra.—A distinct and ornamental-ld. plant, requiring stove conditions; deserves the attention of amateurs.

BB. *The essentially plain-lvd. rhizomatous kinds, although some of them are grown almost wholly for the foliage. (Some of this group are bold and striking.)*

c. *Lvs. prominently lobed, or parted or even divided.*

46. *ricinifôlia*, Hort. (*B. heracleifôlia* × *B. peponifôlia*). St. a short, thick rootstock: lvs. large, bronzy

515. *Begonia Rajah* (× ½). No. 36.

green, lobed, resembling castor-oil plant: fls. numerous, on long, erect peduncles, rose-pink.—A useful free-flowering plant for the greenhouse, producing its fls. in winter and early spring. Var. *gigantëa odorâta*, Hort., is a double hybrid (*B. ricinifôlia* and *B. fulgens* × *B. Scharffiâna*) of German origin. Lvs. large, round-cor-

date, the lobes extending one-third or less deep and notched: fls. on long scapes, standing above the lvs., delicate rose-color and with tea-rose odor. Gt. 54, p. 42.

47. *heracleifôlia*, Cham. & Schlecht. (*B. jatrophæfôlia*, Hort.). Hairy: st. a short, thick rhizome: lvs. 6-12 in. across, with 5-9 deep and narrow notched and toothed

516. *Begonia magnifica* (× ½). No. 59.

lobes, rich green: peduncles 2-4 ft., long, straight: fls. white or rose-tinted, small, with 2 prominent rounded parts. Mex. B.M. 3444. B.R. 1668. J.H. III. 56:309. Var. *nigricans*, Hook., has the margins of the lvs. bordered with dark (almost black) green. B.M. 4983. Var. *longipila*, Hort., has long, fleshy hairs on the lf-stalks and peduncles. *B. Sûnderbruchii*, Hort., is an American form of this var.: lvs. bronze-green, silver bands along the nerves, purple underneath. Var. *punctâta*, Hort., has green lvs., reddish near the margin: fls. rose-colored, with deep red spots on the outside.

48. *rubëlla*, Hamil. Smooth: st. a short, thick rhizome: lvs. handsome, large, cordate, acuminate, deeply lobed, spotted with irregularly shaped dark brown marks: fls. pale pink, on long peduncles, decorative. Nepal.

49. *Verschaffeltiâna*, Regel (*B. Verschaffeltii*, Hort. *B. manicâta* × *B. carolinæfôlia*). Hairy: st. a thick rhizome: lvs. large, ovate, acuminate, lobed: fls. rose-colored, pendent on long peduncles. I.H. 2:68.—Tall, coarse and unsightly as an old specimen, but when well grown from year to year from cuttings makes an excellent plant and produces quantities of its small rose-colored fls. in early spring, which last for several months and have a considerable decorative value.

50. *heracleicôtyle*, Veitch (*B. heracleifôlia* × *B. hydrocotylifôlia*). A small, essentially smooth plant, with lvs. close to the rhizomes: lvs. thick, obliquely cordate-ovate, many-lobed and toothed, margins slightly ciliate, shining metallic green above and reddish beneath: fls. pink, small, freely produced on about 8 free-branching peduncles in early spring. Veitch, 1895.—A useful and decorative greenhouse plant.

cc. *Lvs. lanceolate to ovate or cordate-ovate to orbicular, not deeply lobed, often entire, and sometimes peltate.*

d. *Foliage small, the lvs. less than 2 in. wide.*

51. *hydrocotylifôlia*, Otto. Whole plant hairy: st. succulent, creeping: lvs. rotundate-cordate, repand bu-

entire, small, on short petioles and therefore clustered near the ground: peduncles 1-1½ ft. high, pilose; fls. dipetalous, rose-colored, small and numerous, showy. Mex. B.M. 3968.

DD. *Foliage of usual or large size.*

E. *The lvs. peltate.*

52. *Féastii*, Hort. (*B. manicata* × *B. hydrocotylifolia*). Shaggy-hairy on petioles and lf.-edges: st. a short, thick rootstock: lvs. suborbicular, thick, red beneath,

517. *Begonia semperflorens*. A recently struck cutting. To show the precocity of bloom. No. 60.

entire with long white hairs on margins; petioles short, irregularly marked: fls. light pink, on long peduncles. A.G. 23:335.—Intro. by John Feast, of Baltimore, before 1880. A common pot and house plant. *B. Bunchii*, Hort., is a form with edges of lvs. crested and frilled. Originated with Lloyd C. Bunch, Fredonia, Kan.

53. *nelumbiifolia*, Cham. & Schlecht. Hairy: st. a short, thick rhizome: lvs. large, 12-18 in. long, 8-12 in. wide, peltate, hairy on the under side, on long upstanding petioles: fls. many and small, white or rose-colored, in a dense erect much-branched cluster. Mex.—The foliage is bold and handsome, and distinct in general effect from any other cult. species.

54. *conchæfolia*, A. Dietr. Lvs. nearly peltate or semi-peltate, thick, cordate-ovate and the basal lobes or ears overlapping, margins entire or repand, becoming smooth above, shining green above and reddish beneath: fls. pink. Cent. Amer.

55. *Lubbersii*, E. Morr. Semi-shrubby, the short rhizome occasionally ascending and becoming gouty at the base: lvs. large, peltate, obliquely lanceolate, entire, green with many silvery blotches above, claret-colored beneath: fls. white, on long peduncles. Brazil. G.C. III. 3:301. R.H. 1888, p. 225.—Named in compliment to M. Lubbers, curator Brussels Bot. Gard. Has spots like *B. maculata*.—Of little horticultural value.

56. *álbo-coccinea*, Hook. (*B. Grahmiana*, Wight). Smooth and shining: rootstock creeping: lvs. peltate, ovate, leathery, 6 in. long: peduncles 1 ft. long, coral-red, springing from the crown; male fls. 1 in. across, with 4 petals; female fls. also of 4 petals, white above, coral-red beneath. Flowers in winter. India. B.R. 32:39. B.M. 4172.—A beautiful species, apparently little cult. now.

EE. *The lvs. not peltate.*

57. *manicata*, Cels. Essentially smooth except the hairy lf.-edges, short-stemmed, succulent: lvs. ovate, obliquely cordate, thick, fleshy, smooth, shiny green, 6-8 in. long; petioles covered with fleshy scale-like hairs: peduncles a foot or more long, bearing loose panicles of pink dipetalous fls. Mex. Var. *aureo-maculata*, Hort., has large blotches of yellowish white on the lvs. F.E. 8:1159. F.R. 2:435. A.G. 23:337.—Flowers profusely in spring, having a light elegant and feathery effect supported on long erect and free-branching peduncles. Var. *crispa*, Hort., has foliage with crispate margins; there is also a yellow-spotted form of it.

58. *leprøsa*, Hance. A dwarf, compact species, with short, free-branching rhizomes and erect, ovate, pale green lvs. with biserrate margins and reaching to a height of 6-9 in.: infl. few-fl.; fls. large for so small a plant, rose-pink, male with 4 petals and female with 6 petals: partially deciduous during the winter months. China.—Thrives best in a greenhouse.

59. *magnifica*, Lind. Fig. 516. Sub-frutescent, smooth and shining, the sts. creeping: lvs. large and bold, sometimes rising 2 ft., obliquely ovate-cordate, entire or obscurely lobed, serrate, slightly peltate, bright green, the margins ciliate: fls. long and fuchsia-like, numerous, the sts., bracts, fls. and hairs of the clusters all scarlet-red, showy. Colombia. R.H. 1870: 270.—One of the best of the rhizomatous begonias. Lf.-blades often 2 ft. across.

#### IV. SPECIES FIBROUS-ROOTED (*rootstock, if any, small*). Nos. 60-119.

A. *The small succulent herbaceous kinds, never becoming very tall or woody.*

60. *semperflorens*, Link. & Otto (*B. Sellowii*, Klotzsch). Fig. 517. Erect, smooth plants with st. herbaceous, green or reddish, 6-18 in. high: lvs. ovate, rotundate, obtuse at the base, toothed and ciliate along the margin, pale glossy green, tinged with red on the midrib and petiole: peduncles axillary, few-fl.; fls. white or rose-colored; males with 4 petals, females with 5 petals: caps. green, wings tinged with red. Brazil. L.B.C. 15:1439. R.H. 1897, p. 46. B.M. 2920.

—This is an exceedingly variable species. An endless number of garden forms has been produced from it. A very popular bedding begonia, and a persistent bloomer. Var. *Vernon* (*atropurpurea compacta*, Gt. 44, p. 570) is one of the best forms. *Triomphe de Lorraine* (Fig. 518) is one of the good bedding kinds. Fls. cherry-red, the stamens golden yellow. *Gloire de Châtelaine* is a form of dwarf habit and deep rose fls.; one of the best in England for bedding and pots, and a continuous bloomer.

61. Var. *gigantæarøsea* (*B. semperflorens* × *B. Lyncheana*). Very distinct: rootstock woody: sts. succulent, about 3 ft. high: lvs. on short petioles, ovate or reniform, obtuse, toothed at

518. *Begonia, Triomphe de Lorraine* (×½). No. 60.

XIV. Foliage begonias well grown in banks, with ferns and similar plants.

the margins, about 7 in. across, bright green, with a red spot at base of sinus: peduncles axillary stout, 4-8 in. long, bearing large panicles of large rosy red fls., of which the males have 2 ovate petals, the females 2-4 smaller petals. A.F. 13:586. A.G. 16:41.—One of the best begonias for winter decoration in the cool greenhouse. Intro. by Lemoine in 1888.

62. *Carrierei*, Hort. (*B. semperflorens* × *B. Schmidtii*. *B. Bruantii*, Hort. *B. Smilhii*, Hort.). DEWDROP. Compact, about 1 ft. high: lvs. like *B. semperflorens*: fls. nearly as large as in *B. semperflorens*, abundant, pure white. G. 6:557. J.H. III. 53:249.—Excellent bedding begonia; also a good late winter bloomer. Intro. by Bruant in 1883.

63. *Érfordii*, Hort. (*B. Schmidtii* × *B. semperflorens* Vernon). Very dwarf and bushy, 1½ ft. high: fls. abundant, rose-carmine.—Excellent for bedding. Intro. by Haage & Schmidt in 1894.

64. *Lyncheana*, Hook. (*B. Roëzii*, Hort., not Regel). Glabrous: rootstock stout, somewhat tuberous: st. erect, tall, succulent, smooth: lvs. green, smooth, ovate-cordate: sinus red: fls. in axillary, drooping cymes, deep reddish crimson. Mex. B.M. 6758.—Very like *B. semperflorens gigantea rosea*, but not so strong a grower. Perhaps not now in cult.

65. *Luciænæ*, Hort. (*B. Lyncheana* × *B. Bruantii*). Fls. large, in the axils of the lvs., rose.—Intro. by Bruant in 1889.

66. *Corbeille de Feu* (*B. semperflorens* × *B. fuchsioides*). Fig. 519. Intermediate in habit between its parents: fls. bright coral-red, produced in quantity nearly all the year round.—The plant branches freely from the base and makes an excellent bedding plant; the fls. are rich-colored and withstand the sun well. Intro. by Lemoine, 1891.

519. *Begonia Corbeille de Feu* ("Basket of Fire") (×½). No. 66.

AA. The kinds becoming woody or shrubby, mostly tall and much branched.

B. Plants slender, upright, small-leaved.

C. Fls. pink or red.

67. *fuchsioides*, Hook. Fig. 520. Smooth: rootstock woody, not prominent: sts. slender and erect, 2-3 ft., succulent: lvs. many and small, ovate, 1½ in. long, tinged with red when young: fls. drooping like a fuchsia, rich scarlet, males with 4 petals, females with 5 petals. Mex.—Requires the conditions of a warm airy greenhouse. If kept in a moist close atmosphere it is apt to damp off badly, and if kept too warm it makes a lot of growth and produces very few fls. It rapidly forms a large specimen if kept growing, and is a most attractive plant for greenhouse decoration during winter and spring months. B.M. 4281. Var. *miniata*, Lind. (*B. cinnabarina*, Hort.), differs only in having flesh-colored fls. and smaller lvs. R.H. 1855:221. F.S. 8:787.

68. *Ingramii*, Hort. (*B. nitida* × *B. fuchsioides*). Fig. 521. Combines the characters of the two species: very free-flowering and makes a most desirable bedding plant, and also blooms well in winter: fls. rose, large: foliage tinted with red when exposed to the sun. The

horizontal blooming side branches are characteristic of this plant as a greenhouse subject.—Intro. by Ingram in 1849.

69. *Digswelliana*, Hort. (*B. Sandersonii*, Hort.) A useful hybrid probably between *B. fuchsioides* and one of the numerous varieties of *B. semperflorens*: sts. erect or nearly so, green suffused with red: lvs. elliptic, serrate, 2-4 in. long, dark rich green in color: infl. medium in length and size; fls. rosy scarlet, pendulous.—A useful bedding plant or may be used for a cool greenhouse.

70. *incarnata*, Link & Otto (*B. aucubæfolia*, Hort. *B. insignis*, Grah.). Smooth: st. erect, sub-herbaceous, 2-3 ft. high: lvs. very unequally cordate, ovate-lanceolate, toothed: fls. rose-colored, abundant, males 1½ in. across, with 2 ovate and 2 narrow petals; females smaller, with 5 equal petals. B.M. 2900. A.G. 16:97. A.F. 12:724-5; 13:588; 17:857. R.H. 1870, p. 266; 1875:151. Var. *grandiflora*, Hort., is a much improved variety, very useful for cut-fls. or decoration in winter.

71. *ascotiensis*, Weber. Of hybrid origin, probably obtained from *B. fuchsioides* and one of the forms of *B. semperflorens*: lvs. ovate, 2 in. long, smooth, brown, margin green, dentate: fls. on peduncles 4 in. long, bright red.—An excellent bedding begonia.

CC. Fls. white, or tinted white.

72. *foliösa*, HBK. Small, smooth, shrubby: sts. herbaceous, slender, branching: lvs. very many, frond-like, very small, somewhat 3-lobed, glossy green, distichous: fls. white, tinged with rose. Blooms early summer. Colombia.—An elegant little basket and ornamental plant.

73. *knowsleyana*, Hort. Much like *B. incarnata*, but lf. smaller, entire or nearly so: fls. nearly white. Named for Knowsley, seat of the Earl of Derby. Origin not known; probably a seedling of *B. acuminata*. A good winter bloomer, particularly in 6-in. pots. J.H. III. 49, p. 177.

521. *Begonia Ingramii* (×½). No. 68.

74. *acuminata*, Dry. Slender, 3-4 ft.: sts. nearly or quite smooth: lvs. 2-3 in. long, oblique-ovate, tapering to the point, toothed and serrate, the margin and veins underneath hairy: fls. white, 3-5 on a peduncle, nearly 1 in. across, spring and summer. Jamaica.—A

520. *Begonia fuchsioides* (×¾). No. 67.

useful plant for growing in baskets, thriving and flowering freely in a sunny position in a cool airy greenhouse. Intro. to Kew in 1790. B.M. 4025. B.R. 364.

75. *álbo-pícta*, Hort. Shrubby, compact growth, freely branched: lvs. elliptical, lanceolate, covered with

522. *Begonia Scharfiana*. No. 89.

numerous small silvery white spots: fls. greenish white. males with 2 broad and 2 narrow petals, females of 5 subequal petals. Brazil.—An elegant foliage plant, especially in the young state. Intro. by Bull in 1885.

BB. *Plants low-growing, diffuse.*

76. *Schmidtiana*, Regel (*B. Schmidtii*, Hort.). Herbaceous or half-shrubby, slender-branched, 1 ft. or less in height, the branches red-tinged: lvs. lobed, toothed, hairy, about 2 in. long, reddish beneath: fls. white, tinted with rose. Brazil. R.H. 1883, pp. 56-7. Gn. 17, pp. 268-9.—A very useful plant for summer bedding. Named for Mr. Schmidt, of the firm of Haage & Schmidt, Erfurt. Var. *rosea*, Hort., has rose-red fls.

BBB. *Plants stiff, succulent, white-scurfy.*

77. *peltata*, Hassk. (*B. Hasskarlii*, Zoll.). Upright: st. perennial: lvs. peltate, ovate-acuminate, very thick and succulent, covered with a whitish tomentum, 6-9 in. long: fls. small, white, on long peduncles. Brazil.—It is the only begonia in cult. with thick, felted, peltate, silvery lvs.

78. *venosa*, Skan. A tall, stout, erect species with white-frosted very fleshy foliage, and marked by very large inflated conspicuously veined stipules: lvs. reniform or ear-shaped, repand-entire, joined at the middle (not peltate) with the thick flattened petiole: fls. many, white, crowded on a reddish peduncle. Brazil. B.M. 7657.—Very distinct, and a striking plant when well grown. Requires a warm sunny position in the greenhouse, and to be kept rather on the dry side at the roots during winter.

BBBB. *Plants mostly tall and erect, distinctly shrubby.*

c. *Lvs. compound or nearly so.*

79. *luxurians*, Scheidw. Sts. and lf.-stalks hairy, the lf.-stalks reddish: pointed membranous stipules at the younger nodes: lvs. peltately compound, the 7-17 lfts. lanceolate (3-6 in. long and 1 in. broad), serrate, under surface glabrous and green, upper surface with stiff short hairs and red: fls. small, cream-color, in a

compound long-stalked cluster. S. Amer. G.C. III. 51:28.—Thrives in an intermediate temp.

80. *Hemsleyana*, Hook. Slightly hairy: habit dense, free-branching: sts. erect, red, hairy: lvs. digitate 6-12-parted, the parts or lfts. lanceolate or elliptic, slightly curved, serrate undulate, rich shining green above, dull greenish red beneath: petiole long, red: sts. and petioles covered with soft-tomentose hairs: infl. slender, few-fl.; fls. pink, large, 1-1½ in. diam. Yunnan, S. China. B.M. 7685.—One of the hardest species.

81. *platanifolia*, Hort. (Schott?). St. shrubby, smooth, 5-6 ft. high, erect, robust, smooth, green, joints annulated: lvs. 8-10 in. across, reniform, lobed half way down, hispid on both sides, dark green, lobes acute, toothed, ciliated: fls. in axillary dichotomous cymes, large, white, tinted rose. Brazil. B.M. 3591.—*B. gunneræfolia*, Lind. (*B. Washingtoniana*, Hort.), is very similar to this, but its lvs. are not so deeply lobed and the fls. are very insignificant. I.H. 22:212. Runs into many forms. See *B. Faureana* in supplementary list, p. 484.

82. *digitata*, Raddi (*B. palmata*, Hort.). St. short, gouty: lvs. palmate, 10-12-parted, somewhat pubescent, green above, brownish beneath: fls. white, in dense clusters. Brazil.—A species of little decorative value.

83. *carolinæfolia*, Regel. St. erect, thick, fleshy: lvs. palmately divided into 6-8 long ovate segms.: fls. small, pink, on long peduncles. Mex. Gt. 1:258.—Named for its lvs. resembling those of the *Carolinea* (*Pachira*). The lfts. are ovate, rather than narrow as in most begonias with divided or compound lvs., and in this regard peculiar.

84. *diadema*, Lind. Sts. short and fleshy, 2 ft. high: lvs. many, maple-like, deeply parted, bright green blotched with white, dentate: fls. insignificant, pink. Borneo. I.H. 29:446.—Attractive for its conspicuously marked foliage.

cc. *Lvs. not compound.*

d. *Whole plant hairy.*

E. *Foliage light green, and plant pubescent.*

85. *vitifolia*, Schott, not Lindl. (*B. grandis*, Otto. *B. reniformis*, Hook.).

Tall, strong species, 3-4 ft. high: lvs. large and grape-like (*Vitis vinifera*), orbicular or reniform, lobed and serrate, soft-pubescent, green above and rusty veined beneath, the petiole flat or canaliculate on top: fls. small, white, slightly downy, winter. Brazil. B.M. 3225.

86. *Engleri*, Gilg. (*B. Engleri*, Hort.). Striking species with mostly a single st.: conspicuously red-strigose-hairy and scaly, becoming 5 ft. tall: lvs. large and showy, thin,

oblique and ovate-oblong, deeply and evenly serrate, hairy, red-ribbed: fls. on long pendulous peduncles, numerous, pink. E. Trop. Afr.—Distinct, and worthy of attention on account of its handsome hairy lvs.

523. *Begonia Haageana*. Showing a very small cluster ( $\times \frac{1}{2}$ ). No. 91.

EE. *Foliage colored above or beneath, or both.*

F. *Fls. white.*

87. *echinosépala*, Regel. St. green, succulent, erect and branching freely: lvs. obliquely oblong, finely serrate, rather small: fls. on axillary peduncles, white, with curiously papillose sepals. Brazil.—A useful species for warm greenhouse, of very easy cult. and very free-flowering. One of the best for decoration.

524. *Begonia cathayana* ( $\times \frac{1}{2}$ ) No. 95.

88. *erythrophýlla*, Neum. Soft-hairy, the st. fleshy, strong: lvs. thick, reniform, long-stalked, dark green and lustrous above and red beneath, almost entire, strigillose: fls. small, white.—Probably of garden origin.

89. *Scharffiàna*, Regel. Fig. 522. A robust herbaceous perennial, 1–3 ft. high: lvs. large, thick, fleshy, hairy, olive-green above, crimson below: stipules very large and prominent: fls. waxy white with red hairs on under surface of petals, large. Brazil. Gt. 1888, p. 661.—This begonia requires warmth and care to succeed well. When well grown, it is an excellent bracket-plant.

90. *Duchártrei*, Hort. (*B. echinosépala*  $\times$  *B. Scharffiàna*). St. 2–3 ft. high, branched profusely, hairy, purple: lvs. ovate-lanceolate, acuminate, green above, hairy, red below: fls. large, waxy white, a few red hairs on the under surface of petals. R.H. 1892, p. 29.—Intro. by Bruant in 1892.

FF. *Fls. colored.*

91. *Haageàna*, Wats. (*B. Scharffi*, Hook.). Fig. 523. Tall-shrubby, whole plant hairy: lvs. ovate-cordate, acuminate, wavy, red-nerved above: fls. rose-pink, with a cyme 8–12 in. diam., males with 2 round and 2 narrow petals, females with 5 equal petals. Brazil. G.C. III. 16:633. B.M. 7028, (as *B. Scharffi*).—One of the most beautiful plants of the genus, and now one of the best known of the big tall red-hairy begonias; the hanging trusses of fls. (imperfectly represented in Fig. 523) are very conspicuous. Named for one of the firm of Haage & Schmidt. *B. Credneri*, Hort. (*B. Scharffiàna*  $\times$  *B. metálica*). Intro. by Haage & Schmidt, 1890. There is another plant named *B. Credneri*, which was raised by Lemoine in 1891 from the same parents. Bruant also used these two parents in 1891, and called his plant *B. pictaviensis*. All three plants can be distinguished from *B. Haageana* only by their smaller fls. and the peduncles standing erect and not gracefully bending over, as in *B. Haageana*.

92. *Alléryi*, Hort. (*B. metálica*  $\times$  *B. gigantèa*). Of the *B. Haageana* type: hairy, lvs. bronzy, red-veined beneath, toothed: plant becoming very tall (even 4–6 ft. in a single year), producing many large pendulous clusters of rose-colored fls.—A very fine warm greenhouse or stove variety, free-flowering, of easy cult. Shown in 1905 before Société National d'Horticulture de France by M. Allery Aubert of Tours.

93. *metálica*, G. Smith. Hairy: sts. perennial, succulent, 4 ft. high, branched: lvs. obliquely cordate, lobed and serrated, 3–6 in. long, upper surface green, shaded with a dark metallic color: fls. blush-white, under side of petals clothed with red bristly hairs. There are a number of varieties, e. g., var *variegata*, var. *velútina*, var. *cýprea*, but they do not differ much from the original. Bahia. R.H. 1844:218 (as *B. velútina*). G.C. II. 5:397.—A very attractive plant.

94. *Margaritæ*, Hort. (*B. metálica*  $\times$  *B. echinosépala*). Plant 1–2 ft. high: sts. purple, hairy: lvs. ovate-acuminate, sinuously dentate, green and purplish above, red beneath: fls. in cymes, large, rose-colored; sepals with long hairs at the base.—Intro. 1884.

95. *cathayàna*, Hemsl. (*B. Bowringiana*, Hort., not Champ.). Fig. 524. A beautiful ornamental-lyd. species, named in 1908: sts. fleshy and crimson-hairy, 18 in. high: lvs. hanging much like the *Rex* varieties, large, obliquely cordate, long-pointed, toothed and serrate, green with crimson nerves above and bright mottled crimson beneath, very showy: fls. large for the group, vermilion. Sept. China. B.M. 8202.—It propagates readily from cuttings of both sts. and lvs. It has been hybridized with *B. Rex*, producing very richly colored foliage. *B. Bowringiana*, Champ. B.M. 5182, is distinct from *B. cathayana*, and apparently is not in cult.; but the *B. Bowringiana* of gardens, as figured in G.C. Apr. 18, 1903 suppl., is the plant here described.

96. *deliciòsa*, Lind. Plant the size of *B. Rex*, but smooth or nearly so: lvs. large, obliquely cordate-ovate, many triangular-toothed or -lobed, marked above with many gray blotches, reddish beneath: fls. in dense clusters, pink, produced in winter. Ceylon.

97. *laciniàta*, Roxbg. Erect, 1–2 ft., becoming straggling, the sts. green: lvs. roundly ovate, sharply lobed, pubescent, black-purple, with a broad zone of green, reddish on the under side: fls. as in *B. Rex*. India, S. China. B.M. 5021. G.C. III. 34:368.—Odd.

DD. *Whole plant smooth.*

E. *Lvs. thick, broad and entire, often peltate.*

98. *sanguinea*, Raddi. Fig. 525. Very smooth and shining: sts. perennial, woody at the base, red: lvs. 4–6 in. long, subpeltate, obliquely cordate, abruptly pointed, thick, fleshy, bright green above, blood-crimson below: fls. small, white. Brazil. B.M. 3520.—A handsome evergreen-foliaged begonia, notable for its brilliant red-lined thick-edged lvs.

525. *Begonia sanguinea* ( $\times \frac{1}{2}$ ) No. 98.

EE. *Lvs. medium, stiff, green and shining.*

F. *Fls. white.*

99. *angulàris*, Raddi (*B. zebrina*, Hort.). Smooth, shrubby, very tall (to 8 ft.), much branched, the branches spreading or drooping: lvs. elongate, ovate-acuminate, shiny dark green, veins white, pale green and reddish tinged beneath, the margins undulate and crenate-serrate: fls. small ( $\frac{3}{4}$  in. across) and many in large cluster, white. Brazil. B.M. 7842.—A striking plant.

100. *ulmifolia*, HBK. (*Donaldia ulmifolia*, Klotzsch). Tall, green, the st. 4-angled and grooved, shedding its hairy scurf: lvs. small and elm-like (whence the name), thinly hairy, green on both sides: fls. white, small. Colombia. Gt. 1854:93.—Very free-flowering when grown large, the fls. appearing in winter and early spring.

526. *Begonia nitida* ( $\times \frac{1}{2}$ ).  
No. 104.

101. *longipes*, Hook. Tall and stout (3 ft. or more), the st. furrowed and more or less glandular but otherwise the plant green, smooth and shining: lvs. ample, reniform or nearly orbicular, oblique or lop-sided, glossy, serrate: fls. small, white, numerous in a long-stalked cluster, winter-blooming. Trop. Amer. B.M. 3001.—In some forms, the peduncles are excessively long.

102. *undulata*, Schott. Plant green and shining, although somewhat hairy when young: lvs. 2-ranked, oblong, very short-stalked, acuminate, wavy or undulate on the margins: fls. rather small, white, in short axillary clusters, the pistillate ones long. Brazil. B.M. 2723.

103. *kewensis*, Hort. Like *B. undulata*: slender, with spreading or drooping leafy branches: lvs. ovate to cordate-ovate about 6 in. long, smooth and shining, green: fls. many, in large clusters, small, white or slightly cream-colored,  $\frac{1}{2}$  in. across. Of garden origin.—There is a hybrid between this and *B. coccinea*. A good basket plant.

FF. Fls. colored.

104. *nitida*, Dry. (*B. minor*, Jacq. *B. speciosa*, Hort. *B. obliqua*, L'Her.). Fig. 526. Smooth: st. 3-4 ft. high, perennial, fleshy, woody at the base when old: lvs. obliquely ovate, wavy, 4-6 in. across, glossy dark green: fls. on long, axillary peduncles, pale pink, with a silvery blush; males  $1\frac{1}{2}$  in. across, with 2 broad and 2 narrow petals; females smaller, with 5 equal petals. Jamaica. B.M. 4046. A.G. 24:575. Gt. 2:192.—A very useful plant in the greenhouse, flowering all winter. Also interesting on account of being probably the first begonia intro. to cult. in Eu. (1777, at Kew, by Wm. Brown). Var. *odorata alba* is a very handsome variety of this species, which has smaller fls. of the purest white and sweet-scented. Dr. Nachtigal (*B. nitida* var. *odorata alba*  $\times$  *B. Lyncheana*), is similar in general form to the latter, but has fls. of a delicate rose-pink, especially on the inner surface of petals.

105. *Teuscheri*, Lind. Stout: st. 2-6 ft. high, erect, strong grower: lvs. large, oblique, fleshy, acutely lobed, ovate-lanceolate, margins serrate, bright green above, with large grayish blotches or in one form with dots, red and strongly veined beneath: fls. in axillary clusters, bright red, large. Malaya. I.H. 26:358.

106. *Bismarckii*, Veitch. Lvs. large and lobed, oblique, acuminate-pointed, 6 in. long: fls. in drooping clusters, satiny rose, males insignificant, females  $1\frac{1}{2}$  in. across and making a gorgeous display.—Very similar to *B. Teuscheri*.

107. *carinata*, Veitch. A handsome hybrid, the result of a cross between *B. coccinea* and *B. Dregei*: plant erect or nearly so, branching freely: st. green, shining: lvs. obliquely ovate-acuminate, deeply toothed, light green: fls. rosy scarlet in large pendulous cymes.—The male fls. do not remain on the plant long, the main feature being the large bright rosy scarlet female fls. and their brightly colored ovaries which remain on the plant for a considerable period. In this respect it greatly resembles its parent, *B. coccinea*. It is a very fine greenhouse plant and should be in every collection.

108. *polyantha*, Hort. Sts. green, red at the nodes, erect, free-branching: lvs. elliptic, rich green, glabrous or nearly so; petioles reddish green, 2-3 in. long: infl. numerous, 10-20-fl.; fls. pink,  $\frac{3}{4}$ -1 in. diam. Mex.—A strong-growing species of quick growth and producing a mass of charming fls. all over the plant in winter and early spring. One of the finest and best of the winter-flowering begonias. The plants often supplied as *B. natalensis* are said to be this species.

109. *coccinea*, Hook. (*B. rubra*, Hort. *B. maculata* var. *corallina*, Hort.). Fig. 527. Smooth: sts. tall, succulent: lvs. on short petioles, obliquely oblong, angular, with wavy red margins, 4-6 in. long: fls. deep coral-red; males  $\frac{1}{2}$  in. across, with 4 unequal petals; females more attractive, owing to the length and rich color of the

527. *Begonia coccinea* ( $\times \frac{1}{2}$ ). No. 109.

ovary, which has 3 small subequal wings. Brazil. B.M. 3990.—The fls. are very persistent and exceedingly ornamental, especially when planted out. Thrives well in a warm airy greenhouse. One of the most attractive and best-known members of the genus. It has been largely used by the hybridist, the well-known

President Carnot being one of its offspring. Intro. from the Organ Mts. of Brazil by William Lobb in 1841.

EEE. *Lvs. medium to large, the margins strongly toothed, incised or lobed.*

*F. Fls. white.*

110. *Madame de Lesseps*. Fig. 528. Showy, strong, erect grower: *lvs. acutely lobed, large, margins serrate, green above, red and strongly veined below: fls. large, white, in axillary clusters, males small.* Garden origin.

528. *Begonia Madame de Lesseps* ( $\times \frac{1}{2}$ ). No. 110.

111. *Olbia*, Kerchove. Erect, the st. 2-3 ft. high: *lvs. lobed, hairy and olive-green above, smooth and red beneath, margins reddish, petioles grooved, smooth, veins prominent as dark lines: fls. concealed by lvs., in small clusters directly on the st. without peduncles, large, white, male and female in same cluster.* Brazil.

*FF. Fls. colored, varying to tinted white.*

112. *argenteo-guttata*, Hort. (*B. albo-picta*  $\times$  *B. olbia*). Fig. 529. Profusely branching: *lvs. shining green, ovate-acuminate, slightly lobed, smooth, 2½ in. wide, 3-5 in. long, thickly dotted with white spots: fls. in clusters, variable; petals white, tinged with pink: caps. rose-pink.*—Intro. by Lemoine, 1889. Well worth a place in a collection on account of its decorative foliage.

113. *maculata*, Raddi (*B. argyrostigma*, Fisch.). Very smooth: st. erect, 2-3 ft., branching, woody when old: *lvs. cordate, lanceolate, wavy, 4-6 in. long, upper surface sometimes with large white roundish or circular spots: fls. pale rose or white, males with 2 ovate and 2 narrow petals, females with 5 equal petals.* It includes several forms. Brazil. B.R. 666. Var. *argyrostigma picta*, Hort., is a common form, with very large white spots on the *lvs.* An old greenhouse or conservatory plant. Var. *elegantissima*, Hort., a variety with more slender habit of growth than the type and only sparingly maculated on the *lvs.*, but forming a large free-flowering specimen. Var. *Wrightii*, Hort., a variety with large *lvs.* heavily maculated with white, especially in the young state: infl. pendulous, 10-20-fl.; *fls. white*, an in. diam.; males short lived; females green-

ish white, remaining on the plant for several weeks.—This variety does not branch very freely as with the preceding variety but has the habit of sending up long stout shoots, 6 or 8 ft. high, from which the fine handsome clusters of fls. hang in the form of a chain.—*B. coralina*, Hort., is a free-flowering form, useful for conservatory, 8-10 ft. on rafters: *lvs. dark glossy green, almost covered with bright coral-red long fls. in large drooping trusses.* J.H. III. 51:339.

529. *Begonia argenteo-guttata* ( $\times \frac{1}{2}$ ). No. 112.

114. *Thurstonii*, Hort. (*B. metdillica*  $\times$  *B. sanguinea*). Smooth and shiny: st. 2 ft. high: *lvs. orbicular-acuminate oblique, rich purple, red on the under side, veins prominent: fls. insignificant, small, rosy white, on slender peduncles.* A.F. 7:729.—Excellent for bedding on the north side of a building, and as a pot-plant. Originated with C. Thurston, Paterson, N. J.

115. *dichroa*, Sprague. A tall-growing species but often remaining dwarf, woody in lower parts, habit half-pendulous: sts. green in upper parts only: *lvs. large for so dwarf a plant, elliptic-ovate, 6-12 in. long, rich green, glabrous on both sides, occasionally toothed, prominently veined: seedling plants beautifully maculated with white when young but the spotting is entirely lost in the adult stage: infl. dense, short, hidden amongst the upper lvs.; fls. large; males occasionally 2 in. diam., petals 4, rich brick-red; females smaller, ovaries brick-red shaded with white and prominently winged.* Brazil. B.M. 8412.—A distinct and handsome species, useful as a basket-plant.

116. *coronata*, Hort. (*B. carolinixifolia*  $\times$  *B. polyantha*). St. shrubby, coarse, 2-3 ft. high, covered with numerous withered stipules: *lvs. large, lobed, on long petioles: fls. pale pink, with large, somewhat drooping cymes.*

117. *phyllomaniaca*, Mart. Fig. 530. Hairy and shaggy: st. perennial: *lvs. obliquely cordate, attenuate, 4-6 in. long, slightly lacinated and fringed: fls. pale*

530. *Begonia phyllomaniaca*, showing adventitious plantlets ( $\times \frac{1}{2}$ ). No. 117.

pink. B.M. 5254. Brazil.—This species is peculiar in producing from the st., petioles and *lvs.* innumerable buds and small growths. It is one of the most interesting of plants. It is covered with small fls. in early spring.

118. *President Carnot*, (*B. coccinea*  $\times$  —?). Figs. 531, 532. Plant, 2-6 ft. high, spreading: *lvs. ovate-lanceolate, acute-lobed, ribs on the under side red: fls. in a large cluster; males small, insignificant; females large, bright red-carmine, 2 in. long, including caps.*—A striking and handsome plant and one that should be in all collections. It is of very easy

531. *Begonia President Carnot*.  
No. 118.

cult. and each shoot bears 1-3 of its immense clusters of brilliant female fls.

119. *lucérna*, Hort. Fig. 533. Hybrid of exceptional merit, with habit and constitution of President Carnot: lvs. heavily spotted with white, specially when young; fls. in long pendulous clusters that are often 1 ft. in diam.; male fls. 1 in. across; females much larger, with bright pink ovaries, giving the plant a distinctive appearance

as they persist for many weeks.—The plant succeeds well in a warm greenhouse. Should be in every collection. Named for Lucerne, where it originated. Intro. to commerce in 1903.

*B. amabilis*, Hort. A large-fl. form of the Gloire de Lorraine class, the clear brilliant pink blossoms being nearly 1½ in. across (Rochford).—*B. Balmisiana*, Ruiz (*B. populifolia*, Kunth) Var. *mitellifolia*, Dav. Tuberous rootstock: st. simple, erect, purplish, pubescent; lvs. reniform, obscurely lobed, irregularly serrate, whitish tomentose beneath: fls. pale rose, in a terminal raceme. Mex. R.H. 1911, p. 43.—*B. Barkeri*, Knowl. & Wesc. Fibrous-rooted: stiff, erect, sparsely branched: sts. somewhat woody, brown, densely hairy: lvs. peltate, ovate, acute, lobed, serrate, 5-7 in. long, light green in color; veins pale yellowish green; petioles long and fairly stout; infl. large and spreading, freely branched; fls. pink, produced in early spring. Mex.—A distinct and pretty begonia.—*B. calabárica*, Stapf. St. short and prostrate: lvs. peltate, oblique, broadly cordate-ovate, 2-3 in. long, ciliate on margins; fls. red, small. Calabar, W. Trop. Afr.—*B. crassicaulis*, Hort. (Lindl.?). Lvs. large, nearly circular, coriaceous, clear green: fls. many in vertical clusters, small, rose-white, the bloom being more beautiful than that of *B. manicata*, which it resembles.—*B. crispa*, Krelage. Fls. large, on long, erect peduncles above the lvs., the 5-8 perianth segms. crispate. Country unrecorded.—*B. cristata*, Hort. A form or race of tuberous begonias with a crested outgrowth in the center of the fl., the race is fixed and comes more or less true from seed.—*B. eldior*, Hort. Veitch, is a cross between *B. socotrana* and a tuberous begonia.—*B. Elsmeri*, Hort. Of garden origin, probably hybrid: fls. stellate, large, flesh-colored, in winter. European.—*B. Faureana*, Garn. Lvs. palmately parted to the middle into 3 or 5 main divisions and these divisions again parted or notched, beautifully colored with silvery white on a green ground and with brown-green on the ribs. Brazil. Intro. to France in 1892; named for the former President of France. I.H. 42:34.—Some at least of the *B. platanifolia* of gardens is this species.—*B. Forgetiana* Hemsl. Fibrous-rooted: nearly 2 ft., more or less branched: lvs. fleshy, glossy green, 6-7 in. long and 2 in. broad: fls. pink and white, 1 in. across, in clusters. Brazil.—Named for L. Forget, collector for Messrs. Sander. Allied to *B. undulata*.—*B. gemmata*, Hort. (*B. decora* × *B. Rex* var.). Lvs. angled, Rex-like, dotted with silver on a green ground: very attractive as a specimen plant. G.

532. *Begonia President Carnot* (× ¼).

22:123.—*B. gigantea*, Hort. Rootstock woody: st. 2-3 ft.: lvs. caudate-acuminate, becoming 1 ft. long: fls. many, small, white or pale pink. It is probably a form of garden origin.—*B. Gilsonii*, Hort. Plant, 2 ft. high: st. shrubby, coarse: lvs. large, lobed: fls. on long, erect peduncles, pale pink.—Interesting as being a double-fl. fibrous-rooted begonia. Named for Gilson, colored gardener to Mrs. Livingston, N. Y.—*B. Heddei*, Warb. Tall, branching: lvs. triangular-ovate or broadly elliptic, acuminate, jagged and notched and usually lobed toward the base, green above and red beneath: fls. light rose, borne amongst the lvs. German E. Afr.—*B. Ideala*, Hort. Veitch. Neat dwarf plant, *B. socotrana* × a tuberous begonia: 6 in.: fls. semi-double, 2 in. across, brilliant rose, long-lasting: winter. G. n. 61, p. 13. R.H. 1906, p. 131.—*B. Kümmeria*, Gilg. Fibrous-rooted: st. erect and free-branching, green suffused with red: lvs. ovate, 6 in. diam., shining, green veins and petiole red: infl. short, few-fl.; fls. bluish-white, tipped with rose; male, ¾ in. diam., female with bright yellow stigmas; ovary 3-celled bluntly triangular, swelling up to a large fleshy fr. some 2 in. long. Trop. Afr.—*B. Kunthiana*, Walp. St. erect: lvs. lanceolate, acuminate, serrate, smooth, green above, red below: fls. white, large. B.M. 5284. Brazil.—*B. Léhmbachii*, Warb. Allied to *B. Heddei*: herb, erect, 8-16 in., the sts. fleshy and red: lvs. oblique, 4-5 in. long, irregularly 5-lobed, dentate, light green and somewhat hairy above, red-green beneath: fls. axillary, small, tinted and red-striate. German E. Afr. Gt. 49:1476.—*B. Lindleyana*, Hort.—*B. incarnata*.—*B. lobulata*, A. DC. Fibrous-rooted: erect, branching: sts. light green: lvs. highly glabrous, pale green, ovate-acute, serrate, occasionally lobed, prominently veined, 6-8 in. long; petiole red: infl. rather short, densely fld.; fls. small, white. Mex.—*B. longicyma*, Bellair, is a garden hybrid of *B. Schmidtiana* and *B. semperflorens*,

533. *Begonia lucerna* (× ¼). No. 119.

of the fourth generation: much-branching, bushy: lvs. like those of *B. gracilis*: female fls. few or none, terminal; males lateral: fls. rose-tinted. R.H. 1905, p. 582.—*B. Martiana*, Link & Otto. Tuberous: st. 1-1½ ft., with erect branches, glabrous, leafy: lvs. oblique, cordate-ovate, acuminate, double toothed, 3-6 in. long: fls. solitary or clustered in axils, large, rose-pink, the males 4-merous and females 5-merous. Mex. Vars. *grandiflora*, *pulcherrima* and *racemiflora* are known to growers. B.M. 8322. All considered to be forms of *B. gracilis* (p. 474).—*B. Patria*, Hort. A garden hybrid of *B. socotrana* and *B. Pearcei*: plant dense and free-flowering, 10-12 in.: fls. many, rather small, bright rose-pink: lvs. similar to those of *B. socotrana*. (Lemoine).—*B. Pögei*, Warb. Fibrous-rooted: erect or spreading: sts. terete, woody in lower part, dull brownish green: lvs. only slightly oblique, elliptic, 4-6 in. long, dark green above, suffused with red beneath: infl. in short axillary clusters; fls. small, white veined with red, female with rather narrow petals; ovary distinct terete, not winged, bright red, 1-2 in. long; whole plant covered with rufous hairs. A remarkably distinct begonia, but of little horticultural value.—*B. pruinata*, A. DC. St. erect or spreading, seldom branched, covered with greenish white spots: lvs. peltate, fleshy, on long terete petioles, spreading or erect; blades broadly ovate, lobed and undulate, dark green above, with prominent veins of a greenish yellow color, and dull grey beneath: infl. erect, large, branching freely: fls. pure white. Costa Rica. A fine winter-flowering species.—*B. pyramidalis*, Lemoine. *B. manicata* × *B. carolinifolia*: lvs. large, palmate, entire, thick, brilliant green: fls. large, in panicles, white-rose or rose-tinted.—*B. Queen*. A garden hybrid: fibrous-rooted: erect with brilliant-colored foliage: sts. green, terete: lvs. ovate-acuminate, undulate, finely serrate, upper side a brilliant purple-red, the veins being green, under side bright red: fls. rosy red seldom produced. One of the finest and most ornamental of the fibrous-rooted begonias. It is somewhat difficult to grow into a large specimen and should be kept slightly drier at the roots than most plants of this section.—*B. Reichenheimii*, Hort. (*B. rubella* × *B. heracleifolia*). Lvs. all basal, large and long-petioled, parted to the middle: fls. on sts. upright above the lvs. Gt. 52, p. 207.—*B. Rochfordii*, Hort., is a bright rosy carmine begonia of the Gloire de Lorraine type, with larger fls. and foliage. F.E. 31 (1911), p. 434.—*B. Saulii*, Hort., named for the

late John Saul, was intro. from Guatemala: resembles *B. Feastii* in the shape and color of its lvs., but with a distinct red sinus at junction of petiole with lf. Probably not now cult. under this name.—*B. scéptrum*, Hort. Erect, sparsely branched: sts. light brown colored with red on young growth: lvs. large, broadly ovate, deeply lobed, margins serrate, pale green suffused with red and irregularly blotched with white, prominently veined on the underside; petioles bright red: fls. 10–20 in a cluster, pink or white.—*B. stigmōsa*, Lindl. St. a short, creeping rhizome: lvs. large, cordate-acute, irregularly toothed, smooth above, hairy beneath, green, with purple-brown blotches: fls. insignificant, white, in cymose panicles. Mex.—*B. Stürzii*, Hort. A floriferous form of *B. semperflorens*, with rose-pink fls. in broad panicles, and lvs. white-spotted.—*B. subpeltata nigricans*, Hort. (*B. nigricans*, Hort.). Plant 2–3 ft. high: lvs. ovate, acuminate, blood-red below, silvery and slightly hairy above, 4–8 in. long, 2–4 in. across: fls. rose-pink, profuse: caps. wings equal, pink. Very useful for decoration. Var. *Pres. de Boureuilles*, Hort., has lvs. of a much richer color, and more profusely studded with red hairs: fls. of a deeper pink.—*B. Tempelii*, Hort. Sport from *B. phyllomania* var. *variegata*: differs in having its regular blotches over the face of the lvs. varying from true yellow to light sulfur-color, often with blending of shades of pink: 2½–3 ft.: lvs. oblique, the margins ruffled and fringed. Originated with H. G. Wolfgang, of the Templin Co., Calla, Ohio, and put in the trade in 1905. F.E. 18:258.—*Trees*. A group of large-growing begonias produced by Mrs. Theodosia B. Shepherd, Calif. Some of them are described as a cross of Gloire de Joug by Rubra, having the cane-like growth of Rubra (*B. coccinea*), with its long-stemmed fls. but larger sepals and pistils; lvs. illuminated with red, terra-cotta, pink and yellow. Other giants are seedlings of Pink Rubra, with stronger canes, larger lvs., and more beautiful fls., the lvs. on young growth spotted with silver (Princess Alice, Rubra Bamboo, Striking Beauty, Hebe and others, are of this parentage).—*B. unifolia*, Rose. A singular begonia from Mex., recently described (Rep. Mo. Bot. Gard., 1904, p. 79, Fig. 28): tuberous-rooted: lf. 1, lying on the ground, sessile, nearly orbicular, double-toothed: fls. on slender scape to 2 ft. high, nearly white. Not in the trade.—Voss has called the hybrids of the rhizomatous group *B. rhizophōrida* and of the fibrous-rooted upright caulescent group *B. caulohōrida*; these names represent such various and often unlike forms that they will probably have little application in common practice, although useful for taxonomic purposes.

L. H. B.

**BELAMCÁNDA** (East Indian name). *Iridaceæ*.

**BLACKBERRY LILY. LEOPARD FLOWER.** A hardy, herbaceous perennial, which is an old garden favorite. The first of the popular names comes from the clusters of shining black roundish seeds, and the second from the flower, which is orange, spotted red. It is more commonly sold as a *Pardanthus*, which also means leopard flower.

Perianth segms. oblong, the 3 inner slightly shorter and spirally twisting as they fade: stamens in one group only at the base: caps. pear-shaped, the valves ultimately falling away. Prop. by seeds or by division. Of easy culture in rich, sandy loam and in a sunny place. Sometimes, but incorrectly, spelled *Bellemcanda*. One species.

*chinensis*, DC. (*Gemmingia chinensis*, Kuntze. *B. punctata*, Moench. *Ixia chinensis*, Linn. *Moræa chinensis*, Thunb. *Pardanthus chinensis*, Ker. *P. sinensis*, Van Houtte). Fig. 534. Height 2–3 ft.: rootstock short, stoloniferous lvs. about 6, equitant, striate, 1–1½ ft. long, 1 in. broad: outer spathe-valves ½–1 in. long: pedicels 1–2 in. long:

534. *Belamcanda chinensis*. (× ¼)

caps. 1–1½ in. long; valves reflexing, persistent. China and Japan. B.M. 171 (as *Ixia*). F.S. 16:1632. L.B.C. 19:1874.—The seed-stalks are sometimes used with dried grasses for decoration. It is said that the birds sometimes mistake the seeds for blackberries. N. TAYLOR.†

**BELGAUM WALNUT:**  
*Aleurites*.

**BELLADONNA:** *Atropa*.

**BELLADONNA LILY:**  
*Amaryllis*.

**BELLFLOWER:** *Campanula*.

**BELLIDIÁSTRUM** (*daisy* and *star*), is now referred to *Aster*. **B. Michéllii**, Cass. (*Aster Bellidiástrum*, Scop.), is a small European composite, 1 ft., perennial, with white heads single on naked scapes and lvs. in a rosette, sometimes planted but probably not in Amer.

535. *Bellis perennis*. (× ½)

**BÉLLIS** (Latin, *bellus*, pretty). *Compōsitæ*. **ENGLISH DAISY.** The true daisy: a low perennial with single heads on scapes, planted in borders and edgings and naturalized in grass land. Fig. 535.

The daisy, as it grows wild in England, has a yellow center, surrounded by numerous rays in a single row, but the favorite cult. forms are double, the rays rising in tier upon tier, and frequently crowding out every trace of a yellow center. The English daisy is essentially a pink or pinkish fl. in its general effect, the tips of the rays sometimes and the under surfaces usually being pink or red. There are about 10 species in the genus, only one of which is American. *B. integrifolia* is found in moist soil from Ky. and Tenn. to Ark. and Texas, but is too rare and sectional to become a general favorite. The plant that is most commonly called daisy in Amer. is *Chrysanthemum Leucanthemum*. For a list of the various plants known as daisies in Amer., see *Daisy*.

Daisies are favorite border plants, and are much used in spring bedding, especially for edging. They thrive in a cool soil and moist atmosphere, and are, therefore, much better adapted to English than American gardens. They can be grown, however, in a cool greenhouse where they will flower profusely during February and March. Although the English daisy is a perennial, it can be very easily grown as an annual. A light mulch is desirable for winter protection. In home gardening, the plants, after flowering, are divided into single crowns. These are planted about 6 inches apart in good rich garden soil. Each crown soon sends out side growths, which, in time, form new crowns. Before winter sets in the young clumps can be moved readily to any place in the garden in which they are wanted to bloom. Daisies are also forced by florists for winter bloom. When daisies are desired for edging spring flower-beds, the clumps are divided into single plants during the previous September, or early enough to allow the new plants to get a firm hold before winter, and are placed 3 inches apart in a narrow trench. These edgings must be renewed each year, as the plants, if they grow well, spread too wide, or irregularly. In dry summers many roots fail, and if they remain in the same spot year after year, the flowers will degenerate to the single condition.

The simplest way of propagating and growing English daisies for spring bedding in this country is to

sow the seed in shallow boxes about August 10. As soon as large enough to handle, transplant 5 inches apart into coldframes, and when the winter sets in put on the sash, giving air whenever the weather may be mild. Transplant to the flower beds as early as possible in the spring, where in a very short time they will be a mass of bloom, and will continue to bloom till the beginning of June, when they should be thrown out, and the summer bedding plants put in. Longfellow and Snowball are the two best varieties for this purpose. *Myosotis alpestris* and *Silene pendula* may be grown the same way, using the daisies as edging when in the beds, and the others as center pieces.

The daisy is propagated by seeds (which are sown early), and by divisions, the choicest varieties being maintained by the latter method. The main types grown from seed are the white, rose, quilled, and white with red center, all of which are double. A dark red is less common. Of kinds propagated by seed, Longfellow is now the best rose-colored, and Snowball the best white variety, the latter being especially prized by florists for cut-flowers, as it has long, stiff stems. Other varieties are Maxima, Snowflake, and Rob Roy, which is perhaps the best red.

**perennis**, Linn. TRUE OR ENGLISH DAISY. Hardy herbaceous perennial, 3-6 in. high: lvs. clustered at the root, spatulate or obovate: fls. 1-2 in. across, solitary, on hairy scapes. Apr.-June. W. Eu.; escaped in Calif.; rarely runs wild in the eastern states. B.M. 228. F.S. 6:584, which shows 11 well-marked types.—An interesting but not permanent form is the "hen-and-chickens daisy," in which a number of small fl.-heads are borne on short stalks springing out of the main fl.-head. Cockscomb forms, in which several scapes unite to produce a monstrous fl., are sometimes seen, but cannot be perpetuated. The rays are sometimes wholly incurved, or reflexed, or quilled. Other English names of the daisy are herb Margaret, ewe- or May-gowan, childing daisy, bone- or bruisewort, bone flower, March daisy, bairnwort.

J. B. KELLER, E. J. CANNING,  
and WILHELM MILLER.

**BÉLLIUM** (from its resemblance to *Bellis*, the daisy). *Compósitæ*. Miniature plants, sometimes planted in rock-gardens.

Leaves crowded or in a rosette, from which arise scapes bearing a single daisy-like head or "flower," white, with light yellow disk: differs from *Bellis* largely in its pappus, which is unequal and double, of bristles and scales.—Four to 6 species in the Medit. region, annual and perennial. Require treatment given rock-plants and sod-plants.

**bellidioides**, Linn. Annual, 2 in., with creeping stolons: lvs. spatulate: heads white, all summer.—Like a miniature daisy. Apparently little known in this country.

L. H. B.

**BELLWORT**: In England, any member of the *Campanulacæ*. In America, *Uvularia*.

**BÉLOU** (Brahman name for the Bael fruit). *Rutacæ*, tribe *Citræ*. An older name for *Ægle*, recently reinstated by American taxonomic botanists. See description under *Ægle*.

*B. Marmelos*, A. B. Lyon, = *Ægle Marmelos*, the Bael fruit of India. *B. glutinosa*, Skoels = *Chætospermum glutinosa*, Swingle.

**BELOPERÒNE** (name refers to the arrow-shaped connective). *Acanthacæ*. Hothouse evergreen shrubs of the *Justicia* group, rarely seen in cult. and apparently not in American trade. Lvs. entire: fls. usually red or purple, mostly in showy-bracted axillary or terminal clusters; corolla-tube narrow, often long, the limb 2-lipped; stamens 2, affixed on the tube; style filiform, entire or slightly 2-lobed: fr. an oblong or ovoid caps.—About 30 species inhabiting Trop. Amer., of which 2 or 3 are listed as cult. plants. *B. violacæa*, Planch. &

Lind., has lanceolate-acuminate lvs. and violet-purple fls. B.M. 5244. *B. oblongata*, Lindl., has oblong-lanceolate lvs. and axillary spikes of rose-purple fls. B.R. 1657. A recent species is *B. angustiflora*, Stapf, resembling *B. violacæa*, with oblong-elliptic lvs. and a very narrow corolla-tube with a violet-purple limb.

**BELVIDERE**, or SUMMER CYPRESS: *Kochia*.

**BENE**: *Sesamum*.

**BENI, JAPANESE**: *Caroypteris Mastacanthus*.

**BENINCÀSA** (name of an Italian nobleman). *Cucurbitacæ*. Annual running squash-like herbs grown sparingly for the edible fruits.

Leaves 5-lobed soft-hairy: fls. solitary, yellow, monœcious, the staminate long-peduncled, the pistil-

536. *Benincasa hispida*.

late nearly sessile; corolla deeply lobed; tendrils 2-3-branched.—Two species in Trop. Asia.

**hispida**, Cogn. (*B. cerifera*, Savi). Fig. 536. WAX GOURD. WHITE GOURD OF INDIA. ZIT-KWA. CHINESE PRESERVING MELON. CHINESE WATERMELON. Vine long, like a muskmelon, hairy, with cordate lobed lvs.: fr. mostly oblong, 10-16 in. long, hairy, white-waxy, with solid white flesh and small cucumber-like seeds. Cult. the same as muskmelon or cucumber. R.H. 1887:540.—Used for making preserves and sweet pickles; said to be eaten raw in warm countries, and the unripe frs. to be employed by natives in India in the making of curries.

L. H. B.

**BENJAMIN BUSH**: *Benzoin æstivale*.

**BENT-GRASS**: *Agrostis*.

**BENTHÂMIA**: *Cornus*.

**BENTINCKIA** (named for Lord Bentinck, governor of Madras, 1803-1805). *Palmacæ*, tribe *Géonomææ*. Tall stately unarmed palms, with equally pinnate, terminal leaves; not as yet well known to the trade, but deserving greater attention.

Leaves of many lfts. which are usually 2-lobed at the apex: spathes many, the 2 lower short and incomplete; spadix arising from among the lvs., branched; fls. small, monœcious or polygamous: fr. small, almost round, with a single seed pendulous from the top of the cavity.—There are only 2 species, both Indian. G.C. II. 22:595.

The following is a graceful palm "in general appearance not unlike the coconut palm, than which it is, however, much more graceful." The young leaves for the first year are bi-partite, quite like young coconut palms.

They should be grown in a warmhouse, never less than 60°, and should be given plenty of water at all seasons. A mixture of rich loam and peat or leaf-mold, half and half, makes the best medium for growth.

**nicobàrica**, Becc. ORANIA. St. 50-60 ft., solitary, usually from 7-10 in. thick: lvs. 5-8 ft. long; lfts. 1-2 ft., sessile, linear and leathery, the tips distinctly 2-lobed; petiole and rachis glabrous, the former short:

spadix 1½–2 ft., many times branched, the branchlets inserted in woolly grooves: fr. about as large as a cherry. India. R.H. 1896, p. 249. N. TAYLOR.

**BÉNZOIN** (of Arabic or Semitic origin, meaning a gum or perfume). Syn., *Lindera*. Lauraceæ. Ornamental woody plants, grown chiefly for their handsome aromatic foliage; some species also for their early yellow flowers and the brightly colored fruits in autumn.

Aromatic shrubs or trees: lvs. alternate, entire or 3-lobed, deciduous or persistent: fls. polygamous or dioecious, apetalous, small, in axillary clusters with an involucre of 4 deciduous scales; sepals 6, rarely more; staminate fls. with 9 stamens, pistillate with a globose ovary and 9–15 staminodes: fr. a 1-seeded drupe. —About 60 species, if *Daphnidium* and *Aperula* are included, in Temp. and Trop. E. and Cent. Asia and in N. Amer.

Some Asiatic species yield an odorous oil used in perfumery. The cultivated species, with the exception of *B. gracile*, are deciduous shrubs, with yellow flowers in small clusters before the leaves and red or black fruits in autumn. *B. æstivale* is hardy North and *B. obtusilobum* has proved hardy at the Arnold Arboretum in a sheltered position; *B. hypoglaucum* is of about equal hardiness; the other species are more tender.

They thrive best in peaty or sandy and moist soil. Propagation is usually by seeds, which must be sown after maturity, as they soon lose their vitality; also by layers, which root best in peaty soil; of greenwood cuttings under glass, one-half may be expected to root. The benzoin of the druggists is a balsamic resin obtained from *Styrax Benzoin*.

*æstivale*, Nees (*Bénzoin Bénzoin*, Coulter. *B. odoriferum*, Nees. *Lindera Bénzoin*, Blume). SPICE BUSH. BENJAMIN BUSH. WILD ALLSPICE. FEVER BUSH. Fig. 537. Shrub, 6–15 ft., nearly glabrous: lvs. oblong-obovate, finely ciliate, bright green, pale beneath, 3–5 in. long: fls. yellow, before the lvs.: berry red, oblong, spicy. New Eng. southward and west to Kan. Em. 365.—The bark is aromatic, stimulant, tonic, astringent; the fr. is likewise used medicinally. The shrub is attractive in early spring with its yellow, small, but numerous fls., and handsome in autumn with its foliage turning clear yellow and studded with the scarlet frs.

*B. gracile*, Kuntze (*Daphnidium gracile*, Nees). Lvs. ovate, 3-nerved, chartaceous, persistent. Habitat unknown. Stove plant. —*B. hypoglaucum*, Rehd. (*Lindera hypoglaucum*, Maxim. *B. hypoleucum*, Kuntze). Lvs. penninerved, glaucous beneath: clusters few-fl., with or before the lvs.: berries black. Japan. —*B. melissifolium*, Nees. Allied to *B. æstivale*. Branches pubescent: lvs. oblong, downy beneath. Southern states. B.M. 1470. —*B. obtusilobum*, Kuntze. Large shrub with very handsome foliage: lvs. 3-nerved, ovate or 3-lobed, grayish green and nearly glabrous beneath, 2–4½ in. long: clusters many-fl.: berries black. Japan. G.F. 6:295. S.I.F. 1:44. —*B. præcox*, Sieb. & Zucc. Lvs. penninerved, elliptic-oblong, greenish beneath, acuminate: clusters few-fl., before the lvs.: berries brownish, ½ in. diam. Japan. S.I.F. 2:19. —*B. sericeum*, Sieb. & Zucc. Lvs. penninerved, grayish pubescent beneath: clusters many-fl., with the lvs. Japan.

ALFRED REHDER.

**BERBERIDOPSIS** (from *Berberis* and Greek *opsis*, likeness). Flacourtiaceæ. Ornamental shrub cultivated for its crimson flowers and evergreen foliage.

Branches slender, terete: lvs. alternate, petioled, dentate: fls. perfect, long-pedicelled, in terminal racemes; bracts, sepals and petals gradually passing into one another, 9–15, the inner ones concave, larger; stamens 7–10 with very short filaments; ovary superior, 1-celled with many ovules; style short, with 3-lobed stigma: fr. a berry. —One species in Chile.

This is a low, glabrous, slightly climbing shrub, with deep green foliage and crimson flowers in drooping racemes, for temperate regions or the cool greenhouse, growing in almost any soil. Propagation is by seeds sown in spring, by greenwood cuttings in spring, or by layers in autumn.

*corallina*, Hook. Lvs. cordate, oblong-ovate, coarsely spinulose-dentate, 2–3 in. long: fls. globose, over ¼ in. long, crimson, in many-fl. bracteate racemes. B.M. 5343. F.S. 20:2137. F.W. 1875:97. G. 2:547. 32:175. H.F. 1863:148.

ALFRED REHDER.

**BÉRBERIS** (Arabic name). *Berberidaceæ*. BARBERRY. Ornamental deciduous or evergreen shrubs, cultivated for their handsome foliage assuming in most species brilliant autumnal tints, and for their bright yellow flowers and attractive fruit.

Spiny shrubs with yellow inner bark and wood: lvs. alternate, often fascicled, usually glabrous, simple, deciduous or evergreen: fls. in elongated or umbel-like, rarely compound racemes, or fascicled or solitary; sepals 6 with 2 or 3 bractlets below; petals 6, often smaller than sepals and usually with 2 glands near the base; stamens 6, included, the anthers opening with valves; ovary superior, 1-celled, with 1 to many ovules: fr. a berry with 1 or several oblong seeds. —Nearly 175 species in Amer. from Brit. Col. to Patagonia, in Asia, Eu., and N. Afr. Monogr. by Schneider in Bull. Hort. Boissier, Ser. II. 5:33, 133, 391, 449, 655, 800, 813 (1905). Mahonia is now considered by most botanists as a distinct genus, differing from the true barberries by the pinnate lvs., by the racemes appearing in the axils of the bud-scales and by the spineless branches. The spines of the barberry are, morphologically, lvs., and the lvs. are borne on short branches in their axils (Fig. 538). The stamens are sensitive; when the filaments are touched with a pin, the fls. first open, and the stamens fly forward upon the pistil. ALFRED REHDER.

The different species of hardy deciduous barberries are excellent decorative shrubs with pleasing habits of growth. The flowers of most of them in spring and early summer, whilst not conspicuous, are very attractive, and the fruits of nearly all are highly ornamental in late summer, fall and early winter on account of their red, dark blue or nearly black color. *Berberis amurensis*, *B. sinensis*, *B. diaphana*, *B. Poiretii*, *B. Regeliana*, *B. Sieboldii*, and *B. Thunbergii* all assume brilliant fall colors in varying shades of orange and red. Some species, as *B. Thunbergii*, *B. Sieboldii*, and *B. Rehderiana*, retain their bright red fruits unchanged until the following spring, while the fruits of the other species shrivel and dry up during the winter.

*Berberis aristata* is the strongest-growing species and attains a height of 12 to 13 feet in twenty years, with gracefully arching branches, and has violet-red fruits; the thickish leaves are semi-persistent. *B. canadensis* forms a neat compact bush 3 to 3½ feet with upright spreading branches. The small clusters of bright red fruits are very attractive. This is a rare shrub in cultivation, and *B. vulgaris* has often been sold for it. *B. sinensis* is a neat, graceful shrub with pendulous branches 3½ to 4 feet and bears numerous clusters of bright red fruits. *B. diaphana* forms a dense compact shrub 2½ to 3 feet, but its chief decorative value is in its rich fall coloring, as the solitary flowers and fruits

are inconspicuous. *B. Regeliana* has an upright dense habit, and grows from 5 to 6 feet. It has the largest leaves of any of the deciduous species, and the orange-red fruits are remarkably ornamental throughout late summer and fall, until midwinter. This is perhaps the most beautiful barberry in cultivation. *B. Sieboldii* is slow-growing, but is a very choice species. The habit is upright and compact, and the fall coloring is brilliant. The small vermilion-red fruit-clusters are very attractive. *B. vulgaris*, which is commonly grown and has become extensively naturalized, has large clusters of brilliantly colored fruits, and is a most useful shrub in border plantations. It is prolific in many varieties. Perhaps the most distinctive form is the one with yellow fruits, which are usually seedless, or, if the seeds are present, they are abortive. This species makes a good hedge plant as does also *B. amurensis*; for low ornamental hedges, *B. Thunbergii* is excellent. Since it makes a rather broad hedge, the plant is most beautiful when it is not necessary to trim it. *B. Wilsonæ* is a small beautiful shrub, 2 to 2½ feet with slender branches and small leaves. The coral-red fruits are very distinctive. The tips of the branches usually are winterkilled, but the plants recover rapidly in summer.

Few of the evergreen species are dependable in the northeastern states. *B. Sargentiana*, a handsome shrub, attaining a height of about 6 ft., with rather large oblong leaves, has proved quite hardy, and *B. burifolia*, *B. stenophylla* and *B. verruculosa* nearly hardy in Massachusetts. *B. Neubertii* rarely has the leaves scorched by winter's cold, but is very slow-growing. For other evergreen species, see *Mahonia* (formerly included in *Berberis*).

The root and the inner bark of several species are sometimes used for dyeing yellow. Some species have medicinal properties. The fruits of *B. vulgaris* are made into jelly. In wheat-growing districts, planting of *Berberis* should be avoided, as it is the host of the æcidium stage of *Puccinia graminis*, a fungus which causes the wheat-rust. Destroying the *Berberis*, however, will not check the propagation of the fungus, as it is able to grow and to spread for years without forming the æcidium stage.

To secure the best results from most of the barberries, they should be planted in moist, light loam, well drained. The deciduous species, however, can be grown in drier situations.

Barberries germinate readily from seeds. The seeds should be separated from the pulp by maceration and sown in "flats" or broadcast in beds in the fall, and they will germinate the following season. The seeds of rare and scarce species should be sown in the greenhouse where they will germinate during the winter. *Berberis Wilsonæ* will germinate in two to three weeks in the greenhouse if sown as soon as ripe. Some of the species cross when grown together, but *B. sinensis*, *B. Regeliana* and *B. vulgaris* appear to come true. The progeny of *B. Thunbergii* sometimes seem to show that they have been affected by the pollen of *B. vulgaris*.

Most of the barberries can be propagated from the green cuttings of the young wood taken from the first to the middle of June, and placed in sand in a shaded hotbed in precisely the same way as lilacs, viburnums or hydrangeas are treated. This is the best way to perpetuate individuals of strikingly characteristic habits. A very small percentage of the cuttings of the ripe wood placed in the greenhouse in the fall will "strike," but not enough to pay. Some species may be propagated by suckers. Rarer kinds and varieties are sometimes grafted on *B. vulgaris* or *B. Thunbergii*, in August or September under glass, or in early spring in the greenhouse. Grafting, however, is not to be recommended, for the stock usually throws up suckers which are often overlooked on account of the similarity of the foliage of many species; they will overgrow the cion

in a short time and smother it. A good plan is to use the purple-leaved barberry as a stock; the suckers are thus easily noticeable and may be removed in time.

JOHN DUNBAR.

## KEY TO THE SPECIES.

- A. Foliage deciduous; lvs. membranous or chartaceous.
- B. Fls. in elongated racemes or panicles (few-fl'd. peduncled umbels in No. 7).
- C. Lvs. dentate or serrate.
- D. Infl. simple, racemose.
- E. Branches of last year gray, except those of the purple-ld. form of No. 1.
- F. Texture of lvs. rather thin, not distinctly reticulate beneath.
- G. Shape of lvs. generally obovate; setulose-dentate.
- GG. Shape of lvs. oblong or elliptic; densely ciliate-dentate.
- FF. Texture of lvs. firmer than in F, distinctly reticulate beneath, often obtuse.
- EE. Branches of last year reddish brown or yellowish brown.
- F. The lvs. spinulose-dentate.
- G. Fr. purplish blue, oblong-ovoid, longer than the stout pedicels: racemes longer than the lvs.
- GG. Fr. red, short-ovoid, shorter than the slender pedicels.
- H. Breadth of lvs. ⅓-¾ in., oblong-obovate to obovate, scarcely reticulate.
- HH. Breadth of lvs. ¾-1½ in., usually obovate, reticulate, rounded at the apex.
- FF. The lvs. densely setose-ciliate, oblong; racemes umbel-like, 3-6-fl'd.
- DD. Infl. compound, paniculate, 2-6 in. long.
- E. Branches angled, grayish brown; lvs. rounded at the apex, subcoriaceous.
- EE. Branches nearly terete, brown; lvs. acute, thin.
- CC. Lvs. entire, at least those of the flowering branches.
- D. Fr. red or purple; lvs. narrow-obovate or oblanceolate, acute or acutish, bright green.
- E. Bracts at least half as long as the short pedicels: lvs. green beneath, usually narrow-ob-lanceolate, entire.

1. vulgaris

2. amurensis

3. Regeliana

4. aristata

5. canadensis

6. koreana

7. Sieboldii

8. polyantha

9. Francisci-Ferdinandi

10. Poiretii

- EE. Bracts much shorter than the elongated pedicels: lvs. grayish or bluish gray beneath, those of the shoots often spinulose, broader. . . . . 11. *sinensis*
- DD. Fr. bluish or purplish black, bloomy: lvs. usually grayish or bluish green, broadly obovate to oblong-obovate. . . . . 12. *heteropoda*
- E. Racemes short, usually 5-7-fld.: branches slightly angular: ovules slender-stalked. . . . . 12. *heteropoda*
- EE. Racemes many-fld., dense: branches terete: ovules short-stalked. . . . . 13. *integerrima*
- BB. Fls. solitary or sometimes in few-fld. umbels or in dense fascicles (in a variety of No. 14 in 3-10-fld. short racemes).
- C. Lvs. always entire.
- D. Young branchlets glabrous: lvs. not reticulate, generally obovate,  $\frac{1}{2}$ - $1\frac{1}{2}$  in. long: fr. scarlet, rather dry. . . . . 14. *Thunbergii*
- DD. Young branchlets puberulous: lvs. reticulate, generally oblanceolate,  $\frac{1}{4}$ -1 in. long: fr. salmon-red, juicy. . . . . 15. *Wilsonæ*
- CC. Lvs. partly dentate, partly entire.
- D. Pedicels  $\frac{1}{2}$  in. long: lvs. chalky white beneath, not reticulate, less than 1 in. long: fr.  $\frac{1}{2}$  in. long. . . . . 16. *dictyophylla*
- DD. Pedicels  $\frac{1}{2}$  in. long; fls. nodding: lvs. glaucous beneath, reticulate, more than 1 in. long: fr. nearly  $\frac{1}{2}$  in. long. . . . . 17. *diaphana*
- AA. Foliage persistent or half-evergreen.
- B. Lvs. entire.
- C. Shape of lvs. obovate or elliptic: fls. solitary, long-pedicelled. . . . . 18. *buxifolia*
- CC. Shape of lvs. narrow-oblong to linear, revolute at the margin.
- D. Fls. 1-2, long-pedicelled: lvs. linear. . . . . 19. *empetrifolia*
- DD. Fls. 2-6, in peduncled umbels: lvs. narrow-oblong. . . . . 20. *stenophylla*
- BB. Lvs. dentate.
- C. Fls. in fascicles or solitary.
- D. Lower surface of lvs. white or glaucous,  $\frac{1}{2}$ -1 in. long: fls. 1-2.
- E. Branchlets angled, smooth. . . . . 21. *concinna*
- EE. Branchlets terete, densely verruculose. . . . . 22. *verruculosa*
- DD. Lower surface of lvs. green: fls. several to many.
- E. Shape of lvs. oblong to narrow-lanceolate, with many teeth.
- F. Texture of lvs. rather thin; lvs. usually about  $\frac{1}{2}$  in. broad, indistinctly veined.
- G. Pedicels slender,  $\frac{1}{2}$ -1 in. long; fls. 3-8: lvs. with 8-20 teeth on each side: fr. bluish black, bloomy. . . . . 23. *Gagnepainii*
- GG. Pedicels  $\frac{1}{4}$ - $\frac{1}{2}$  in. long; fls. many: lvs. with 5-12 teeth on each side: fr. jet-black. . . . . 24. *levis*
- FF. Texture of lvs. thick and firm; lvs.  $\frac{3}{4}$ - $1\frac{1}{4}$  in. broad: fls. many; pedicels about  $\frac{1}{2}$  in. long: fr. black. . . . . 25. *Sargentiana*
- EE. Shape of lvs. roundish to elliptic, with 3-6 teeth: fls. in dense globose clusters. . . . . 26. *hakeoides*
- GC. Fls. in racemes or panicles.
- D. Branches spiny; young branchlets pubescent or puberulous: lvs. always simple.
- E. Racemes simple.
- F. Ovary with long style: lvs. green beneath.
- G. Branchlets puberulous: lvs. 1-2 in. long: racemes shorter than lvs., 4-10-fld. . . . . 27. *ilicifolia*

- GG. Branchlets hairy: lvs.  $\frac{1}{2}$ - $1\frac{1}{2}$  in. long: racemes longer than lvs., many-fld. . . . . 28. *Darwinii*
- FF. Ovary with short style: branchlets puberulous: lvs. whitish beneath, 1- $2\frac{1}{2}$  in. long. . . . . 29. *asiatica*
- EE. Racemes compound: lvs. obovate-oblong, with few teeth above the middle or entire, 1- $2\frac{1}{2}$  in. long. . . . . 30. *chitria*
- DD. Branches spineless, glabrous: lvs. occasionally 3-foliate, half-evergreen. . . . . 31. *Neubertii*

1. *vulgâris*, Linn. COMMON BARBERRY. Fig. 538. From 4-8 ft., rarely 15: branches grooved, gray, upright or arching: lvs. oblong-spatulate or obovate, setulose-dentate, pale or grayish green beneath, membranous, 1-2 in. long: racemes pendulous, many-fld.; fls. bright yellow: fr. oblong-ovoid, scarlet, finally purple. May, June: fr. Sept., Oct. Eu. to E. Asia; escaped from culture and naturalized in E. N. Amer. Gn. 35:264.— Handsome in spring, with its golden yellow fls. and light green foliage; and in fall, with its bright scarlet frs., remaining through the whole winter. A very variable species. Of the many garden forms, the most effective is var. *atropurpurea*, Regel (var. *purpurea*, Hort., not Loud., which is a form with purple fr.), with purple-colored lvs. (Gt. 9:278, 1); little different is var. *macrophylla*, Kew Bull. (*B. vulgâris foliis purpurea macrophylla*, Paul & Sons), with larger lvs. of deep purple color. Other varieties are: Var. *albo-variegata*, Zabel, lvs. variegated with white, rather small; Var. *aureo-marginata*, Zabel, lvs. with yellow margin, rather large; var. *alba*, Don (var. *leucocarpa*, Hort.), white-fruited; var. *asperma*, Don (var. *apirena*, Hort.), seedless; var. *dulcis*, Loud. (var. *edulis*, Hort.), less acid; var. *lutea*, Don (var. *xanthocarpa*, Hort.), yellow-fruited; var. *macrocarpa*, Jaeger, with larger fr. The forms with black or purplish blue fr., as var. *nigra*, Don, and var. *violacea*, Don, do not belong here, but are either hybrids or belong to other species.

538. *Berberis vulgaris*. ( $\times \frac{1}{2}$ ). Showing the spines and foliage.

2. *amurënsis*, Rupr. (*B. vulgâris* var. *amurënsis*, Regel). Three to 8 ft.: branches straight, gray, upright, grooved: lvs. cuneate, oblong or elliptic, densely ciliate-dentate, slightly reticulate and bright green and lustrous beneath, 1-3 in. long: racemes upright or nodding, 6-12-fld., about as long as lvs.: fr. oblong-ovoid, scarlet. May: fr. Sept. Manchuria, N. China. Gng. 5:119. G. W. 7, p. 413. See page 3566.

3. *Regeliâna*, Koehne (*B. vulgâris* var. *japonica*, Regel. *B. amurënsis* var. *japonica*, Rehd. *B. japonica*, Schneid., not DC. *B. Sieboldii*, Hort., not Miq. *B. Hakodate*, Hort.). Fig. 539. Upright shrub, to 6 ft.: branches gray, grooved: lvs. elliptic-oblong and acute, or obovate or obovate-oblong and obtuse, 1- $2\frac{1}{2}$  in. long, setulose-dentate, often rather densely so, pale or grayish green and distinctly reticulate beneath, of firm texture: racemes upright or nodding, 6-12-fld., shorter or about as long as lvs.: fr. oblong-ovoid, scarlet, with slight bloom. May, June: fr. Sept., Oct. Japan. G.F. 3:249 (adapted in Fig. 539). A.G. 18:454.

4. *aristata*, DC. (*B. coriaria*, Royle. *B. floribunda*, Wall.). Shrub, to 8 ft.: last year's branches yellowish brown, slightly angular; spines mostly simple: lvs. elliptic to ovate-oblong, acute or obtusish, spinosely dentate, occasionally entire, 1-2½ in. long, of firm texture at maturity: racemes 10-25-fld., sessile, usually spreading and stout: fr. nearly ½ in. long, longer than the stout pedicels, bright red, finally bluish purple and bloomy; stigma on a short distinct style. June; fr. Sept., Oct. Himalayas. B. R. 27:46.—Hardy at the Arnold Arboretum. Hybrids occur with *B. vulgaris*.

5. *canadensis*, Mill. (*B. caroliniana*, Loud. *B. angulizans*, Hort.). Upright shrub, 1-3 ft., with arching branches: spines small, 3-parted: lvs. cuneate-oblong to obovate, remotely spinulose-dentate, rarely entire, usually obtusish, 1-2 in. long: racemes many-fld., longer than the lvs.; petals retuse or emarginate: fr. ovoid, scarlet. May, June; fr. Sept., Oct. Alleghanies. G. W. 1:101.—The plant sold under this name is usually *B. vulgaris*. Lower and more graceful than *B. vulgaris*; the foliage turns scarlet in autumn.

6. *koreana*, Palibin. Shrub, to 6 ft.: branches grooved, yellowish or reddish brown; spines short, scarcely ¼ in. long, usually simple: lvs. obovate, or oval, rounded at the apex, cuneate at the base, 1-2½ in. long and ½-1½ in. broad, spinose-serrulate, reticulate and pale beneath: racemes shorter than lvs., rather dense, slender-stalked, nodding: fr. subglobose-ovoid, ¼ in. long, bright red. May; fr. Sept., Oct. Korea. J.C.T. 26, 1:5.—Handsome species with broad lvs. coloring deep red in autumn and with bright red fr. persisting until the following spring; has proved perfectly hardy at the Arnold Arboretum.

7. *Sieboldii*, Miq. Shrub, to 3 ft.: last year's branches deep reddish brown, angular, 2-edged toward the end: spines 3-parted, slender: lvs. oblong-obovate, 1-2½ in. long, acute or obtusish, cuneate at the base, setosely ciliate and usually revolute at the margin, bright green below: racemes 3-6-fld., slender-peduncled, umbel-like: fr. ovoid to subglobose, ¼ in. long, rather dry, bright red and lustrous. May, June; fr. Sept. Japan. S.T.S. 1:14.—A very handsome shrub: lvs. purplish when unfolding and marked with green veins, deep vinous red in autumn: the fr. retains the bright color until the following spring. It has proved perfectly hardy at the Arnold Arboretum. Often *B. Regeliana* is cultivated under the name *B. Sieboldii*.

8. *polyantha*, Hemsl. Shrub, to 12 ft.: branches grayish brown, slightly angled, glabrous or puberulous with usually short spines: lvs. cuneate-obovate, rounded at the apex, leathery, spiny-serrate, rarely nearly entire, pale grayish green, ¾-1¼ in. long: fls. deep yellow in pendulous short-stalked panicles 2-6 in. long: fr. oblong-ovoid, narrowed into a distinct style, pale red, bloomy, ½ in. long. June, July; fr. Sept. W. China. G. 33:269.—Very handsome with its large panicles of deep yellow fls.; not quite hardy in Mass.

539. *Berberis Regeliana*.  
(× ¼)

9. *Francisci-Ferdinandi*, Schneid. Shrub, to 10 ft.: branches red-brown, nearly terete, with long spines: lvs. elliptic to ovate-lanceolate, acute, cuneate at the base, densely spiny-serrate, bright green, thin, 1-2½ in. long: fls. yellow in pendulous, usually narrow panicles, with the slender stalk 3-5 in. long: fr. ovoid-oblong, scarlet, almost ½ in. long, with nearly sessile stigma. May, June; fr. Sept. W. China.—The drooping panicles of scarlet frs. are very handsome.

10. *Poirétii*, Schneid. (*B. sinensis*, Hemsl., not Poir. *B. sinensis* var. *angustifolia*, Regel). Shrub, to 5 ft.: branches slender, arching, the younger grooved, purplish brown; spines about ½ in. long, usually simple: lvs. oblanceolate, to narrow-oblanceolate, ½-1½ in. long, entire, slightly reticulate and green beneath: racemes 8-14-fld., 1-2 in. long; pedicels scarcely ¼ in. long, bracts about half as long: fr. ovoid-oblong, deep blood-red. N. China, Amurland.—Hardy and handsome, but rare in cult. and usually confounded with the following species.

11. *sinensis*, Poir. (*B. spathulata*, Schrad. *B. ibérica*, Stev. & Fisch. *B. sanguinolenta*, Schrad. *B. Guimpelii*, Koch). From 4-6 ft., with slender, often arching branches, the younger grooved, reddish brown; spines 1-3-parted, ½-¾ in. long: lvs. cuneate, oblong or obovate-lanceolate, entire or sometimes with a few teeth, grayish green or glaucescent beneath, ½-1½ in. long: racemes pendulous, slender-peduncled, rather dense; pedicels slender, about ½ in. long, several times longer than the bracts: berries ovoid, purplish. Caucasus. B.M. 6573. G.O.H. 63. L.D. 7:487. G.W. 8:115. G. 34:379.—A hardy, graceful species, very handsome in fr.

12. *heteropoda*, Schrenk. Fig. 540. Three to 6 ft.: branches stout, spreading, the younger chestnut-brown, lustrous slightly grooved, spines sometimes to 2 in. long, often wanting: lvs. broadly obovate or oval, entire or sometimes remotely serrate, pale bluish green, 1-2 in. long, some short and some slender-petioled: fls. in stalked, usually 5-7-fld. racemes, orange-yellow, fragrant; ovules long-stalked: fr. ovoid, dark blue with glaucous bloom. May. Turkestan, Songaria. G.F. 8:455 (adapted in Fig. 540).—Handsome and very distinct species. *B. heteropoda* var. *oblonga*, Regel, see *B. oblonga* in supplementary list.

13. *integerrima*, Bunge (*B. nummularia*, Bunge). Shrub, to 6 ft.: last year's branches terete, purplish brown; spines usually simple, to 2 in. long: lvs. obovate or broadly obovate, usually entire, sometimes remotely setose-serrate, grayish green: racemes dense, usually many-fld.; fls. small, on short pedicels, about ½ in. long; ovules short-stalked: fr. black, globose-ovoid. May.—A variable species similar to the preceding.

14. *Thunbergii*, DC. Figs. 541, 542. Dense, low shrub, 2-5 ft.: branches spreading, deeply grooved, brown, with simple spines: lvs. obovate or spatulate, quite entire, glaucescent beneath, ½-1½ in. long: fls. 1-3, pale yellow: fr. elliptic or nearly globose, bright red. Apr., May. G.F. 2:53. B.M. 6646. R.H. 1894: 173. A.G. 18:357. Gng. 4:241; 5:119, 353, 355. Mn. 2:118. A.F. 8:526.—One of the most valuable species, especially remarkable for its low, dense, horizontal growth, its large brilliant red frs., remaining fresh till the following spring, and for its bright scarlet fall coloring; hardy. Very valuable for borders of walks and drives and for low ornamental hedges. Endures partial shade. Cattle and sheep do not browse it much. Var. *Maximowiczii*, Franch. & Sav., has the lvs. green beneath. Var. *pluriflora*, Koehne, has 3-10 fls. in short, umbel-like raceme. Var. *minor*, Rehd. (var. *Davsonii*, Bean). Very low, dense shrub, ½-2 ft. high, with small lvs. about ½ in. long. A variety with the lvs. variegated with white is var. Silver Beauty, which originated in

Franklin, Mass. G.C. III. 49:10. Hybrids with *B. vulgaris* occur.

15. *Wilsonæ*, Hemsl. Low shrub with spreading branches: last year's branches reddish brown, angular, puberulous; spines 3-parted, slender,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long; lvs. oblanceolate or narrowly obovate,  $\frac{1}{4}$ –1 in. long, rounded and mucronate or acutish at the apex, rarely 3-pointed, pale green and dull above, glaucous beneath, reticulate, thickish; fls. golden yellow, in dense clusters or in very short-stalked umbels; fr. globose,  $\frac{1}{4}$  in. diam., salmon-red, usually yellow or whitish on the shady side. May; fr. in Sept. W. China. B.M. 8414. G.C. III. 42:372. Gn. 71, p. 541. G. 29:520. J.H. III. 55:425.—Very distinct handsome shrub, with small foliage, assuming a brilliant fall coloring. It has proved hardy at the Arnold Arboretum in somewhat sheltered positions.

16. *dictyophylla*, Franch. Shrub, to 6 ft. high, with slightly angular branches, usually covered with white bloom while young, reddish brown the second year: lvs. obovate to oblong-obovate,  $\frac{1}{2}$ –1 in. long, obtuse or acutish, entire or spinose-dentate, chalky white beneath: fls. solitary, pale yellow,  $\frac{1}{2}$ – $\frac{3}{4}$  in. diam., short-stalked; fr. red, ovoid,  $\frac{1}{2}$  in. long. May. S. W. China.—Very distinct, with its small foliage white beneath like the young shoots. Var. *albicaulis*, Hort., is a form with the young branchlets distinctly bloomy and the lvs. intensely white beneath. Var. *epruinosa*, Schneid. Branchlets angled, red-brown, not bloomy; lvs. light green beneath. Var. *approximata*, Rehd. (*B. approximata*, Sprague). Lvs. obovate, spinose-dentate, rarely entire, fls. smaller. B.M. 7833; the type of the species with all or nearly all lvs. entire is figured in Franchet, Plant. Delavay. 11.

17. *diaphana*, Maxim. (*B. yunnanensis*, Hutchins., not Franch.). Shrub, to 3 ft., with rather stout branches, grooved, light yellowish brown in their second year; spines 1–3-parted,  $\frac{1}{4}$ – $\frac{1}{2}$ , rarely to  $1\frac{1}{2}$  in. long; lvs. obovate to oblong-obovate, obtusish,  $\frac{3}{4}$ – $1\frac{1}{2}$  in. long, spinose-serrulate or sometimes entire, glaucous and reticulate beneath; fls. bright yellow,  $\frac{1}{2}$  in. diam., solitary, or in 2's or 3's on a common peduncle; pedicels  $\frac{3}{4}$  in. long; fr. oblong, often attenuated at the apex, scarlet, slightly bloomy, nearly  $\frac{1}{2}$  in. long. May; fr. in Sept. W. China. B.M. 8224. S.T.S. 2:109.—Remarkable for its large fr.; the lvs. turn scarlet in autumn. Hardy at the Arnold Arboretum.

18. *buxifolia*, Poir. (*B. dulcis*, Sweet). One to 3 ft.: branches brown, grooved; spines usually 3-parted, short; lvs. cuneate, obovate or elliptic,  $\frac{1}{2}$ –1 in. long; fls. solitary, on long pedicels, orange-yellow; fr. nearly globose, blackish purple. May. Chile to Strait of Magellan. B.M. 6505. S.B.F.G. II. 1:100. P.M. 10:171. L.B.C. 20:1941. H.F. 1857:122.—A very graceful, free-flowering shrub; one of the hardiest of the evergreen species; will stand the winter even N. if somewhat protected.

19. *empetrifolia*, Lam. Low, densely branched shrub, to 2 ft.: last year's branches slightly angular, brown, the young ones purplish, often bloomy; spines 1–3-parted,  $\frac{1}{4}$ – $\frac{3}{4}$  in. long; lvs. linear,  $\frac{1}{4}$ – $\frac{3}{4}$  in. long, strongly revolute at the margin, spiny pointed, bright green; fls. 1–2, on slender pedicels, about  $\frac{1}{4}$  in. long; fr. globose, bluish black, about  $\frac{1}{4}$  in. diam. May, June. Chile to Patagonia. B.R. 26:27. S.B.F.G. 4:350.—Less often cult. and not so handsome as the following hybrid, which has larger lvs. and umbellate fls.

20. *stenophylla*, Mast. (*B. Darwinii*  $\times$  *B. empetrifolia*). Height 1–3 ft., with slender, arching branches: lvs. narrow-oblong, revolute at the margins, spiny pointed,  $\frac{1}{2}$ – $1\frac{1}{4}$  in. long, dark green above; fls. 2–6, in peduncled nodding umbels. Of garden origin. May. G.C. III. 7:619. A.F. 6:325. Gn. 14, p. 46; 61, p. 305

(habit); 69, p. 318. G.W. 14, p. 593; 15, p. 103.—Handsome shrub, hardy in sheltered positions at the Arnold Arboretum.

21. *concinna*, Hook. f. Low, spreading shrub, to 3 ft.: branches of last year pale brown, angular; spines 3-parted, slender; lvs. obovate,  $\frac{1}{2}$ –1 in. long, rather thin and only half-evergreen, remotely spinose-dentate, bright green above, glaucous beneath; fls. solitary or in 2's on slender stalks,  $\frac{3}{4}$ –1 in. long, bright yellow, over  $\frac{1}{2}$  in. across; fr. red, oblong-ovoid. June. Himalayas. B.M. 4744.—One of the most graceful barberries, similar to *B. dictyophylla*, but easily distinguished by the slender-stalked fls. and half-evergreen lvs. It has proved hardy at the Arnold Arboretum in sheltered positions.

22. *verruculosa*, Hemsl. & Wilson. Dwarf, spreading shrub, to 3 ft., evergreen: branches terete, densely verruculose, with slender spines often as long as lvs.: lvs. ovate or elliptic to ovate-lanceolate, remotely spiny-toothed, dark green and lustrous above, glaucous beneath,  $\frac{1}{2}$ –1 in. long; fls. 1–2,  $\frac{1}{2}$  in. across; fr. violet-black, bloomy, ovoid  $\frac{1}{2}$  in. long, with sessile stigma. June; fr. Oct. W. China. B.M. 8454.—Very handsome with its dense dark green and lustrous foliage. Has proved hardy at the Arnold Arboretum.

23. *Gagnepainii*, Schneid. Evergreen shrub, to 6 ft.: branches yellowish gray, terete, with slender, rather long spines; lvs. narrow-lanceolate, spiny-serrate, revolute at the margin, light green beneath, indistinctly veined,  $1\frac{1}{2}$ – $3\frac{1}{2}$  in. long; fls. fascicled, 3–8,  $\frac{1}{2}$  in. across; pedicels  $\frac{1}{2}$ –1 in. long; fr. ovoid, about  $\frac{1}{2}$  in. long, bluish black, bloomy, with nearly sessile style. June; fr. Oct. W. China. G.C. III. 46:226. B.M. 8185 (as *B. acuminata*).

24. *lêvis*, Franch. Shrub, to 5 ft., evergreen: branches light yellowish gray, angled, usually with long spines; lvs. narrow-lanceolate, remotely spiny-serrate, slightly or not revolute at the margin, light green beneath, indistinctly veined, 1–2 in. long; fls. in many-fl. fascicles,  $\frac{1}{2}$  in. across; pedicels short,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long; fr. short-ovoid, about  $\frac{1}{4}$  in. long, black; stigma on a short

25. *Sargentiana*, Schneid. Evergreen shrub, to 6 ft.: branches nearly terete, grayish brown, with usually short spines: lvs. coriaceous, elliptic-oblong, with usually lanceolate, acute or acuminate, densely spiny-serrate, dark green above, light green and reticulate below,  $1\frac{1}{2}$ –4 in. long: fls. fasciated, many,  $\frac{1}{2}$  in. across; pedicels  $\frac{1}{2}$ – $\frac{3}{4}$  in. long: fr. globose-ovoid,  $\frac{1}{3}$  in. long, black, with sessile stigma. May, June; fr. Sept., Oct. W. China.—Very handsome with large dark green lvs. At the Arnold Arboretum it has proved the hardest of the evergreen barberries. See page 3566.

26. *hakeoides*, Schneid. (*B. congestiflora* var. *hakeoides*, Hook. f. *B. congestiflora*, Hort., not Gay). Shrub, to 6 ft.: last year's branches angular, grayish brown; spines small or oftener leafy, and semi-orbicular with

541. *Berberis Thunbergii*.

spiny teeth: lvs. oval to nearly orbicular, 1–2 in. long, rigid, spinose-dentate, bright green above, glaucous beneath: fls. in dense globose clusters; clusters very numerous along the branches and forming spikes toward the end which is often leafless: fr. ovoid,  $\frac{1}{4}$  in., bluish black. Chile. G.C. III. 29:295. B.M. 6770.—Very handsome with its numerous bright yellow fl.-clusters. Not hardy N.

27. *ilicifolia*, Forst. Shrub, to 8 ft.: last year's branches angular, purplish, minutely pubescent when young: lvs. obovate,  $\frac{3}{4}$ –2 in. long, dark green above, coarsely spiny-toothed: racemes 5–10-fl., shorter than the lvs. with the peduncle about 1 in. long; fls. orange-yellow. Patagonia. B.M. 4308. F.S. 3:291.—Similar to the following. Very rare in cult.; for the plants usually cult. under this name see No. 31.

28. *Darwinii*, Hook. Shrub, 1–3 ft.: branches brown, pubescent when young: lvs. cuneate, obovate, spiny-toothed and usually 3-pointed at the apex, glossy dark green above, light green and lustrous beneath,  $\frac{1}{2}$ –1 in. long: racemes 6–20-fl., longer than the lvs., with the peduncle 2–4 in. long, pendulous; fls. orange-yellow, often reddish outside; style as long as the ovary: fr. dark purple. June; fr. Aug., Sept. Chile to Patagonia. B.M. 4590. F.S. 7:663. P.F.G. 2:46. J.F. 2:111. G.M. 44:660.

29. *asiatica*, Roxbg. (*B. hypoleuca*, Lindl.). Shrub, to 10 ft.: last year's branches grayish yellow, grooved, puberulous when young; spines small: lvs. obovate to oblong, 1–3 in. long, entire or with few teeth, whitish beneath: racemes 8–25-fl., 1–2 in. long: fr. purple, with distinct style. Apr. May. Himalayas. J.H.S. 2:246.—Hardy only S.

30. *chitria*, Lindl. (*B. aristata*, Sims, not DC.). Shrub, to 6 ft.: last year's branches yellowish or reddish brown, slightly grooved or nearly terete; spines slender, to  $\frac{3}{4}$  in. long: lvs. oblong, or oblong-obovate, cuneate at the base, 1–3 in. long, spinose-serrate or entire, subcoriaceous: fls. deep yellow, often reddish, in long-peduncled panicles: fr. purplish, ovoid-oblong, with distinct style. June, July. Himalayas. B.R. 9:729. B.M. 2549 (a few-fl. form, as *B. umbellata*).—Often

confused with *B. aristata*, which is easily distinguished by its simple sessile racemes.

31. *Neubertii*, Lem. (*B. vulgaris* × *Mahonia Aquifolium*). Branches grayish brown, without spines, upright: lvs. simple, oval or ovate, or sometimes oblong, cuneate at the base, often with 1 or 2 smaller lateral lfts., spiny-toothed, dark grayish green above,  $1\frac{1}{2}$ –3 in. long: fls. in racemes. Of garden origin. I.H. 1:111. G.C. III. 9:73, 75. Var. *latifolia*, Rehd. (*B. ilicifolia*, Hort., not Forst. *B. latifolia*, Hort.). Lvs. broader, those of the shoots more rigid, with fewer and broader, more spreading spines, with broader often nearly truncate base.—Hardy in sheltered positions at the Arnold Arboretum, but not evergreen; in the S. the lvs. are persistent.

*B. actinacantha*, Mart. Evergreen shrub, to 3 ft.: spines 4–7 parted: lvs. obovate to oblong,  $\frac{1}{2}$ –1 in. long, spiny: fls. slender-stalked, in clusters. Chile. B.R. 31:55.—*B. acuminata*, Franch. Allied to *B. Gagnepainii*. Evergreen shrub: branches yellow, terete: lvs. lanceolate, 4–7 in. long, acuminate, with numerous small spiny teeth: fls. fasciated; pedicels about 1 in. long. S.W. China. J.H.F. 1900:191.—*B. acuminata*, Stapf= *B. Gagnepainii*.—*B. acuminata*, Veitch= *B. Veitchii*.—*B. atnensis*, Presl. Low, dense, deciduous shrub: branches yellowish gray, angular with numerous spines, about  $\frac{1}{2}$  in. long: lvs. oblanceolate or ovate, spinose-serrate,  $\frac{1}{2}$ –1  $\frac{1}{2}$  in. long: racemes short, 8–14-fl. Sicily, Sardinia, Corsica.—*B. aggregata*, Schneid. Allied to *B. polyantha*. Lvs. oblong-obovate, spiny-toothed,  $\frac{3}{4}$ –1 in. long; panicles short and very dense, about  $\frac{1}{2}$  in. long: fr. subglobose, salmon-red. W. China.—*B. Andreeana*, Naudin= *B. laurina*.—*B. angulosa*, Wall. Deciduous shrub, to 4 ft.: young branchlets puberulous, angular, spiny: lvs. oblong-obovate,  $\frac{1}{2}$ –1  $\frac{1}{2}$  in. long, whitish beneath, entire or sparsely spinulose: fls. solitary or few, slender-stalked: fr. red. Himalayas. B.M. 7071.—*B. Aquifolium*, Pursh= *Mahonia Aquifolium*.—*B. arguta*, Ball= *Mahonia arguta*.—*B. Belstaniana*, Hort.= *B. virescens*.—*B. Bergmannii*, Schneid. Allied to *B. Sargentiana*. Evergreen shrub, to 6 ft.: lvs. coriaceous, elliptic, indistinctly veined, 1–1  $\frac{1}{2}$  in. long; fls. fasciated, many: fr. oblong-ovoid, black, bloomy. Cent. and W. China. Var. *acanthophylla*, Schneid. Lvs. to 2 in. long, sinuately spiny. W. China. Only the variety is in cult.—*B. Bretschneideri*, Rehd. Allied to *B. koreana*. Shrub, to 8 ft.: branches terete, reddish brown with few and small spines: lvs. obovate-oblong,  $1\frac{1}{2}$ –2  $\frac{1}{2}$  in. long, setose-serrate: racemes about 1  $\frac{1}{2}$  in. long: fr. oblong, purplish. N. China. S.T.S. 2:110. Hardy N.—*B. brachypoda*, Maxim. Allied to *B. amurensis*. Shrub, to 6 ft.: lvs. elliptic-oblong, acute, pubescent on both sides,  $1\frac{1}{2}$ –3  $\frac{1}{2}$  in. long: racemes pubescent, slender, 2–3 in. long: fr. scarlet. Cent. China.—*B. candidula*, Schneid. (*B. Wallichiana* var. *candidula*, Schneid. *B. Wallichiana* var. *palida*, Boiss.). Allied to *B. verruculosa*. Evergreen prostrate shrub: branchlets glabrous, yellowish: lvs. elliptic with few spiny teeth, white beneath, about 1 in. long: fls. solitary. Cent. China. V.F. 15.—*B. Caroli*, Schneid. (*B. integrerrima* var. *stenophylla*, Maxim.). Similar to *B. Poiretii*. Shrub, to 6 ft.: lvs. oblanceolate, usually entire,  $\frac{3}{4}$ –1  $\frac{1}{2}$  in. long: racemes 8–14-fl. Mongolia. Var. *hoanghensis*, Schneid. Racemes many-fl., 1–1  $\frac{1}{2}$  in. long, pedicels  $\frac{1}{2}$  in. long: fr. subglobose, salmon-red. W. China. Only the variety is in cult.—*B. cerasina*, Schrad. Allied to *B. sinensis*, but lvs. more often toothed, racemes shorter, hardly longer than the lvs. and spines shorter, usually simple. Of unknown origin.—*B. congestiflora*, Gay. Allied to *B. hakeoides*. Lvs. oblong-ovate to orbicular, often entire: fls. in dense umbels on upright stalks  $\frac{1}{2}$ –1 in. long. Chile.—*B. cratægina*, DC. Shrub, to 5 ft.: branches brownish red, nearly terete: lvs. deciduous, oblanceolate to oblong-obovate,  $\frac{1}{2}$ –1  $\frac{1}{2}$  in. long, usually entire: racemes 6–20-fl., 1–2 in. long: fr. bluish black. Asia Minor.—The true *B. cratægina* does not seem to be in cult.—*B. crética*, Linn. Deciduous shrub, to 3 ft.: branches purplish with

542. Fruiting twig of *Berberis Thunbergii*. ( $\times \frac{1}{2}$ )

numerous spines often nearly 1 in. long: lvs. lanceolate,  $\frac{1}{4}$ – $\frac{3}{4}$  in. long, usually entire: fls. 3–7, in short umbel-like racemes. S.E. Eu. Orient.—*B. crispata*, Gay. Allied to *B. hakeoides*. Branches puberulous: lvs. thinner, ovate or oval, spiny-toothed,  $\frac{1}{2}$ –1  $\frac{1}{2}$  in. long: fls. 5–8, on slender pedicels, clustered. Chile.—*B. dealbata*, Lindl. Lvs. persistent, nearly orbicular, with few spiny teeth: racemes short, dense, nodding. Mex. B.R. 21:1750.—*B. elegans*, Hort.= *B. Lycium*.—*B. emarginata*, Willd. Possibly *B. sibirica* × *vulgaris*. Low shrub: spines 1–5-parted: lvs. obovate to obovate-oblong,  $\frac{1}{2}$ –1  $\frac{1}{4}$  in. long, setulose-dentate: racemes shorter than the lvs., upright; petals usually emarginate. Of unknown origin. G.O.H. 62.—*B. Fendleri*, Gray. Allied to *B. canadensis*. Shrub, to 5 ft.: spines 3–5-parted: lvs. obovate-lanceolate,  $\frac{3}{4}$ –1  $\frac{1}{4}$  in. long, lustrous, entire or spinulose: racemes dense, long-peduncled, pendulous. Colo. to New Mex. G.F. 1:462.—*B. Fortunei*, Lindl.= *Mahonia Fortunei*.

—*B. Fremontii*, Torr.=*Mahonia Fremontii*.—*B. glauca*, Benth., not Kunth= *B. Jamiesonii*.—*B. gracilis*, Hartw.=*Mahonia gracilis*.—*B. haematocarpa*, Wooton= *Mahonia haematocarpa*.—*B. heterophylla*, Juss. Allied to *B. ilicifolia*. Branches glabrous, yellowish brown; spines 3-5-parted: lvs. persistent, obovate to oblong,  $\frac{1}{2}$ -1  $\frac{1}{2}$  in. long, entire, or with 2-4 spiny teeth: fls. solitary: fr. purplish black. Straits of Magellan. H.E. 1:14.—*B. heterophylla*, Zabel= *Mahonia heterophylla*.—*B. Hookeri*, Lem. (*B. Jamiesonii*, Hort., not Lindl. *B. Wallichiana*, Hook., not DC.). Allied to *B. Sargentiana*. Branchlets angular, stout, pale yellowish brown: lvs. elliptic-oblong to oblong-lanceolate, sinuately spiny-toothed, 1-2 in. long: fls. 3-6; pedicels slender: fr. oblong, large, with 4-8 seeds. Origin uncertain; probably Himalayas. I.H. 6:207. B.M. 4656.—*B. Hutchinsiana*, Rehd.=*Mahonia arguta*.—*B. Jamiesonii*, Lindl. (*B. glauca*, Benth., not Kunth). Evergreen shrub: branches terete, brownish red: lvs. oblong, 2-3 in. long, entire or with few teeth, lustrous, pale green beneath: fls. in close panicles; pedicels  $\frac{1}{2}$  in. long. Peru.—Often confused with *B. Hookeri* and *B. Verschaffeltii*.—*B. japonica*, Spreng.=*Mahonia japonica*.—*B. Knightii*, Hort.=*B. Wallichiana* var. *latifolia*.—*B. laurina* Billbg. (*B. Andreae*, Naudin). Allied to *B. buxifolia*. Shrub, to 5 ft.: branches glabrous, terete; spines to 1 in. long: lvs. oblanceolate, 1-3 in. long, entire, pale beneath: racemes pendulous, to 5 in. long: fr. black, bloomy. S. Brazil. R.H. 1899, p. 9.—*B. lariflora*, Schrad. Allied to *B. amurensis*. Lvs. oval to oval-elliptic, obtuse, serration less dense, grayish green beneath: racemes pendulous, 2-3  $\frac{1}{2}$  in. long. Of unknown origin.—*B. Liechtensteinii*, Schneid. Deciduous shrub, to 5 ft.: branches slightly angled, purplish with strong spines: lvs. ovate to lanceolate, sinuately spiny, light green beneath,  $\frac{1}{2}$ -2  $\frac{1}{2}$  in. long: fls. in racemes 1-1  $\frac{1}{2}$  in. long: fr. globose, red, with 2 seeds. W. China.—*B. lucensis*, Benth. Lvs. persistent, oblong-obovate, entire or sometimes with a few spiny teeth, lustrous: fls. small in peduncled, loose racemes. Peru. F.S. 6, p. 69.—*B. lucida*, Schrad. Allied to *B. vulgaris*. Lvs. elliptic to elliptic-oblong, dark green and lustrous above, obtuse, remotely and finely serrate: racemes spreading, about 2 in. long: fr. red. Of unknown origin; possibly variety of *B. vulgaris*.—*B. Lycium*, Royle (*B. ruscifolia*, Hort., not Lam. *B. elegans*, Hort.). Shrub, to 6 ft. or more: branches terete, yellowish gray: lvs. sub-persistent, obovate-lanceolate,  $\frac{3}{4}$ -2 in. long, entire or spinulose: racemes sessile, longer than the lvs., drooping: fr. violet. Himalayas. B.M. 7075.—*B. macrophylla*, Hort.=*B. Wallichiana* var. *latifolia*.—*B. macracantha*, Schrad. Possibly *B. aristata*  $\times$  *vulgaris*. Branches yellowish gray: lvs. elliptic, acutish, remotely spiny-toothed, 1-2 in. long: racemes nodding, 1  $\frac{1}{2}$ -2  $\frac{1}{2}$  in. long: fr. red. Of unknown origin.—*B. microphylla* var. *serrata*, Hort.=*B. serrata*.—*B. Mouillacana*, Schneid. Deciduous shrub, to 10 ft.: branches grooved, purplish, with simple spines: lvs. obovate-lanceolate, obtuse, usually entire, light green beneath,  $\frac{1}{2}$ -2 in. long: fls. in racemes, to 1  $\frac{1}{2}$  in. long: fr. scarlet, with 2 seeds. W. China.—*B. oblonga*, Schneid. (*B. heteropoda* var. *oblonga*, Regel.). Allied to *B. heteropoda*. Branches angular: lvs. obovate: racemes 10-20-fld., usually compound near the base; ovary with 2 sessile ovules: fr. oblong. Turkestan.—*B. nepalensis*, Spreng.=*Mahonia nepalensis*.—*B. nervosa*, Pursh= *Mahonia nervosa*.—*B. pallida*, Benth.=*Mahonia pallida*.—*B. parviflora*, Lindl.=*B. ruscifolia*.—*B. parvifolia*, Sprague. Allied to *B. Wilsonae*. Low shrub: lvs. half-evergreen, oblanceolate, entire or occasionally spiny-toothed, glabrous and reticulate beneath: fls. fascicled, 3-6: fr. globose, terra-cotta color. W. China.—*B. pinnata*, Lag.=*Mahonia pinnata*.—*B. Pratii*, Schneid. Allied to *B. polyantha*. Shrub, to 10 ft.: lvs. oblong-obovate, entire or with few spiny teeth, reticulate, thinner: panicles narrow, to 6 in. long: fr. globose, salmon-red. W. China. Var. *recurvata*, Schneid. Raceme narrow, spike-like: fr. on reflexed pedicels. W. China.—*B. pruinosa*, Franch. Evergreen shrub: branches brownish yellow, nearly terete; spines to 1 in. long: lvs. ovate-oblong,  $\frac{3}{4}$ -2 in. long, strongly spiny-toothed, whitish beneath: fls. 8-25, fascicled, rarely in a peduncled umbel: fr. bluish black. S.W. China.—*B. Rehderiana*, Schneid. Allied to *B. koreana*, but much smaller in every part, branches reddish brown, slightly angled; spines 3-5-parted: lvs. obovate to oblong, spinose-serrate,  $\frac{3}{4}$ -1  $\frac{1}{2}$  in. long: fls. 8-15, in a peduncled raceme: fr. sub-globose, bright red. Origin unknown.—Hardy, graceful shrub; the fr. remains unchanged until the following spring.—*B. repens*, Lindl.=*Mahonia repens*.—*B. rotundifolia*, Hort.=*Mahonia repens* var. *rotundifolia*.—*B. ruscifolia*, Lam. (*B. parviflora*, Lindl.). Allied to *B. buxifolia*. Branches terete, yellowish gray: lvs. oblong, entire or with a few coarse teeth,  $\frac{1}{2}$ -1  $\frac{1}{2}$  in. long: fls. in 4-5-fld. peduncled raceme: fr. bluish black. Argentine. J.H.S. 2:243.—*B. ruscifolia*, Hort.=*B. Lycium*.—*B. sanguinea*, Franch. Allied to *B. Gagnepainii*. Lvs. narrow-lanceolate,  $\frac{3}{4}$ -2 in. long, spinose-serrate, pale beneath: fls. with red sepals, in fascicles of 2-4; pedicels  $\frac{3}{4}$  in. long: fr. bluish black. W. China. V.F. 16.—*B. serotina*, Lange. Allied to *B. sinensis*. Lvs. light green, oblanceolate, usually entire: racemes short and dense. Origin unknown.—*B. serrata*, Koehne (*B. microphylla* var. *serrata*, Hort.). Low, deciduous shrub: branches grooved, reddish or yellowish brown: lvs. oblong-lanceolate,  $\frac{1}{2}$ -1 in. long, spinulose-serrate: racemes dense, short. Origin unknown.—*B. sibirica*, Pall. Deciduous shrub: branches angular, yellowish brown; spines 3-9-parted: lvs. obovate, remotely toothed: fls. solitary or 2, short-pedicelled: fr. red. Siberia. B.K. 6:487.—*B. Silve-Taroucana*, Schneid. Deciduous shrub, to 10 ft.: branches grooved, brown; spines small or wanting: lvs. oblong-lanceolate or obovate-oblong, obtuse, entire or with few small teeth, pruinose beneath,  $\frac{1}{2}$ -2 in. long: racemes 1-2  $\frac{1}{2}$  in. long: pedicels  $\frac{1}{2}$ - $\frac{3}{4}$  in. long: fr. globose-ovoid, scarlet, with 1-2 seeds. W. China.—*B. subcaulata*, Schneid. Deciduous shrub: branches strongly angulate: lvs. oblanceolate,  $\frac{1}{2}$ -1 in. long, acute, rarely 3-pointed at the apex, whitish beneath: fls. in very short, 6-8-fld. racemes or rarely fascicled, nodding: fr. globose, red. W. China.—*B. tenuifolia*, Lindl.=*Mahonia tenuifolia*.—*B. thibetica*, Schneid. Deciduous shrub: branches angular, purplish, bloomy: lvs. obovate-lanceolate,  $\frac{1}{2}$ -1 in. long, rounded or acutish, mucronulate, entire, whitish beneath: fls. in

1-5-fld. fascicles; pedicels about  $\frac{1}{2}$  in. long. W. China.—*B. Tischleri*, Schneid. Allied to *B. diaphana*. Shrub, to 8 ft.: branches angled, gray, spiny: lvs. obovate to oblong, obtuse, spinulose-serate, pruinose beneath,  $\frac{1}{2}$ -1  $\frac{1}{2}$  in.: racemes 4-15-fld.; pedicels  $\frac{1}{2}$ -1 in. long: fr. oblong, with a distinct style, pale red, pruinose. W. China.—*B. toluacensis*, Hort.=*Mahonia heterophylla*.—*B. triacanthophora*, Fedde. Allied to *B. Gagnepainii*: evergreen shrub, to 5 ft.: branches terete, brown: lvs. linear-lanceolate with 2 to 5 spiny teeth on each side or entire, glaucous beneath, 1-2 in.: fls. 2-5, slender-stalked: fr. black, ovoid, with sessile style. Cent. China.—*B. trifoliolata*, Hartw.=*Mahonia trifoliolata*.—*B. trifoliolata*, Moric.=*Mahonia trifoliolata*.—*B. trifurca*, Forbes= *Mahonia japonica* var. *trifurca*.—*B. umbellata*, Wall. Deciduous shrub: branches angular, gray: lvs. oblanceolate, usually entire, rarely sparsely serrulate: racemes long-peduncled, usually umbel-like, sometimes elongated. Himalayas. B.R. 30:44.—*B. Veltchii*, Schneid. Allied to *B. levis*. Evergreen shrub: lvs. narrow-lanceolate, acuminate, sinuately toothed with long and strong spines, 2-4 in. long: fls. 5-8, slender-stalked: fr. ovoid, bluish black. Cent. China.—*B. Verschaffeltii*, Schneid. (*B. Jamesonii*, Lem., not Lindl.). Evergreen shrub: lvs. oblong, 2-3 in. long, sparingly spiny-toothed: fls. orange in drooping panicles. Ecuador. I.H. 6:201.—*B. viridescens*, Hook. Deciduous shrub, 2-5 ft.: branches yellowish red or red, lustrous, terete: lvs. obovate,  $\frac{1}{2}$ -1  $\frac{1}{2}$  in. long, spiny-toothed or entire, light green, whitish beneath: fls. pale yellow, few, fascicled or in peduncled umbel-like racemes: fr. purple, bloomy. Himalayas. B.M. 7116.—Graceful shrub. Hardy at the Arnold Arboretum.—*B. Wallichiana*, DC. Allied to *B. Sargentiana*. Evergreen shrub, to 10 ft.: branches grooved, spiny: lvs. elliptic to lanceolate, spiny-serrate with numerous small teeth, lustrous above, light green beneath, reticulate, 2-4 in. long: fls. 10-20; pedicels about  $\frac{1}{2}$  in. long: fr. ovoid, black, with usually 1 long-stalked seed. Himalayas. P.F.G. 1, p. 79. Var. *latifolia*, Hook. f. & Thoms. (*B. Knightii*, Hort., not Koch. *B. macrophylla*, Hort.). Branchlets less grooved: lvs. broader, thinner.—*B. Wallichiana*, Hook.=*B. Hookeri*.—*B. yunnanensis*, Franch. Allied to *B. diaphana*. Branches grooved, gray: lvs. obovate-oblong, 1 in. long, entire, glaucous beneath: fls. 3-5, fascicled. S.W. China.—Has been confused with *B. diaphana*. See page 3566.

ALFRED REHDER.

**BERCHÈMIA** (derivation uncertain). *Rhamnaceae*. Ornamental woody climbers, grown chiefly for their bright green graceful foliage.

Deciduous twining shrubs: lvs. alternate, entire or nearly so, petioled, with conspicuous numerous parallel veins: fls. perfect; sepals, petals and stamens 5; calyx-tube shallow; ovary free, 2-celled, with a 2-parted style: drupe oblong to cylindric with a 2-celled stone.—About 12 species in S. and Cent. Asia, N. Amer. and E. Afr.

These slender climbing shrubs have inconspicuous greenish white flowers in terminal panicles followed by berry-like, small, usually oblong, black or red fruits. The cultivated species are not quite hardy North and prefer sunny positions; they grow in almost any soil and are useful for trellis-work, when no dense shade is desired. Propagation is by seeds and by root-cuttings in spring under glass; also by layering the young shoots and by cuttings of mature wood in fall under glass.

*scandens*, Koch (*B. volubilis*, DC.). SUPPLE-JACK. Ten to 15 ft.: lvs. ovate or oblong-ovate, acuminate, often undulate, 1-3 in. long, with 9-12 pairs of lateral veins: fls. greenish white in small terminal panicles: fr. bluish black,  $\frac{1}{4}$ - $\frac{1}{2}$  in. long. June. Southern states. B.B. 2:404. S.O.B. 3:153.

*racemosa*, Sieb. & Zucc. Closely allied to the former. Lvs. cordate, ovate, 1-2  $\frac{1}{2}$  in. long, with 6-8 pairs of veins: fls. greenish in large terminal panicles: fr. first red, becoming black at length. July. Japan, China.—Hardier than the former, not high-climbing; attractive in late summer, with its red frs.

*B. Giraldiana*, Schneid. Allied to *B. racemosa*. Lvs. ovate-oblong, 1-3 in. long, grayish white beneath, with 9-11 pairs of veins; petioles  $\frac{3}{4}$  in. long. W. China.—*B. lineata*, DC. Allied to *B. scandens*. Lvs. smaller, oblong-ovate, obtuse, with about 9 pairs of veins, grayish white beneath. N. and W. China.

ALFRED REHDER.

**BERGAMOT**. Name applied to various aromatic plants, particularly to members of the *Labiatae*, as menthas and monardas. The bergamot essence of commerce is made from a citrous fruit. See *Citrus*.

**BERGEROCÁCTUS** (named for Alwin Berger, Curator of the Hanbury Garden, at La Mortola, Italy). *Cactaceae*. A low, much-branched, day-blooming cactus with cylindrical, low-ribbed sts.: areoles close together,

bearing many yellow spines: corolla short, funnel-shaped, greenish yellow: fr. globose, densely spiny.—A single species known.

**Émoryi**, Brit. & Rose (*Cereus Émoryi*, Engelm.). Prostrate or ascending, 6–10 in. high, 1–2 in. diam., often forming thick masses 10–20 ft. in diam.: fls. 1–2 in. broad: fr. 1–1½ in. diam. On mainland and isls. of S. Calif., and N. Low. Calif.—This species, native of Calif., can easily be grown in the open in the southern part of that state. It forms large masses and care must be taken that it does not preempt more than its share of the garden. The species has long been in the trade, but it does not do well in the greenhouse, and it is hardly to be recommended for the small collection. Its slender sts., covered with striking yellow spines, are very unlike any of our other cereus-like plants.

J. N. ROSE.

**BERMUDA GRASS:** *Cynodon dactylon*.

**BÉRRIA** (after Dr. Andrew Berry, a Madras botanist). Syn., *Berrya*, DC., not Klein. *Tiliaceæ*. A timber tree of India, which has been sparingly introduced into this country. One species.

**Ammonilla**, Roxbg. High tree: lvs. entire, heart-shaped, long-petioled, smooth, 5–7-nerved, alternate: fls. in racemes, small, white, very numerous: fr. a 3-celled caps. with 6 wings, the 3–12 seeds with stiff hairs, which readily penetrate the skin and produce a painful itching.—Grows abundantly in British India, Ceylon, the Malay Archipelago, and the Philippines. The wood is smooth-grained, yellow, with dark red heart; used for house-building, agricultural implements, oil-casks, boats, and the like. Exported as “trincomalee wood.”

G. T. HASTINGS.

**BERSÂMA** (Abyssinian name). *Sapindaceæ*. Trop. and S. African trees and shrubs, of perhaps a half-dozen species, probably not cult. Lvs. alternate, odd-pinnate; lfts. entire or serrate: fls. silky, white, of 5 sepals and 5 unequal clawed petals. *B. usambarensis*, Guerke, a recently described species from German E. Afr., has been discussed in horticultural journals: tree, 50 ft.: lvs. more than 2 ft. long, with winged rachis, the lfts. oblong-lanceolate and somewhat cut, prickly-margined.

**BERTHOLLÈTIA** (after Louis Claude Berthollet, French chemist). *Myrtaceæ*. BRAZIL-NUT. BUTTER-NUT. PARA-NUT. CREAM-NUT. NIGGER-TOE. Large

543. *Bertholletia excelsa*. Cross-section of husks, showing Brazil-nuts. ( $\times \frac{1}{4}$ )

trees: lvs. alternate, bright green, leathery, about 2 ft. long, 6 in. broad: fls. cream-colored; calyx parts united and tearing into 2 parts when the flower opens; petals 6; stamens many, united into a hood-shaped mass, the upper ones sterile: fr. round, about 6 in. diam., with a hard shell containing 18–24 3-sided nuts (Fig. 543).—Species several, all furnishing Brazil

nuts and usually

described as *B. excelsa*. The common trade name is Castanea, the name of the genus including the chestnuts. **excelsa**, Humb. & Bonpl. Fig. 543. A tree 100–150 ft. with a smooth trunk 3–4 ft. in diam.: branches near the top.—It forms large forests on the banks of the Amazon and Rio Negro. The natives gather the nuts in large quantities, chopping the fr. open. They are

exported in large quantities, chiefly from Para. An oil is expressed from the kernels, and the bark is used at Para for caulking ships. The tree is of little value for decorative purposes, and, is too tender for growth anywhere in the U. S.

G. T. HASTINGS.

**BERTOLONIA** (after A. Bertolini, Italian botanist). *Meistomaceæ*. Excellent greenhouse foliage plants from Brazil.

Always dwarf, and sometimes creeping; the garden forms with membranaceous, 5–11-nerved lvs. 5–8 in.

544. *Bertolonia marmorata*.

long, and purple beneath: fls. white, purple or rose-colored, 5-petaled, in scorpioid racemes or spikes. There are only 9 species, 5 of which were distinguished when the last edition was issued. (A. Coigneaux, in DC. Mon. Phan., Vol. VII.) Some earlier botanists do not separate certain allied genera which usually cannot be distinguished by habit alone. The surest character is the inflated and 3-angled or 3-winged calyx of Bertolonia. In Bertolonia, fl.-parts are in 5's, but the ovary is 3-celled. *Gravesia* has a 5-celled ovary, and *Sonerila* is trimerous. In Bertolonia, the connective of the anthers has no appendage; in *Salpinga* there is a spur below and behind the connective; in *Monolena* there is a spur in front, and the calyx is not hairy.

Bertolonias are essentially fanciers' plants. It is somewhat difficult to bring out their true characteristics under ordinary stove treatment, as they require a more humid atmosphere than can usually be maintained, even in a small house. The additional shelter of a small frame should be provided, where the atmospheric conditions will be much more easily regulated. A plentiful supply of water at the roots is necessary; syringing or sprinkling overhead is not advisable.—The most convenient method of propagation is by cuttings, which strike readily, in a moderately close propagating-case filled with sharp, clean sand. The pots should be thoroughly clean and drained, and the compost open and porous. They may also be grown from seed. They thrive in dense shade. Old plants are not so brilliant as young ones. (Wm. Scott.)

Bertolonias and their allies furnish an excellent example of Van Houtte's triumphs in hybridization. The two species described below have probably been important factors in the plant-breeding, and *Gravesia guttata* even more so. *Gravesia* is a Madagascar plant, and has, perhaps, been crossed with the Brazilian bertolonias. Unfortunately, the pictures in Flore des Serres show no flowers, and the pedigree is not given. The bertonerilas figured and described in I.H. 43, pp. 188 and 189, with colored plates 64 and 68, are presumably hybrids between Bertolonia and Sonerila. Excepting *B. maculata* and *B. marmorata*, the following are hybrids:

*A. Veins not lined on both sides with a colored band.*

**marmorata**, Naudin. Fig. 544. St. less densely hairy than *B. maculata*: lvs. more narrowly ovate, ovate-

oblong, acute, sparsely hairy, streaked with white along the veins: calyx sparsely hairy, not glandular; petals somewhat blunter, dilute purple. R.H. 1848:381 (as *Eriocnema marmorata*, Naudin). F.S. 7:750 (as *B. maculata* var. *marmorata*, Planch.). Coigneaux recognizes 2 varieties, var. *genuina*, with lvs. green above, and banded with white along the veins; var. *ænea*, (*E. ænea* and *B. ænea*, Naudin), with lvs. dark green with a coppery cast, but not spotted or only slightly so.

**Mirándæi**, Van Houtte. Spots red on the lower lvs. and white on the upper or younger ones: lvs. purple beneath. F.S. 21:2235 (1875).

AA. *Veins lined on both sides with a white or colored band.*

B. *Bands and spots magenta or purple.*

**maculata**, DC. St. short, decumbent, rooting at the base, densely clothed with rusty hairs: lvs. long-petioled, cordate, broadly ovate, obtuse, hispid above and at margins, dark velvety green above, often spotted: calyx densely clothed with glandular hairs; petals obovate, somewhat acute, rose-colored. B.M. 4551.

**Houtteana**, Van Houtte (*B. Van Houttei*, Hort.). Lvs. purple beneath. F.S. 20:2120.—This was a sensational plant of 1875, and Van Houtte refused \$2,000 for his stock of it.

BB. *Bands and spots silvery white.*

c. *Spots very distinct.*

**Hrubyana**, Van Houtte. This has bars of white connecting the veins. The under side of the lvs. seems to be green instead of purple, at least toward the tip. F.S. 23:2381.

**Rodeckiana**, Van Houtte. Distinguished from the above and all others of this group by the abundance of dark red color on the upper surface of the lvs.: veins of the under side prominent and green. F.S. 23:2332.

cc. *Spots very faint.*

**Legrelleana**, Van Houtte (*B. Legrelle*, Hort.). There are a few longitudinal bars, but they do not connect the veins. Referred to *Gravesia guttata* by Coigneaux. F.S. 23:2407.

Other trade names are *B. guttata*, Hook. f.—*Gravesia guttata*.—*B. margaritacea*, Hort. Bull.—*Salpinga margaritacea*.—*B. primulaeflora*, Hort.—*Monoleuca primulaeflora*.—*B. pubescens*, Hort., with long white hairs, and a chocolate band down the center. Ecuador.—*B. punctatissima*, Hort.—*B. superbissima*, Hort. (*B. superba*?, Hort.), with rose-colored spots, which are larger and brighter near the margin. F.M. 151 (1875).—Probably a variety of *Gravesia guttata*.

WILHELM MILLER.

N. TAYLOR.†

**BERTONERILA**. A class of handsome foliage plants, presumably hybrids between *Bertolonia* and *Sonerila*. *Bertonerila* is a combination of the names *Bertolonia* and *Sonerila*. I.H. Vol. 43 (1896), pp. 188–190. For culture, see *Bertolonia*.—Rare in this country, perhaps not in cult. outside of a few botanic gardens. Some of the best-known forms are: Madame Cahuzae, Madame de Brezetz and Madame Treyeran.

**BESCHORNËRIA** (after H. Beschorner, German botanist). *Amarylhidaceæ*. Succulent desert plants, allied to Bravao, Fourcroya and Doryanthes, planted far south and in California, and sometimes seen in collections under glass in the North.

Leaves in a rosette, glaucous, roughish at the margins, not so thick, firm or fleshy as in *Agave* (which has a strong end-spine and horny marginal prickles): root-stock short, tuberous: fls. accompanied by showy colored bracts. In *Beschorneria*, the perianth is usually reddish green, funnelliform but with a very short tube and with long, oblanceolate segms.; in *Doryanthes* the perianth is bright red, the segms. long, narrowly falcate; in Bravao the perianth is red or white, the tube curved, sub-cylindrical, and the segms. short. From Fourcroya, to which the genus is closely related, *Beschorneria* is

distinguished by its tubular-shaped perianth, long and narrow segms., thin and slender filaments, which are only slightly thickened below the middle. The perianth of Fourcroya is campanulate, with spreading, ovoid or elliptic segms., and short thickened filaments; the fourcroyas are larger plants, and without large showy bracts, and often produce bulbils, which *Beschorneria* never does.

The species are very closely allied, and difficult to distinguish. The following are the only kinds well known, and they are all from Mexico. If in good condition they bloom every year in warm countries from suckers of the previous year, but in the North they are likely to bloom only at long irregular intervals. The species succeed best when treated similarly to agaves, with the exception of the soil, which may be made richer by the addition of crushed bone and a little vegetable-mold. All of the species need greenhouse protection in the northern states. They are hardy in the warmest parts of the British Islands. Useful for bedding as striking foliage subjects.

**tubiflora**, Kunth. No st. or trunk: lvs. 12 or more, 1½–2 ft. long, 1 in. broad, linear, long-acuminate, roughish on both surfaces, tufted, more or less recurved, thickened and triangular at base, minutely striated, glaucous-green: scape 4 ft., terminating in an erect raceme; fls. drooping, 2–4 together, the perianth divided to the top of the ovary, brownish green. B.M. 4642.—The oldest and best-known species.

**Tonéllii**, Jacobi (*B. Tonelliana*, Jacobi). Allied to *B. tubiflora*, but with looser habit, much broader foliage, bright red-purple scape and a colored panicle with drooping branches, longer purple and red fls. with more acute segms.: st. or trunk very short: lvs. very glaucous, roughish beneath and on the margins, 15–20 in number, 1–1½ ft. long, 2–2½ in. broad, short-acuminate, and contracted below the middle into a flat thick petiole 1 in. broad. B.M. 6091.

**Dekosteriana**, C. Koch (*B. Decosteriana*, Baker). Lvs. 15–20 or more, 2–2½ ft. long, 2–2½ in. broad, oblanceolate, long-acuminate, very gradually tapering both ways from the middle, 1–1¼ in. broad above the base, which is very thick: fls. in a deltoid panicle, green, 1½ in. long, cut nearly to base, the ovary protruding. B.M. 6768.

**bracteata**, Jacobi. Stemless: lvs. 20–30, 1½–2 ft. long, 2 in. broad, short-acuminate, texture thin but firm, contracted to less than 1 in. wide above the dilated base, glaucous green, scarious or dry on the margin: scape 4–5 ft., the panicle reddish brown; fls. 1½ in. long, segms. free but connivant, green, changing to yellowish red. B.M. 6641.

**yuccoides**, Hook. f. St. none, or apparently present by shedding of older lvs. in the rosette: lvs. about 20, 1–1½ ft. long, 2 in. broad, lanceolate, short-acuminate, narrowed to ½ in. above the base, glaucous green: scape 3–4 ft., with fls. on drooping red branches in the panicle; fls. about 3 in. long, dark green, tinged yellow. B.M. 5203. G.C. III. 46:8, 309, 313.—The lvs. are broader than in *A. tubiflora*, shorter acuminate, and more boldly narrowed below the middle.

**Wrightii**, Hook. f. Allied to *B. Dekosteriana*, but fls. pubescent: st. or trunk 18 in.: lvs. about 50, densely crowded, spreading or recurved, ensiform, 4–5 ft. long by 2 in. at the middle, the tip narrowed to a long brown stiff point, the base dilated and very thick and bi-convex, the margins very narrowly scarious, denticulate: panicle pyramidal, 8 ft.; fls. fascicled, nodding, greenish, pubescent. B.M. 7779.

**pubescens**, Berger. Smaller: lvs. 2 ft. long by 2 in. broad, glaucous, rather stiff and fleshy along the midrib, nearly smooth underneath, rough only near tip, margins finely and deeply denticulate: panicle 4–5 ft., rather slender, the scape bright red; fls. fascicled in axils of

ovate bracts, green, fading to yellow, pubescent. G.C. III. 40:350.

*B. argyrophylla*, Hort.=*B. Dekosteriana*.—*B. californica* is a nomen nudum.—*B. superba*, Hort. and *B. viridiflora*, Hort.=*B. yuccoides*.

G. W. OLIVER.  
L. H. B.†

545. *Bessera elegans*.

**BESLÈRIA**  
(after Basil Besler, Nuremberg apothecary, and reputed author of the superb Hortus Eystettensis, 1613).

*Gesneriaceæ*. A genus of 50 species of Trop. American plants, mostly subshrubs, with somewhat 4-angled sts., large, membranaceous, opposite, petiolate lvs. prominently veined beneath, and yellow, white or purple fls.: calyx campanulate, at length globose, shortly 5-toothed; corolla tubular. *B. Imray* is herbaceous, with serrate lvs. and yellow axillary fls. B.M. 6341. Prop. by cuttings over bottom heat. None is known to be offered in Amer.

*lutea*, Linn. St. 6–10 ft., glabrous or nearly so; lvs. elliptic or elliptic-oblong; calyx about half as long as the yellow slightly gibbous corolla. Trop. Amer.

N. TAYLOR.†

**BÉSSERA** (after Dr. Besser, professor of botany at Brody). *Liliaceæ*. MEXICAN CORAL DROPS. An exceedingly pretty summer-flowering bulbous squill-like plant.

Umbels pendulous; fls. vermilion outside, with a white corona or cup within, and long, purple stamens; perianth cup-shaped, the tube shorter than the oblong-lanceolate segms.; stamens 6.—A monotypic genus allied to *Androstephium*. Culture simple. Bulbs planted out, and lifted when ripe. May be prop. by offsets.

*élégans*, Schult. f. Fig. 545. Bulb globular, 1 in. thick, tunicated; lvs. 2–3, about 10–12 in., or even 2 ft., long; scape 1–2 ft. long, hollow, fragile; umbels 4–10-fld.; pedicels 1–1½ in. long; perianth 9–10 lines long, keeled on the back, variously marked with white within, but usually with vermilion margins and center-band; fls. borne through two months of late summer and early autumn. G.F. 4:125 (adapted in Fig. 545). Gn. 25:42. B.R. 1546 (as *Phorium fistulosum*); 25:34. F.S. 4:424 (as *B. miniatum*).—Strong bulbs sometimes throw up 6–10 scapes, with 12–20-fld. umbels.

WILHELM MILLER.

**BÈTA** (ancient name). *Chenopodiaceæ*. BEET-ROOT. BEET. Annuals in cultivation, or biennials by the wintering of the roots, grown for the thick edible roots, edible leaves, and ornamental foliage.

Glabrous, mostly thick-rooted herbs, with alternate, entire or sinuate lvs.: fls. perfect, bracted; perianth urn-shaped, 5-lobed, adhering at base to the ovary, becoming hardened in fr.;

stamens 5 on a fleshy ring or disk; ovary partly inferior, in fr. covered by the withered and corky remains of the perianth; the fls. usually stand 2 or more together and cohere into a “seed” or “ball” that is more than 1-seeded.—The species of Beta are much confused, but probably all of them can be referred to a half-dozen species. Eu., N. Afr., Asia.

*vulgàris*, Linn. (*B. maritima*, Linn.). The supposed source of the cult. beets and foliage beets. Probably a development from the perennial beet of the coasts in parts of Eu., a much-branched decumbent plant (Fig. 546), with thick, long and hard (not really fleshy) perennial roots. In cult. forms, the plant is erect in fls. and fr., with greenish clustered fls., and ovate-oblong, smooth, more or less thick and wavy-margined lvs. There are 3 main races of the cult. beet-plant:

Var. *cràssa*, Alef. BEET-ROOT. BEET of American gardens and fields, characterized by its thickened root of many forms, some of which are developed for their sugar-producing qualities. See *Beet*.

Var. *crúenta*, Alef. (*B. horténsis* and *B. rubra*, Hort.). RED and VICTORIA foliage beets. Root not highly developed: lvs. large and showy, red or green, with yellow ribs. Var. *metállica* is a form of this. In many brilliant forms, often used in bedding and for strong color effects.

Var. *Cícila*, Moq. (*B. Cícila*, Linn. *B. brasiliénsis* and *B. chilénsis*, Hort.). LEAF-BEET. SICILIAN BEET. SEA-KALE BEET. SPINACH BEET. CHILIAN BEET. ROMAN KALE. POIREI. Root small and branched, not thick or fleshy: lvs. very large, thick-ribbed, green, yellow-green, reddish green or even red, often with very wide and thick petioles.—Used as a pot-herb. Differs widely in the coloration of the lf.-ribs, and shape and development of lf.-blade. One form of it is *Chard* (which see).  
L. H. B.

**BETEL**, or **BETLE**. The leaf of *Piper Belle*, a kind of pepper used in wrapping the pellets of betel-nut and lime which are commonly chewed in the Orient. The pellets are hot, acrid, aromatic, astringent. They redden the saliva and blacken the teeth, and eventually corrode them. The betel-nut is the fruit of *Areca Catechu*, a palm. See pp. 16 and 24.

**BETÓNICA** and **BETONY**: *Stachys*.

**BÉTULA** (ancient Latin name). *Betulaceæ*. BIRCH. Ornamental deciduous woody plants grown chiefly for their bright green handsome foliage. Page 3566.

Trees or shrubs: winter-buds usually conspicuous, sessile, with several imbricate scales: lvs. alternate, petioled, serrate or crenate; fls. monœcious, apetalous, in catkins, staminate formed in autumn and remaining naked during the winter, every scale bearing 3 fls., each with a minute 4-toothed calyx and with 2 stamens divided at the apex; pistillate catkins oblong or cylindrical, bearing 3 naked ovaries in the axil of every scale

546. *Beta*. The wild perennial form of the beet plant as it grows on the coasts of England.

consisting of 3 connate bracts: fr. a minute nut, often erroneously called seed, with membranous wings, dropping at maturity with the 3-pointed scales from the slender rachis of the strobile.—About 35 species in N. Amer., Eu., N. and Cent. Asia, especially in the northern regions. No tree goes farther north than the birch, in N. Amer. *B. papyrifera* reaches 66° north latitude, and in Eu. *B. pubescens* goes to the N. Cape, and is still a forest tree at 70°. Monogr. by Regel: Monographische Bearbeitung der Betulaceae (1861); and in De Candolle, *Prodromus*, 16, 2, p. 162 (1869); and by Winkler in Engler's *Pflanzenreich: Betulaceae*, p. 56, quoted below as W. B.

The birches are often conspicuous on account of their colored bark, and slender usually pendulous staminate catkins before the leaves and much smaller pistillate catkins, followed by subglobose to cylindric strobiles. The hard and tough wood is often used in the manufacture of furniture and of many small articles, in making charcoal, and for fuel; from the bark, boxes, baskets, and many small articles are made; also canoes from that of the *B. papyrifera*; in Russia and Siberia it is used in tanning leather. The sap of some species is used as a beverage. The birches are very ornamental park trees, hardy, except two or three Himalayan species, and especially valuable for colder climates. They are essentially northern trees and are short-lived in warmer regions, particularly mountain species like *B. lutea*, while *B. nigra* and *B. lenta* are better suited for a warmer climate than most other species. Their foliage is rarely attacked by insects, and turns to a bright or orange-yellow in fall. Their graceful habit, the slender, often pendulous branches, and the picturesque trunks make them conspicuous features of the landscape. Especially remarkable are those with white bark, as *B. papyrifera*, *B. populifolia*, *B. pendula*, *B. Ermanii*, and also *B. Maximowiczii* with yellow bark.

Most birches prefer moist, sandy and loamy soil; but some, as *B. pendula* and *B. populifolia*, grow as satisfactorily in dry localities and poor soil as in swamps and bogs, and they are especially valuable in replanting deserted grounds as nurses for other trees; both are comparatively short-lived trees.

Propagation is readily accomplished by seeds, gathered at maturity and sown in fall, or usually kept dry during the winter, or stratified; but *B. nigra*, which ripens its fruits in June, must be sown at once, and by fall the seedlings will be several inches high. The seeds should be sown in sandy soil, rather thick, as the percentage of perfect seeds is not very large, slightly or not at all covered, but pressed firmly into the ground and kept moist and shady. The seedlings must be transplanted when one year old. Rarer species and varieties are grafted, usually on *B. lenta*, *B. papyrifera*, *B. nigra* or *B. pendula*. Cleft or tongue-grafting in early spring, on potted stock in the greenhouse, is the best method. Budding in summer is also sometimes practised. Shrubby forms may also be increased by layers, and *B. nana* by greenwood cuttings under glass.

A. Veins of lvs. 7 pairs or more, usually impressed above. Trees.

B. Lvs. large, 4-6 in. long, deeply cordate: cones cylindrical, racemose, 2-4.

1. *Maximowiczii*, Regel. Tree, 80-90 ft., with smooth, orange-colored trunk and dark reddish brown branchlets: lvs. long-petioled, broadly ovate, coarsely and doubly serrate, membranous, pubescent on younger trees, nearly glabrous on older ones: cones  $\frac{1}{2}$ -3 in. long, slender, nodding; fr. with very broad wings. Japan. B.M. 8337. S.I.F. 1:23. W.B. 90.—This is probably the most beautiful of all birches, perfectly hardy N. and of rapid growth; its large foliage and the yellow color of the trunk render it a highly ornamental and conspicuous park tree.

BB. Lvs. 2-5 in. long: cones solitary: wings narrower than the fr.

C. Under side of lvs. glaucescent: lvs. rhombic-ovate, cuneate at base with 7-9 slightly impressed pairs of veins.

2. *nigra*, Linn. (*B. rubra*, Michx.). RED or RIVER BIRCH. Tree 50-90 ft.: bark reddish brown, or silvery gray on younger branches, separating into numerous thin, papery flakes: branchlets pubescent: petioles scarcely  $\frac{1}{2}$  in. long: lvs. rhombic-ovate, acute, doubly serrate, pubescent when young, at length only on the veins beneath, pale or glaucescent beneath, 2-3 $\frac{1}{2}$  in. long: cones 1-1 $\frac{2}{3}$  in. long, cylindrical, ripening in May or June; scales pubescent, with erect, linear-oblong, nearly equal lobes. From Mass. south to Fla. and west to Kan. and Minn. S.S. 9:452. L.B.C. 13:1248. G. F. 2:591. Gn. 55, p. 161 (habit). W. B. 63. H.T. 122, 123.—

A moisture-loving, graceful tree, with slender, very numerous branches, and remarkable for its torn and ragged bark.

CC. Under side of lvs. light green: lvs. rounded or truncate at the base, with 8-14 pairs of impressed veins.

D. Shape of lvs. ovate or oblong-ovate, rounded and often cordate at the base, broadest about the middle; veins distinctly impressed above: petioles less than  $\frac{3}{4}$  in. long. See page 3566.

E. Cones peduncled, cylindric.

3. *utilis*, Don (*B. Bhojpattrā*, Wall.) Tree, 40-60 ft.: trunk with reddish brown bark: branchlets pubescent while young, not glandular: lvs. ovate, rounded at the base, acuminate, densely irregularly serrate, pubescent on the veins beneath, 2-3 in. long, with 8-12 pairs of veins: cones peduncled, cylindrical, 1-2 in. long, with erect oblong lobes, the middle one much longer. Himalaya. Japan. S.I.F. 1:23.—Not quite hardy N.

EE. Cones sessile or nearly sessile, ovoid or ovoid-oblong.

4. *lenta*, Linn. (*B. carpinifolia*, Ehrh.). CHERRY, SWEET, or BLACK BIRCH. Tree, 60-70 ft.: trunk dark reddish brown, young bark aromatic, of agreeable flavor: lvs. oblong-ovate, usually cordate at the base, sharply and doubly serrate, hairy beneath when young, nearly glabrous at length, 2-5 in. long: cones ovoid-oblong, 1-1 $\frac{1}{2}$  in. long; scales about  $\frac{1}{2}$  in. long, lobed

only at the apex, the middle lobe slightly longer. From Maine to Ala., west to eastern Ohio. S.S. 9:448. H.T. 124, 125. Em. 232.—Very handsome tree, round-headed, and with pendulous branches when older; attractive in spring, with its long staminate catkins. Bark and lvs. largely used in domestic practice; branches and foliage yield an oil very similar to oil of wintergreen, and employed for all conditions in which the latter proves useful; bark as well as the oil much used for flavoring.

548. *Betula pendula*.

cent outside. From Newfoundland west to Minn., south along the Alleghanies to the high peaks of N. C. and Tenn. S.S. 9:449. Em. 235. H.T. 126, 127.—One of the most valuable forest trees in the northern states, much resembling the former in habit. Var. *persicifolia*, Dipp., has larger and longer lvs., often ovate-lanceolate.

DD. Shape of lvs. ovate, broadest near the base and usually truncate or sometimes cordate; veins not impressed above; petioles to 1 in. long.

6. *ulmifolia*, Sieb. & Zucc. (*B. costata*, Trautv.). Tree, 50 ft.: bark yellowish brown; branches not, or slightly glandular; lvs. ovate, rarely oblong-ovate, irregularly doubly serrate, with 9–14 pairs of veins, long-acuminate, 2–3½ in. long, hairy when unfolding, glabrous at maturity; cones elliptic; scales glabrous, with short, rhombic or obovate lateral lobes; wings about half as broad as nutlet. Japan. Manchuria. S.I.F. 1:22. W.B. 63.

7. *Ermánii*, Cham. Tree, 60 ft.: trunk white; branches yellowish white or orange-colored; branchlets usually glandular and pubescent when young; lvs. broadly triangular-ovate, acuminate, irregularly coarsely serrate, 2–4 in. long, hairy when unfolding, with 7–10 pairs of veins; cones oblong; scales pubescent, with linear-oblong lobes, middle one somewhat longer; wings about one-third as broad as nutlet. N. E. Asia, Japan. S.I.F. 1:22. W.B. 63.—Handsome round-headed tree, with slender branches. See page 3566.

AA. Veins of lvs. 7 or less pairs, not impressed.

B. Wings usually broader than the nut.

C. Bark white.

D. Branchlets glabrous and glandular; lvs. usually rhombic-ovate; scales of strobiles with divergent broad lobes larger than the middle lobe.

8. *populifolia*, Ait. (*B. alba* var. *populifolia*, Spach). WHITE BIRCH. Small tree, exceptionally 40 ft., with smooth white bark; branchlets with numerous resinous glands; lvs. slender, petioled, triangular or deltoid, long-acuminate, coarsely doubly serrate, glutinous when

young, glabrous at length and shining; cones slender stalked, cylindric, about 1 in. long; bracts pubescent the lateral lobes divergent, about as long as the middle one. From New Brunswick to Del., west to Ont. S.S. 9:450. H.T. 118, 119. Em. 1:242.—A small, graceful, but short-lived tree, yet thriving in dry and poor soil. Var. *laciniata*, Loud. Lvs. incised-laciniate. Var. *pendula*, Loud. Branches distinctly pendulous. Var. *purpurea*, Ellwanger & Barry. Lvs. purple when young, green at length. *B. populifolia* × *B. papyrifera* is shown in G.F. 8:356. It has been found wild in several localities, but is apparently not in cult.

9. *pendula*, Roth (*B. verrucosa*, Ehrh. *B. alba*, Linn., in part). Figs. 548, 549. Tree, to 60 ft., with slender, in older trees usually pendulous, branches: young branchlets usually glandular; lvs. rhombic-ovate, ¾–2½ in. long, glutinous when young, glabrous, usually cuneate, sometimes truncate at the base, acuminate, doubly serrate; petioles slender, about 1 in. long; strobiles cylindric, about 1 in. long, slender-peduncled, usually pendulous; wings of nutlet about one and a half to two and a half times as broad as its body. Eu. to Japan. H.W. 2:15, p. 20. W.B. 76. Var. *Taüschii*, Rehd. (*B. japonica*, Sieb. *B. alba* var. *Taüschii*, Shirai. *B. pendula* var. *japonica*, Rehd.). Lvs. broadly ovate, truncate or sometimes subcordate at the base, sometimes puberulous beneath and often with tufts of hairs in the axils. S.I.F. 1:21. Var. *dalecarlica*, Schneid. (*B. laciniata*, Wahl. *B. hybrida*, Blom). Lvs. more or less deeply lobed with irregularly serrate-acuminate lobes; branches on older trees pendulous.—A very graceful tree. Var. *fastigiata*, Koch (*B. alba fastigiata*, Carr. *B. pendula pyramidalis*, Dipp.). With straight upright branches, forming a narrow columnar pyramid. G.C. III. 41:151. M.D.G. 16:164. Var. *tristis*, Schneid. With very slender, strongly pendulous branches, forming a round regular head. Var. *Yöungii*, Schneid. (*B. alba pendula Yöungii*, Moore. *B. pendula elegans*, Dipp. *B. alba elegantissima pendula*, Hort.). Branches very slender, strongly pendulous; primary branches spreading or recurved, forming an irregular picturesque head; similar in habit to the weeping beech. F. 1873, p. 60. R.H. 1869, p. 136. Gn. 6, p. 528. Var. *gracilis*, Rehd. (*B. alba laciniata gracilis pendula*, Hort. *B. elegans laciniata*, Hort.). Habit like the preceding, with lacinate lvs. Much slenderer and of slower growth than var. *dalecarlica*.

Var. *purpurea*, Schneid. (*B. vulgaris purpurea*, André. *B. alba atropurpurea*, Lauche. *B. pubescens atropurpurea*, Zabel). Lvs. dark purple. R.B. 4:185.

549. Leaves of *Betula pendula*. (× ½)

DD. Branchlets pubescent and slightly glandular or glandless; lvs. generally ovate, rounded at the base; bracts with the lateral lobes upright or spreading, shorter than the middle lobe.

10. *pubescens*, Ehrh. (*B. odorata*, Bechst. *B. alba*, Linn., in part). Tree, to 60 ft.: branches upright or spreading, rarely pendulous in old trees; branchlets pubescent and glandless; lvs. ovate or rhombic-ovate, 1–2 in. long, rounded, truncate or cuneate at the base, acute, usually unequally and doubly serrate, pubescent beneath, at least while young; strobiles cylindric, about 1 in. long, upright or nodding; scales puberulous, lateral lobes upright or spreading, rarely recurved. N. and Cent. Eu. to E. Siberia. H.W. 2, pp. 24, 25. Var.

*urticifolia*, Spach (*B. urticifolia*, Regel. *B. alba asplenifolia*, Hort.). Lvs. small, deep green, irregularly incised. Var. *variegata*, Zabel (*B. alba foliis variegatis*, Hort.). An inconstant form with variegated lvs. There are also a number of geographical varieties as var. *carpatica*, Koch; var. *songarica*, Regel; var. *tortuosa*, Koehne; var. *Murithii*, Grenf., which are rarely met with in cult. and horticulturally are of no importance. —In the wild state this species is generally found in moist places, often in swamps, while the preceding species prefers drier situations.

11. *papyrifera*, Marsh. (*B. papyracea*, Ait. *B. grandis*, Schrad.). PAPER OR CANOE BIRCH. Figs. 550, 551. Tree, 60–80, exceptionally 120, ft.: branchlets slightly glandular, hairy when young: lvs. ovate, narrowed to cordate at the base, acuminate, coarsely and usually doubly serrate, pubescent on the veins beneath or nearly glabrous,  $1\frac{1}{2}$ – $4\frac{1}{2}$  in. long: strobiles peduncled, 1–2 in. long; scales with short and broad divergent lateral lobes. Northern states from the Atlantic to Pacific coast. S.S. 9:451. Em. 238. G.F. 8:223. H.T. 120, 121. I.T. 4:125.—Ornamental tree, with very white trunk and a loose, graceful head when older. Bark known for its use in making Indian canoes. Var. *cordifolia*, Regel (*B. pyrifolia* and *B. platyphylla*, Hort.). Lvs. broadly ovate, usually cordate. S.S. 14:724. Var. *minor*, Tuckerm. Low, bushy tree with smaller lvs. and frs. Mts. of New England and N. Y.

cc. Bark orange-brown: branchlets glandular and hairy when young: lateral lobes of scales upright, shorter than the middle lobe.

12. *occidentalis*, Hook. (*B. Lyalliana*, Koehne. *B. papyracea* var. *occidentalis*, Dipp.). Tree, to 100 ft.: branches in older trees often pendulous: lvs. ovate, 3–4 in. long, usually rounded at the base, acute, coarsely and mostly doubly serrate, resinous while young and villous on the veins, glabrous at maturity except on the puberulous veins: strobiles cylindric,  $1\frac{1}{4}$ – $1\frac{1}{2}$  in. long; scales ciliate, with rhombic-ovate upright lateral lobes, about half as long as the oblong middle lobe. B. C. to Wash. S.S. 14:725.

bb. Wings narrower than the nut: shrubs, 1–15 ft.: lvs. small, short-petioled: cones erect.

c. Branchlets glandular, not pubescent.

13. *glandulosa*, Michx. Only 1–4 ft.: lvs. short-petioled, rounded or cuneate at the base, orbicular or broadly ob-ovate, obtuse, dentate, glabrous,  $\frac{1}{4}$ – $1\frac{1}{2}$  in. long: strobiles peduncled,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long; lobes of scales nearly equal, slightly spreading; wings of nut-

orbicular or oval, acute or obtuse, coarsely dentate, pale and glabrous or pubescent beneath,  $\frac{1}{2}$ –2 in. long: strobiles peduncled,  $\frac{1}{2}$ –1 in. long; lateral lobes of the pubescent scales spreading, shorter than the middle one; wings of nutlet half as broad as its body or narrower. Newfoundland to Minn., south to Ohio. B.B. 1:511. W.B. 71. Var. *fastigiata*, Rehd. (*B. humilis fastigiata*, Hort.). Shrub, with upright branches, forming a narrow pyramid: branchlets soft pubescent: lvs. broadly rhombic to suborbicular, 1– $1\frac{1}{2}$  in. long, broadly cuneate at base, pubescent beneath only on the veins, resin-dotted on both sides.

15. *nana*, Linn. Low, spreading, rarely 4 ft.: lvs. orbicular or cuneate-obovate, crenate, rounded at apex, glabrous,  $\frac{1}{4}$ – $\frac{3}{4}$  in. long: strobiles nearly sessile,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long: the upper scales usually entire, the lower ones 3-lobed; wings of nutlets very narrow. Arctic N. E. Amer., N. Eu., Siberia. B.B. 1:511. W.B. 71.—A low, graceful shrub for rockeries and rocky slopes.

*B. acuminata*, Wall.=*B. alnoides*.—*B. al-skana*, Sarg. Allied to *B. occidentalis*. Tree, to 40, rarely 80 ft.: bark grayish white: branchlets densely glandular: lvs. rhombic-ovate,  $1\frac{1}{2}$ –3 in. long, truncate to broadly cuneate pubescent on the veins beneath or finally glabrous; petiole about 1 in. long: scales of strobiles ciliate. Alaska. S.S. 14:726.—*B. alleghaniensis* Brit. Intermediate between *B. lenta* and *B. lutea*. Bark either close and furrowed or peeling off in thin flakes: young branchlets pubescent: lvs. usually cordate at base and pubescent beneath: strobiles obovate-oblong, about 1 in. long; scales  $\frac{1}{4}$  in. long, 3-lobed about to the middle. Quebec and Mich. to Ga.—*B. alnoides*, Hamil. (*B. acuminata* Wall. *B. cylindrostachya*, Wall.). Allied to *B. Maximowiczii*. Tree, to 60 ft.: young branchlets pubescent; bark brown: lvs. ovate-oblong to ovate-lanceolate,  $2\frac{1}{2}$ –6 in. long, rounded at the base, doubly cuspidate-serrate, with 10–13 pairs of veins: strobiles in racemes. Himalayas, S.W. China. W.B. 90.—*B. alpestris*, Fries=*B. intermedia*.—*B. Borgrævei*, Zabel (*B. papyrifera* × *B. pumila*). Shrubby. Intermediate between the parents, but more similar to *B. pumila*. Raised at Hann. Muenden, Germany, from American seed.—*B. cærulea*, Blanch. Allied to *B. pendula*. Tree, to 60 ft.: young branchlets hairy: lvs. ovate, 2– $3\frac{1}{2}$  in. long, rounded or cuneate at base, acuminate, sharply serrate, dull bluish green above, slightly hairy along the veins beneath: scales of strobiles similar to those of *B. populifolia*. Vt., Me. S.M. 201.—*B. carpinifolia*, Sieb. & Zucc.=*B. grossa*.—*B. carpinifolia*, Ehrh.=*B. lenta*.—*B. corylifolia*, Regel. Allied to *B. nigra*. Lvs. broadly elliptic or obovate,  $1\frac{3}{4}$ – $2\frac{1}{2}$  in. long, coarsely dentate, silky on the veins beneath, with 10–14 impressed pairs of veins: strobiles cylindric. Japan. S.I.F. 2:14. W.B. 60.—The plant cult. under this name is usually *B. Ermanii*.—*B. cylindrostachya*, Wall.=*B. alnoides*.—*B. dahurica*, Pall. Allied to *B. pubescens*. Tree, to 60 ft.: bark brown: branchlets glandular, hairy when young: lvs. ovate, 1–2 in. long, pubescent on the veins beneath: strobiles oblong; wings of nutlet half as broad as body or less. Dahuria, Manchuria. Pallas, Fl. Ross. 39.—*B. excelsa*, Ait. (*B. alba* var. *excelsa*, Regel). Allied to *B. pubescens*. Large tree: bark yellowish brown: young branchlets densely pubescent: lvs. broadly ovate to obovate, 1– $2\frac{1}{2}$  in. long, rounded or subcordate at the base, acute, pubescent beneath: strobiles cylindric-oblong, upright or nodding; lateral lobes of scales slightly shorter than the middle one. Of unknown origin. W.D.B. 2:95. N.D. 3:52.—*B. fontinalis*, Sarg. (*B. occidentalis*, Nutt., not Hook. *B. rhombifolia*, Nutt., not Tausch). Allied to *B. occidentalis*. Small tree, to 40 ft. or shrubby: bark dark bronze color, lustrous: branchlets glandular: lvs. broadly ovate, 1–2 in. long, truncate to broadly cuneate, sharply, often doubly serrate: strobiles cylindric-oblong, 1– $1\frac{1}{2}$  in. long; scales glabrous or puberulous. B. C. to Calif., east to Dak. and Colo. S.S. 9:453 (as *B. occidentalis*).—*B. fruticosa*, Pall. (*B. Gmelinii*, Bunge). Allied to *B. glandulosa*. Shrub, to 15 ft.: branchlets glandular and pubescent: lvs. ovate-elliptic,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. long, glabrous at length and usually glandular beneath: strobiles oblong-cylindric,  $\frac{3}{4}$ –1 in. long, wings about as broad as nutlet. Siberia, Manchuria. Pallas, Fl. Ross. 40.—*B. globosipica*, Shirai. Allied to *B. ulmifolia*. Tree, to 60 ft.: bark grayish brown: lvs. broadly rhombic-ovate,  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. long, short-acuminate, unequally serrate, with about 10 pairs of veins, pubescent on the veins beneath: strobiles subglobose or ovoid, about  $1\frac{1}{2}$  in. long; scales deeply 3-lobed with spatulate lobes. Japan. S.I.F. 1:21. W.B. 68.—*B. Gmelinii*, Bunge=*B. fruticosa*.—*B. grossa*, Sieb. & Zucc. (*B. carpinifolia*, Sieb. & Zucc.). Tree: branchlets glabrous: lvs. ovate, 2–4 in. long, unequally serrate, with 10–15 pairs of veins, pubescent on the veins beneath and glandular-punctate: strobiles nearly sessile, elliptic-ovoid; middle lobe of the scale slightly longer than the lateral ones. Japan. S.I.F. 1:22.—*B. humilis*, Schrank. Allied to *B. glandulosa*. Shrub, 2–6 ft.: branchlets glandular and slightly pubescent at first: lvs. ovate or suborbicular,  $\frac{1}{2}$ – $1\frac{1}{4}$  in. long, crenately serrate, glabrous: strobiles ovoid, about  $\frac{1}{2}$  in. long. N. and W. Eu., N. Asia. G.W.H. 2:149. H.W. 2:

551. Catkin of *Betula papyrifera*. (×  $\frac{1}{2}$ )

550. Staminate catkin (natural size) and flowers (enlarged) of *Betula papyrifera*.

let sometimes as broad as its body. Newfoundland to Alaska, south to Mich., and in the Rocky Mts. to Colo. B.B. 1:510.

cc. Branchlets pubescent or nearly glabrous, not glandular.

11. *pumila*, Linn. Usually 2–8, rarely 15, ft.: branchlets tomentose or pubescent, at least when young: lvs.

p. 26. R.F.G. 12:1279.—*B. intermedia*, Thomas (*B. alpestris*, Fries. *B. pubescens* × *B. nana*). Shrub: lvs. orbicular or ovate,  $\frac{1}{2}$ –1 in. long, crenate-serrate, usually pubescent while young, and often glutinous, finely glabrous: strobiles oblong; lateral lobes of scale upright and usually shorter than the middle one. N. Eu.—Natural hybrid; very variable.—*B. Jäckii*, Schneid. (*B. lenta* × *pumila*). Shrub: bark of the odor of *B. lenta*: lvs. usually obovate, 1–2 in. long, usually with about 7 pairs of veins: strobiles oblong,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long; lateral lobes of scales spreading, somewhat shorter than the middle one. Originated at the Arnold Arboretum. G.F. 8:245.—*B. kerdica*, Evans. Allied to *B. occidentalis*. Tree, to 40 ft.: bark grayish white or light reddish brown: branchlets glabrous, not or slightly glandular: lvs. ovate,  $1\frac{1}{2}$ –2 in. long, cuneate or rounded at the base, irregularly, often doubly serrate, glabrous: strobiles cylindrical-oblong, about 1 in. long, glabrous. Alaska. S.S. 14:723.—*B. Kähnei*, Schneid. (*B. papyrifera* × *peadula*). Intermediate between the parents. Tree: branchlets sparingly pubescent: lvs. ovate, 2– $3\frac{1}{2}$  in. long, usually truncate at base, acuminate; rather finely and doubly serrate: scales of strobiles similar to those of *B. papyrifera*. Origin unknown.—*B. luminifera*, Winkl. Allied to *B. alnoides*. Lvs. ovate, subcordate at the base, serrate with acuminate teeth, 3–5 in. long: strobiles solitary, 2–3 in. long. Cent. China. W. 92.—*B. Medwedewii*, Regel. Allied to *B. utilis*. Tree: young branchlets hairy: lvs. broadly ovate to obovate, 2–3 in. long, rounded or sometimes subcordate at the base, short-acuminate, glabrous or pubescent on the veins beneath: strobiles cylindrical-oblong, 1– $1\frac{1}{4}$  in. long; wings of nutlets: often 4 times narrower than its body. Caucasus. Gt. 36, p. 384.—*B. occidentalis*, Nutt., not Hook.—*B. fontinalis*, —*B. Purpusii*, Schneid. (*B. lutea* × *pumila*). Shrubby or small tree: lvs. oblong-ovate, 1–2 in. long, with 7–9 pairs of veins, soft-pubescent beneath. Intro. to Eu. from Mich.—*B. Raddeana*, Trautv. Tree: lvs. ovate-pubescent on the veins beneath, with 6–7 pairs of veins, 1–2 in. long: strobiles oblong, upright,  $\frac{3}{4}$  in. long; wings as broad as nutlet. Caucasus. Gt. 36, p. 384.—*B. rhombifolia*, Nutt.—*B. fontinalis*.

ALFRED REHDER.

**BIARUM** (old and obscure name). Incl. *Ischarum*. *Araceæ*. Dwarf, tuberous perennials of the same tribe with our native jack-in-the-pulpit. They are hardy in England, but probably are suitable only for pot-culture in the Northern United States.

Biarums have a spathe which is tubular at the base, mostly with a long limb, and usually a long tail-like spadix; otherwise much as in *Arum*. They grow a few inches high. Odd. Little known in Amer. A few species in Eu. and Asia Minor.

**tenuifolium**, Schott (*Arum tenuifolium*, Linn.). Lvs. linear-lanceolate or spatulate, appearing after the fls. decay: spathe long-acuminate, at length recurved and twisted spirally, about 10 in. long, outside green, streaked purple; inside dull purple, spotted; margins wavy; spadix 15 in. long. Spain. B.M. 2282.

**Pyrámii**, Engler (*Ischarum Pyramii*, Schott). Lvs. oblong above the middle, narrowing abruptly to a very long petiole, resembling *Calla palustris*: spathe green outside, shining, velvety purple within, shorter and broader than in *B. tubiflorum*, at length revolute; tube swelling, connate only at the very base; spadix thicker and shorter. Syria. B.M. 5324.

**Bövei**, Blume. Lvs. similar to *B. Pyramii*; spathe-tube connate a fourth of its length; blade of spathe longer and more narrowly lanceolate, green outside, dark purple within. Syria, Asia Minor. L. H. B.

**BIDENS** (Latin, *two-teeth*, in reference to the awns). *Compositæ*. BUR-MARIGOLD. STICK-TIGHTS. TICK-SEED. Annual, or rarely perennial, herbs, mostly American, related to *Coreopsis*, *Dahlia*, and *Cosmos*.

Leaves opposite, serrate or incised, often pinnately or ternately divided: heads radiate or discoid; rays yellow or white; disk yellow; involucre double, the outer set of bracts green and more or less foliaceous, the inner of quite different texture and shape, more appressed, thinner, more scarious and striate: achenes flat or angled; pappus of 2–4 stiff bristles or awns, usually retrosely barbed.—Plants grown as garden annuals. *B. frondosa*, a common weed, is the well-known boot-jack bur, or stick-tight.

A. Achenes obovate or cuneate-oblong, more or less flattened or triangular, the faces uni-costate: texture of lf. medium.

B. Size of achenes small (1–2 lines long) with firm glabrous margins: inner involucre dark dotted.

**coronata**, Fisch. (*Coreopsis aurea*, Ait.). St. 1–4 ft. high, branched above, glabrous or nearly so: lvs. ter-

nately or pinnately divided: outer involucre about equaling the dark-dotted inner: achenes dark, very small, 1–2 lines long, narrowly cuneate, 3-angled, margin firm and glabrous; pappus of 2–4 minute awns and some chaff. S. E. U. S.—Very variable.

BB. Size of achenes larger (2–4 lines long) with hispid margins: involucre not dotted.

**trichosperma**, Brit. (*Coreopsis trichosperma*, Michx.). St. tall, 2–5 ft. high, glabrous, branched above: lvs. pinnatifid: outer involucre about equaling the undotted inner: achenes dark, larger,  $2\frac{1}{2}$ –4 lines long, cuneate, moderately flat, margin firm, usually pubescent; pappus of 2 upwardly hispid broad-based awns about  $\frac{1}{2}$  line long. E. U. S. Var. **tenuifolia**, Brit. Lf.-segms. narrowly linear: achenes 2–3 lines long.

**aristosa**, Brit. (*Coreopsis aristosa*, Michx.). St. 1–4 ft. high, branched above, nearly or quite glabrous: lvs. pinnatifid, often pubescent beneath: outer involucre about equaling the undotted inner: achenes olive or brownish, large, 2–4 lines long, broad and very flat 1– $2\frac{1}{2}$  lines broad, abruptly contracted at summit, margin thin and hispid, often crenulate; pappus awns 2, each 1–2 lines long, divergent, stramineous, upwardly or downwardly barbed, or sometimes entirely wanting. Cent. U. S. B.M. 6462. R.H. 1869:72.

AA. Achenes linear-spindle-shaped, tapering gradually above, angled or costate: texture of lf. usually firmer.

B. Lvs., in part, finely dissected: rays large, golden yellow.

**grandiflora**, Balb. St. 1–4 ft. high, branched, glabrous and somewhat glaucous: lvs. pinnatifid, the divisions either lanceolate and serrate or dissected into narrowly linear divisions: outer involucre about equaling the more or less hirsute inner; rays large, golden yellow: achenes 3–6 lines long; awns 2, downwardly barbed, about 1 line long. Mex.—A showy plant sometimes cult. in Amer.

BB. Lvs. or their divisions lanceolate to ovate: rays pale yellow or whitish.

**Warszewicziana**, Regel. Erect, glabrous perennial: lvs. simple, or pinnate or rarely bipinnate, the lobes lanceolate or ovate-lanceolate: heads corymbose, the involucral bracts ciliate; petals whitish or yellowish, of medium size: achenes compressed, angular, the angles ciliate. Guatemala.—Hardy N. only with protection.

**pilosa**, Linn. St. 2–5 ft. high, much branched, nearly glabrous: lvs. ternate or pinnate, divisions lanceolate, incised-serrate with somewhat rounded teeth: outer involucre about equaling the glabrous or minutely puberulent inner: rays short, 1–3 times as long as the involucre, creamy-white: achenes 4–7 lines long; awns 2–4, downwardly barbed,  $1\frac{1}{2}$  lines long. Tropics.—Sometimes grown in botanic gardens.

*B. dahlioides*, Wats. A perennial with dahlia-like tubers. Mex. G.C. III. 48:226. R.H. 1910, p. 475.

K. M. WIEGAND and N. TAYLOR.

**BIENNIALS**. Plants that bloom a year after the seeds are sown, then make seeds and die. Familiar examples among vegetables are cabbage, turnips, celery and onions, but in warm or long-season climates they become annuals. Even in northern gardens, celery, carrots and beets, if permitted to crowd, will often run to seed the first year. On the other hand, many biennials, such as hollyhocks and others, are practically perennial because they self-sow, or multiply by offshoots, so that there is little danger of losing them. Such cases give rise to discussion as to whether a plant is an annual, biennial, or perennial, but the practical problems are few and simple, and are commonly connected with the following favorite flowers:

Hollyhock (*Althæa rosea*), snapdragon (*Antirrhinum majus*), English daisy (*Bellis perennis*), Canterbury

bells (*Campanula Medium*), steeple bellflower (*Campanula pyramidalis*), sweet william (*Dianthus barbatus*), foxglove (*Digitalis purpurea*), horned poppy (*Glaucium luteum*), French honeysuckle (*Hedysarum coronarium*), morning campion (*Lychnis dioica*), evening campion (*Lychnis alba*), rose campion (*Lychnis Coronaria*), honesty (*Lunaria annua*; *L. biennis*), pansy (*Viola tricolor* ×) tufted pansies (*Viola cornuta* ×).

Every beginner desires to know what to do with the seedlings that spring up in every border by the dozen or hundred around sweet williams, foxgloves, larkspurs, hollyhocks, and the like. All that is necessary is to thin the seedlings and transplant some at any convenient time before autumn to the positions in which they are to bloom next year. This practice, however, does not suit those who want only the finest varieties, for these do not come true from seed. Therefore, they must buy seeds every year of the best varieties of highly-bred groups, such as sweet william, foxglove, English daisy, Canterbury bells, and hollyhocks, or else buy plants. If a very fine variety appears, it is desirable to multiply it by methods other than seed-sowing if possible, e.g., by offsets, cuttings or division. Named larkspurs cannot be kept a long time, owing to disease, unless propagated by cuttings every year. Double hollyhocks can be maintained by division and by keeping the leaves coated constantly with ammoniacal copper carbonate, which is less unsightly than bordeaux. A German cultivator avers that one should save seeds from diseased hollyhock plants instead of healthy ones, and declares that he has raised 1,500 such seedlings that proved immune. So far as known, this has not been thoroughly tested in America.

Those who do not want such expense and care, and prefer lusty, many-flowered plants of ordinary varieties to sickly specimens of high-bred types, will find it cheaper and easier to collect seeds as they ripen and sow them immediately. Color discords can be mitigated by thinning out or transplanting offenders. This is the way to secure gorgeous masses of blue delphiniums, if one cares more for color than size and form.

What to do with famous English spring flowers that dislike our hot summers is another common problem. The beginner finds that violets, pansies, daisies, primroses, polyanthus, and auriculas, will not bloom all summer, as they do in the cool, moist climate of England, unless in similar climates (e.g., at the seashore or in the northern tier of states), and then only with special care in seed-picking, cutting-back, fertilizing, watering. At best the summer bloom is only intermittent, rarely massive, and the common practice is to treat these species frankly as spring bedding plants (April 15 to May 15 near New York), and when their glory is past discard them or move them to some moist, shady spot in which there is a better chance for casual summer bloom and a tolerable autumn show than in the hot sunny border.

Those who cannot afford greenhouses may easily have larger and better flowers of the species just named by the use of coldframes. They are particularly enjoyable while the snows of March are on the ground.

In these days of cheap greenhouses, everyone wants cut-flowers the year round, especially long-stemmed, long-lasting kinds in many colors. Consequently snapdragons and ten-weeks stocks have become popular.

The commonest way of raising biennials is to sow the seeds in an outdoor seed-bed in summer, and in autumn transplant the seedlings to their permanent quarters. English books have always disappointed Americans by advising that this be done in June. But in America the best time is early August. Not only does one save two months' care, but June-sown biennials and perennials in our climate make plants that are too large to winter easily in coldframes, and they often try to bloom just when the killing frost of autumn comes.

A much better way is to sow the seeds in flats in coldframes (for protection against summer showers) and to winter the young plants in frames. This is the way to secure the finest white foxgloves, Canterbury bells, larkspurs, and steeple bellflowers.

Professional gardeners often prefer to treat biennials as half-hardy annuals, i.e., they sow the seeds in greenhouses in March and set the young plants outdoors in May. On new places this saves a year; it is especially worth doing with snapdragons and intermediate stocks.

Many of the flowers named above are technically perennial, but in practice they are so short-lived that it usually pays to raise a fresh batch from seed every year.

WILHELM MILLER.

**BIFRENARIA** (Latin for *twice* and *strap*, referring to the two stalks of the pollinia). *Orchidaceæ*. Epiphytic plants, with pseudobulbs, plicate-veined lvs., and lateral infl.: fls. sometimes single and large, or more frequently smaller and several to many in a raceme; sepals about equal, spreading, the lateral adnate to the foot of the column; petals similar to the dorsal sepal; lip articulated to the apex of the column-foot, 3-lobed; pollinia 4, on 2 stalks.—About 25 species in Trop. Amer.

552. *Bifrenaria Harrisonia*. (× ¼)

A. Foot of column or mentum short and broad: fls. deep yellow with golden purple spots.

**aurantiaca**, Lindl. Pseudobulbs ovoid, up to 1½ in. long: lvs. up to 8 in. long and 2 in. broad: raceme few- to several-flid.; fls. about 1 in. across, deep yellow and spotted with golden purple. Guiana and Trinidad. B.M. 3597. B.R. 1875.

AA. Foot long, acute: fls. not colored as above.

B. Fls. large, 1-3.

C. Lip purple, darker-veined: fls. ivory-white.

**Harrisonia**, Reichb. f. Fig. 552. Pseudobulbs broadly ovoid, up to 2½ in. long, 1-ld.: lvs. up to 1 ft. long and 4 in. broad: peduncle with 1 or 2 ivory-white large fls. about 3 in. across, the lip purple with darker veins. Brazil. Lind. 5:239. B.R. 897. B.M. 2927 (as *Maxillaria*).

CC. Lip white, yellow or rose: fls. apple-green.

**inodora**, Lindl. Resembles *B. Harrisonia* in pseudobulbs, lvs., infl. and size of fls.: sepals apple-green; petals of the same color but brighter, smaller; lip white, yellow or rose; spur half as long as ovary. Brazil.

BB. Fls. small, several.

**vitellina**, Lindl. Pseudobulbs ovoid, up to 1½ in. long, 1-ld.: lvs. up to 1 ft. long and 1½ in. broad: fls. about 1 in. across, orange-yellow, with a purple spot on the lip; lip cordate. Brazil. B.R. 25:12. (As *Maxillaria*.)

*B. bicornaria*, Reichb. Allied to *B. aurantiaca*. Fls. orange-colored. Brazil.—*B. Fuerstenbergiana*, Schlecht. Fls. yellow Brazil.—*B. melanopoda*, Klotzsch. Sepals and petals light green, lip fringed, white. Brazil.—*B. tetragona*, Hort. Fls. wax-like with greenish sepals and petals. Brazil.—*B. tyrianthina* var. *Goodsonae*, Reichb. Fls. light purple.

GEORGE V. NASH.

**BIGELÔVIA** (after Dr. Jacob Bigelow, author of *Flora Bostoniensis*, Medical Botany of United States, etc.). Frequently written *Bigelowia*. *Compósitæ*. More than thirty species of western American herbs or low shrubs, one or two of which are sometimes offered by dealers in native plants.

Heads 3-30-fld., without ray fls., small; involucre narrow, its bracts mostly lacking herbaceous tips. The only species in cult. is the one originally described, which resembles a goldenrod, to which *Bigelovia* is very closely related. It differs in not having the racemiform infl. of goldenrods. Prop. by cuttings and by seed.

**gravêolens**, Gray (*Bigelôwia dracunculoides*, DC.). Low shrub, 1-3 ft. high, densely white-tomentose when young, smoother in age, much branched, very leafy, malodorous only in drying; lvs. linear, 1-2 in. long; fl.-heads yellow, 5-8 lines high, very numerous, crowded, in terminal corymbose cymes, rayless. Alkaline soils Dak. to B. C. and south to S. Calif. and Ariz.—An extremely variable species. **Var. albicaulis** is more permanently and densely woolly, dwarfier, and has been recommended in the West for low hedges and edgings.

N. TAYLOR.†

**BIGNAY:** *Antidesma*.

**BIGNÔNIA** (The Abbé Jean Paul Bignon, 1662-1743, Court librarian to Louis XIV). *Bignoniaceæ*. Woody tendril-climbers, grown in the open in the warmer parts and also under glass.

Leaves opposite, compound (in proper representatives of the genus), the terminal lft. often represented by a tendril: fls. large, tubular or bell-shaped, enlarged above the calyx, obtusely 5-lobed, and more or less 2-lipped, the calyx slightly or not at all toothed; stamens 4, paired, and sometimes a sterile rudiment: fr. a 2-celled septifragal caps. flattened parallel with the partition; valves thickened; seeds winged.—The genus *Bignonia* is variously understood. By Bentham & Hooker it is regarded as a polymorphous group of 150 or more species; by Schumann (in Engler & Prantl) it is reduced to 2 species with claw-like (not disk-bearing) tendrils, *B. exoleta*, Vell., and *B. Unguis-cati*, Linn. By the former authors *Bignoniaceæ* is held to contain about 50 genera, and by the latter about 100. Schumann distributes the bignonias of Bentham & Hooker into several genera: the common East American *B. capreolata* goes to *Doxantha*, a disposition that has not

been accepted by American botanists. As here employed, *Bignonia* is deprived of many of the tropical species that have been placed in it in horticultural literature, and the student is referred to *Clytostoma*, *Cydistia*, *Phædranthus*, *Pithecoctenium*, *Pyrrostegia*, *Tabebuia* and others. Very recently the name *Bignonia* has been used for the species described in this work under *Campsis*, because *Bignonia* originally was based mainly on *B.*

553. Cross-section of stem of a tropical climber of the bignonia family.

*radicans* = *Campsis radicans*. In this case, the generic name for *B. exoleta* and *B. Unguis-cati* above becomes *Doxantha*; otherwise, this latter name remains a synonym of *Bignonia*, although, as stated above, Schumann has used it as the generic name of *B. capreolata*; but the correct name for this plant appears to be *Anisostichus capreolata*, of Bureau. The other species described here under *Bignonia* probably belong to different genera, but their correct botanical affinity has not yet been ascertained.

The bignonias are American climbers, mostly tropical, some of them and their allies constituting lianas of great length; and the profusion and beauty of

their flowers makes them conspicuous and interesting. The stem of some species shows a 4-parted or cross-like arrangement in cross-section, whence the name "cross-vine;" and on this account, some of the natives of Spanish America attribute sacred virtues or attributes to the plants, calling them "bejucos de la cruz." Fig. 553.

The bignonias (using the term in the horticultural sense) are strong and rapid-growing evergreen greenhouse climbers, requiring considerable space for their best development, such as the roof of a large conservatory, or the back wall of a lean-to greenhouse. If convenient, they should be planted out under the plant stage of the greenhouse, or otherwise in boxes placed on the stage. A box 5 feet by 1½ feet and 1 foot deep will be found a convenient size for them. As with most greenhouse climbing plants, the roots like considerable freedom; but with bignonias the roots must be somewhat restricted (though not to the limitations of a flower-pot), otherwise an immense growth and few flowers will be the result. They are not very fastidious as to soil. A good, fibrous loam, to which one-third well-decomposed cow or sheep manure has been added, suits them admirably. A winter temperature of 45° to 50°, with a gradual rise as the days lengthen, should be given them, admitting air freely whenever the weather is favorable. They like plenty of moisture at the roots—especially during the spring and summer (the growing season)—but perfect drainage should be insured, as the soil at no time must become saturated or sour. Except when in flower, a good syringing on all fine days will be very beneficial. They should also be sprayed once or twice a week with a moderately strong solution of kerosene emulsion, or kerosene and water, to keep them free from mealy-bug, as they are very subject to this pest. The vines should be trained so as to allow a free circulation of air among the branches for the purpose of ripening the wood, as upon this depends the assurance of flowers. All superfluous branches and weak shoots should be removed, and before the growing season begins all the branches should be shortened from 1 to 3 feet, according to their strength; this will throw the energy of the plant into the lateral buds, which will produce the flowering branches, providing the wood has been properly ripened the previous season.—Propagation is effected by cuttings taken in late spring and inserted in sand under a bell-glass, or in a propagating-box, in a warm temperature. Choose, if possible, stout, short-jointed lateral growths for the purpose. They must be carefully watered until rooted, which usually takes from six to ten weeks. (E. J. Canning.)

A. Lvs. compound: fls. yellow or yellow-red.

**Chàmberlaynii**, Sims (*Anemopægma racemodsum*, Mart.). Glabrous: lfts. ovate-acuminate, glabrous, shining above, paler beneath, more or less tapering at base: fls. tubular, contracted below, 3-4 in. long, the limb comparatively short and spreading, bright yellow; cluster many-fld. Brazil. B.M. 2148. F.S. 3:235. P.M. 14:3-4.—One of the freest and most beautiful tropical climbers, flowering well in a small house. Should be in all collections of tropical plants. This plant bears the name of Consul-General Chamberlayne, stationed about 100 years ago in Brazil. The genus *Anemopægma* is kept distinct by many.

**Ūnguis-cāti**, Linn. (*B. Tweediana*, Lindl., not Griseb.). Lvs. evergreen; lfts. 1 pair, lanceolate and pointed, cordate, 3 in. or less long, with 3-parted claw-like tendrils: fls. trumpet-shaped, 2 in. long, allamanda-like, tube clear bright yellow, upper surface of limb orange-yellow, and throat with orange lines, the limb of rounded, spreading lobes and from 2-4 in. across. Argentina. B.R. 26:45. Gn. 40:10.—Will stand a little frost if grown in the open in the S. *B. Tweediana*, Griseb., is a *Macfadyena*.

**capreolata**, Linn. (*B. crucigera*, Linn., in part. *Anisostichus capreolata*, Bur. *Doxantha capreolata*, Miers). TRUMPET-FLOWER. CROSS-VINE. QUARTER-VINE. Climbing to great heights (often 50 ft. or more), glabrous, evergreen: lvs. stiffish, ending in a branched tendril that cordate by small disks; lfts. stalked, oblong-acuminate, cordate, entire: fls. in many 2-5-fl. short-peduncled cymes, yellow-red and lighter within, tubular (2 in. long), with a stout limb. Native from Md. south and west, and often a pest in orchards, climbing on the trees. B.M. 864. Gng. 1:370-1.—Handsome vine for outdoor use. Good for covering walls. Sometimes grown in conservatories. Not hardy N., but will survive in Mass. as a creeping plant.

Var. **atrosanguinea**, Hook. f. (*B. atrosanguinea*, Hort.). Lvs. longer and narrower: fls. dark purple, the lobes short and triangular-ovate. B.M. 6501. F.R. 2:27.—Handsome.

AA. Lvs. simple, opposite (horticultural names, plants evidently not of this genus: perhaps *Tabebuia*).

**magnifica**, Bull. Free-growing and floriferous, needing warm treatment: lvs. ovate-elliptic, stalked, entire: fls. paniced, large ( $3\frac{1}{2}$  in. across), ranging from mauve to purple-red, the throat primrose. limb wide-spreading. Colombia. G.C. II. 12:73.—Requires hot sunny position under tropical conditions.

**regalis**, Hort. Lvs. elliptic-lanceolate; fls. large, yellow and red. Guiana.—Requires warm treatment.

**argyreο-violascens**, Hort. Lvs. ovate, cordate at base, short-stalked, purple when young, but becoming beautifully veined and blotched with white: fls. purple. S. Amer. (?). I.H. 13:469.

*B. adenophylla*, Wall.=*Heterophragma*.—*B. æquinoctialis*, Linn.=*Cydista*.—*B. alba*, Hort.=*Pithecoctenium*.—*B. buccinataria*, Mair.=*Phædranthus*.—*B. Cherère*, Lindl.=*Phædranthus*.—*B. ekrysantha*, Hort.=*Tabebuia*.—*B. grandiflora*, Thunb.=*Campsis*.—*B. jasminoides*, A. Cunn.=*Pandorea*.—*B. Lindleyi*, DC.=*Clytostoma*.—*B. littordis*, HBK. Hairy on branchlets: lfts. roundish-ovate, acuminate, hairy: fls. red, pubescent, funnel-shaped, in axillary panicles. Mex.—*B. pallida*, Lindl.=*Tabebuia*.—*B. picta*, Lindl.=*Clytostoma*.—*B. purpurea*, Hook.=*Clytostoma*.—*B. radicans*, Linn.=*Campsis*.—*B. rugosa*, Hook. Hairy: lfts. 2, oblong-acuminate: fls. axillary, 2-2½ in. long, primrose-color, limb short. Venezuela. Probably a *Macrodiscus*. B.M. 7124.—*B. speciosa*, Grah.=*Clytostoma*.—*B. suaveolens*, Thunb.=*Stereospermum*.—*B. Thunbergii*, Hort.=*Campsis*.—*B. venusta*, Ker.=*Pyrostegia*. L. H. B.

BILIMBI: *Averrhoa*.

**BILLARDIÈRE** (after J. J. Labillardière, French botanist and traveler). *Pittosporaceæ*. Six or eight species of tender Australian undershrubs, with twining branches, and terminal flowers suitable for outdoor planting South and for growing under glass.

Leaves entire or sinuate, alternate: fls. solitary or 2-3 together, sometimes as many as 15, yellow, purple or rarely blue, showy in *B. longiflora*: fr. succulent or fleshy, edible in some species. Prop. by cuttings under a bell-jar or by seeds, which, at least in England, are produced freely in some of the species. *B. longiflora* and *B. scandens* are cult. abroad as greenhouse climbers. *B. cymosa* is cult. outdoors at Santa Barbara, Calif.

**scandens**, Smith. Fig. 554. Sts. twining, often extensively so: lvs. variable, ovate-lanceolate to linear, obtuse or with a recurved point, 1-2 in. long, entire or undulate: fls. solitary, rarely 2 together, greenish yellow, violet or purple. Sweet. Fl. Aust., pl. 54. B.M. 801.—Offered by Montariso Nurseries, Santa Barbara, Calif.

**cymosa**, F. Muell. Shrubby with the branches more or less twining: lvs. oblong or lanceolate, sessile or nearly so, 1-2 in. long, obtuse or acute: corymbs several-fl.; sepals usually lanceolate-subulate; petals 7-8 lines long, bluish or violet-purple.

**longiflora**, Labill. Lvs. lanceolate, entire: fls. greenish yellow, often changing to purple, solitary; pedicels glabrous: berries blue. N. TAYLOR.

**BILLBERGIA** (for the Swedish botanist, J. G. Billberg). *Bromeliaceæ*. About forty tropical American evergreen epiphytal herbs, now much cultivated by amateurs and in fancy collections. A few kinds are well known to florists. A closely allied genus is *Æchmea*, which see for botanical differences.

The fls. are in a spike or spicate panicle, which rises from the center of the rosette of long, spiny-edged, and usually stiff, pineapple-like lvs., showy, with 3-parted calyx and 3 long petals, 6 exserted stamens, thread-like style, and berry-like fr. The colored bracts of the fl.-clusters are usually very showy. Cf. Charles Mez, the latest monographer, in DC. Phaner. Monogr. 9. Species confused: but the artificial arrangement given below may aid the gardener.

554. *Billbergia scandens*. ( $\times \frac{1}{4}$ )

Billbergias can be cultivated best in greenhouses, planted in pans, pots, wooden cribs, or wire baskets, with loose, light material about their roots, such as pieces of charcoal, roots of very fibrous plants, or fern roots and sphagnum moss, and such material. They demand little water at the roots in winter, and nothing but light sprinkling over the foliage is required to keep them alive during that time. But in summer, when the heat is great and they are making their growth, they can withstand an abundance of moisture at the roots as well as at the top, most of the time holding water in the funnel-like center or body of the plant. They usually produce their conspicuous showy bloom in the spring, when moisture overhead or sprinkling should be withheld in order to prolong the beauty of the flowers. They require at night a temperature of 50° to 75°, but, of course, can stand any amount of heat in summer. Billbergias, like all other bromeliads, make very good house plants, and they will thrive exceedingly well in a living-room temperature. They love plenty of light and sun. All first-class private garden establishments should have at least a few of this class of plants.—They are propagated best from suckers or sprouts, which arise from the base of the old plant, usually after it has bloomed and performed its functions. The old plant then gradually deteriorates, sending out two to five young plants from its base. These can be taken off as soon as they are hardy and substantial enough, and can be mounted or potted into the same kind of material. Then, suspended in the greenhouse, conservatory, or window for an exhibition, they thrive best.—Besides their beautiful and attractive flowers, billbergias have very handsome foliage, which is of a tough and leathery texture. Billbergias, æchmeas, and the like, are natives of the tropics, and, therefore, require a warm temperature. Æchmeas are usually larger than billbergias and tillandsias. (H. A. Siebrecht.)

A. *Peals curling spirally after fl. expands.* (*Helicòdea*.)

**zebrina**, Lindl. (*Bromelia zebrina*, Herb. *Æchmèa zebrina*, Hort.). St. very short, or none: lvs. sheathing, deep green, with blotches and zones of gray-white, strongly spine-margined: fl.-cluster loose, long and drooping; fls. green or yellow-green, the stamens becoming long-exserted; bracts salmon or rose, long-lanceolate. S. Amer. L.B.C. 20:1912. B.M. 2686.

**decòra**, Poepp. & Endl. (*Helicòdea Baraquiniana*, Lem.). Differs from the last in having longer petals,

denser spikes and longer bracts: lvs. 8-10, from 1-2 ft. long, mealy, white-blotched and banded. Brazil. I.H. 11:421. B.M. 6937.

AA. *Petals not spirally twisting.*

B. *Infl. nodding.*

c. *Fls. in panicles.*

**speciosa**, Thunb. (*B. amana*, Lindl. *B. pallida*, Ker). Lvs. strap-shaped, connivent, and forming a tube at the base, 1-2 ft. long, somewhat spine-margined, green above and lepidote and somewhat striped on the back: fl.-cluster large and loose, drooping; bracts rose; fls. pale green or whitish, tipped with blue. Brazil. —An old and well-known species.

cc. *Fls. in racemes.*

**nütans**, Wendl. Stemless, stoloniferous: lvs. linear and long-pointed, 1-2 ft., distantly small-toothed, finely striate on the back: fls. 4-8, in a loose, drooping raceme; petals green, blue-edged; bracts lanceolate, red. Brazil. B.M. 6423. Gn. 32, p. 107.

**Morélii**, Brongn. (*B. Moreliana*, Hort. *B. Wetherellii*, Hook.). Lvs. short, 1-1½ ft., with few weak spines, wide, glabrous and green: fl.-cluster exserted and drooping, with showy, pointed red bracts, the rachis woolly; fls. with red sepals and purple-limbed petals. Brazil. B.M. 4835. J.F. 2, pl. 138. —Very showy.

BB. *Infl. erect.*

c. *Fls. red.*

**thyrsoides**, Mart. Lvs. 1-2 ft., broad-ligulate, spine-margined, concave on upper surface, green above and paler beneath, abruptly acuminate: fl.-cluster shorter than lvs., farinaceous, densely red-bracted; fls. numerous, bright red, petals reflexing. Brazil. B.M. 4756. J.F. 3, pl. 267. —Showy. Runs into several varieties, some of them with purple-tipped fls. (as vars. **splendida** and **fastuosa**, André, R.H. 1883:300). *B. splendens*, Hort., is evidently one of the forms. Species too near the next.

**pyramidalis**, Lindl. (*Bromelia pyramidalis*, Sims. *B. Croyiana*, De Jonghe). A foot high: differs from the last in having more gradually acuminate lvs., which are more strongly and distantly toothed and whitish, or even banded on the back: fl.-cluster less farinaceous, broader and looser, the fls. less numerous. Peru. B.M. 1732.

cc. *Fls. purple.*

**vexillaria**, André. Fig. 555. Hybrid of *B. thyrsoides* and *B. Morelii*. Fls. purple; lower bracts long-pointed and red; spike erect, exceeding the lvs. R.H. 1889:468.

**vittata**, Brongn. (*B. Leopoldii*, Hort., not Morr.). Vigorous, 2-3 ft.: lvs. long and large, concave above, recurved at the summit obtuse, or abruptly pointed, red-spined, cross-banded on the back: fl.-cluster loose and nodding, shorter than the lvs., red-bracted; fls. deep blue, with recurving limbs. Brazil. Gn. 32:106. R. H. 1869, p. 87.

**Liboniana**, De Jonghe. Small, 1-1½ ft., produc-

ing runners: lvs. long-linear or strap-shaped, spiny, very sharp-pointed, concave and green above and whitish-mealy below: fl.-cluster erect or nearly so, rather slender, the bracts not prominent; fls. with red sepals and erect blue petals. Brazil. B.M. 5090. F.S. 10:1048. J.F. 2, pl. 197.

In the American trade the following names have been used: *B. clavata longifolia*, once offered by Pitcher & Manda, is probably an *Æchmea*—*B. fasciata*=*Æchmea fasciata*.—*B. máxima*=(?).—*B. ornata*=(?).—*B. Quesneliana*=*Quesnelia*.—*B. rhodocyanea*=*Æchmea fasciata*.—*B. stricta*=(?).

Any of the following may be expected to appear in the American trade at any time: *B. andegavensis*, Hort., is *B. thyrsoides* × *Morrellii*: fls. red and blue.—*B. Bakeri*, Morr. (*B. pallescens*, Baker). Fls. greenish, tipped purple. B.M. 6342.—*B. Breuteana*, André (*B. pallescens* × *vittata*), has reddish, purple-limbed fls. R.H. 1885:300.—*B. Brantii*, Hort. (*B. Bakeri* × *decora*). Fls. greenish, bracts red.—*B. Enderi*, Regel. Small: fls. very deep blue; bracts coral-red. Brazil.—*B. Forgyana*, Hort. Lvs. large with bands of white on a green ground. G.C. III. 33:258.—*B. iridifolia*, Lindl. Fls. red and yellow, blue-tipped. Brazil. B.R. 1048.—*B. Liétzei*, Morr. Fls. and bracts rose. Brazil.—*B. nobilis*, Bull. Cat. Bracts cerise-carmine, petals green, curling spirally after flowering: lvs. barred.—Perhaps only a form of *B. decorata*, Poepp. & Endl.—*B. Portena*, Brongn. Fls. green, the petals rolling spirally. Brazil. B.M. 6670.—*B. Sanderiana*, Morr. Fls. green, tipped blue. Brazil.—*B. Saundersii*, Bull. Fls. greenish, tipped blue: lvs. striking, green above, reddish beneath, white-blotched and red-spined. Brazil. Gt. 39:1316.

GEORGE V. NASH.†

**BILSTED**: *Liquidambar*.

**BILTIA**: *Rhododendron Vaseyi*.

**BINDWEED**: Name applied to various twining weedy plants, particularly to various kinds of *Convolvulus*.

**BIOPHYTUM** (life-plant, some of the species being sensitive to the touch). *Oxalidaceæ*. Oxalis-like perennial herbs, sometimes grown under glass as curiosities: lvs. abruptly pinnate, with many lfts.: valves of caps. separating to base. There are about 20 species in Trop. Asia, Afr. and Amer. **sensitivum**, DC., with 6-15 pairs of lfts., has lvs. that contract at the touch: fls. small, yellow: 6 in. Generally spread in the tropics. B.R. 31:68 (as *Oxalis*). **B. Föxii**, Sprague, is a recently described species from Peru, with st. 2 in. high and bearing 8 lvs. at the apex in a whorl: lfts. 3-6 pairs: fls. white.

**BIOTA**: *Thuja*.

**BIRCH**: *Betula*.

**BIRD CACTUS**: *Pedilanthus*.

**BIRD-OF-PARADISE FLOWER**: *Strelitzia*; also *Czsalpinia Gilliesii*.

**BIRDS**. The horticulturist has the opportunity to avail himself of a mighty band of helpers in the birds. It seems not to be understood that it is perfectly possible for a bird to be eating something useful to man at some particular moment, and at the same time to be spending by far the greater part of its time eating things that are harmful to man, for which service it should be carefully protected. Very thorough studies of the food of birds have proved that the great majority are helpful to one who raises crops. Most birds are beneficial most of the time, and very few have no redeeming traits in this regard. Moreover, if useful birds are protected at all times, so as to encourage the natural increase, they will do their part in an emergency, such as an invasion of insects. Aside from these economic reasons for bird-protection is the gaia that comes from their presence as attractive and interesting objects in nature, as much to be desired as blossoms and gardens.

It is said that there is less need of birds now that insects are being destroyed by arsenical sprays. This is perhaps to some extent true, but even in fruit-plantations the birds are still effective; and there are hosts of insects that are not effectively held within bounds by the sprays. Spraying will never take the place of birds.

*Protection of birds from their enemies.*

Birds should be both protected and attracted. Men and boys with guns and sling-shots, cats, and the Eng-

555. *Billbergia vexillaria*.

lish or house sparrow are the most common enemies or destroyers of birds. The red squirrel, weasel, crow, and shrike are destroyers as well, but they seem to be regulated naturally, although frequently one may interfere to good effect, particularly in the case of squirrels in parks. But man, the cat and the English sparrow should be controlled. Our boys can be educated to protect the wild birds. It is being done in many homes and schools. As soon as a boy learns the interesting habits of the common birds he loses the desire to kill, and he prefers to protect and observe. A bluebird or wren nesting on the premises will do more than all the laws to correct the lawlessness of boys.

556. Pouring the food on the "food-tree."

Experience shows that one must deal with the house or English sparrow, if one is to win back our insect-eating birds in any great numbers. The increase of other birds is in inverse ratio to the decrease of English sparrows. However, not everyone should be allowed to take part in the warfare against them. Schoolboys and inexperienced men make too many mistakes in trying to destroy them and their nests; and the taking of the eggs from the nest seems too much like an outrage on the instinct of motherhood, to be tolerated. The English sparrows should be kept within bounds as to numbers. They can be kept in check by the use of poisoned grain in winter. Some persons object to this practice from sentimental reasons, but it is no worse to despatch house sparrows than mice, prairie dogs, insects or other pests; and if man does not keep the sparrows within limits, they will destroy or drive away other birds. A certain number of house sparrows is desirable in winter, particularly in towns where there are few other winter birds, but they should not be allowed to become nuisances. See page 507.

It has been estimated that a cat destroys on an average about fifty song birds in one season. A new attitude toward cats is needed. They should no more be allowed to roam at will than should chickens or goats. All cats away from home are trespassers, and should be so regarded; they should fall to the care of a bird-warden. Bird-killing cats should be destroyed or kept within doors.

557. The "food-stick."

To attract birds, it is of course necessary to win their confidence. They must feel comfortable and secure. They must be aided to live through severe winter weather, and they must have adequate nesting-places and drinking-places. Measures to secure these ends have been put to the test and found to be genuinely satisfactory.

#### Feeding birds in winter.

Many birds perish for want of food in every severe winter. They digest their food so quickly that lack of it for a few days results in death. The real necessity is in the time of blizzards and continued cold, when they cannot find their natural food.

For insect-eating birds, suet and fat pork or a split bone may be fastened to the trunks of trees by means of wire netting and stout cord. Woodpeckers, nut-hatches, and chickadees will be attracted. The netting prevents crows, jays and squirrels from carrying off the whole piece of food

Seed-eating birds may be fed crumbs, nuts, millet, chaff, sunflower seeds, squash seeds, and various grains, including corn; also any kind of poultry-food, and even dog-biscuit. These materials may be placed on the ground after removing the snow, but should be protected to prevent waste. Many a bob-white has survived a heavy snowstorm by coming regularly to such a place. All kinds of sparrows, juncos, and snow buntings are among the birds that are attracted by such supplies.

Many ways for feeding birds near the residence have been more or less successful, depending largely on the prevalence of the English or house sparrows. The tree-shelf, window-shelf, moving shelf or counter, and the coconut filed with pork and kernels of nuts, are among the most useful devices.

In Germany, Baron von Berlepsch has experimented effectively in the winter-feeding of birds, with the idea of securing the protection of the food, and of making it accessible at all times to all birds. On his estate at Seebach he uses the "food-tree," the "food-stick," the "food-house" and the "food-bell," all of which were devised after many years of study of the habits of birds. The food-tree (Fig. 556) imitates a coniferous tree closely covered with insect eggs and larvæ. A mixture of hot liquid food which hardens as it cools is poured upon the tree. This food consists of white bread (dried and ground), meat (dried and ground), hemp, millet, sunflower seeds, and other seeds mixed with water. The food-tree is especially interesting to children and has brought good results in the study of winter birds. The food-stick (Fig. 557) is merely a part of a branch with six holes in which the food mixture is placed at intervals. The food-house (Fig. 558) is the most satisfactory of all ways of feeding. It consists of a roof on four corner posts with upper and lower food-tables, the lower being used only until the birds have discovered the upper table. Below the roof a strip of glass is fixed from post to post. This is very important to protect the food from the weather and also to admit light. The food-bell (Fig. 559) is a device for making hemp seed always accessible to the birds. It is very popular, except with the English sparrows. It may be placed on trees or buildings.

558. A "food-house" that can be easily made.

559. Section of "food-bell."

a, food-dish; b, tube; c, food reservoir; d, metal bell.

#### Nesting-houses.

The birds that naturally make their nests in holes in trees are the ones that have been induced to build in artificial houses. Accordingly, the most successful houses are those that somewhat resemble a hollow limb, although great success has been attained with board houses, and other styles, as gourds, and coconuts, and even tin-cans. In fact, some bird will adapt itself to almost any kind of house, provided cats, red squirrels and English sparrows are kept away.

A most satisfactory cat-proof box for a bluebird can be made of weather-stained boards, if the following

precautions are taken: The hole should be well near the top with no perch near; the roof should slope from the back toward the front and should project about three inches. If the box is deep, the young bluebirds find it difficult to leave the house until they are strong and able to care for themselves, and this is a great advantage. The roof prevents rain from beating in, and keeps the cats out. From whatever direction the cat may attempt to reach the hole, the projecting roof stands in the way of reaching the nest. Twelve by 6 by 6 inches are good dimensions for such a house. It should be placed 8 to 15 feet above the ground.

The house wren is the easiest of birds to attract. It will easily appropriate any little house if the English sparrow does not interfere. A good size is 7 by 5 by 5 inches, with the hole only as large as a 25-cent piece. It should be placed 6 to 8 feet from the ground, with the long axis of the box backward. The wren has the habit of filling the front of the house with sticks and leaving a hollow in the rear for the eggs. The hole should be in the upper half of the box. The middle of April is not too early to place it, in the northern states, although houses put out late may attract for the second brood. It is well to make the house so that it can be opened, to permit of its being cleaned for the second brood, for the wren will choose a clean house if it can find one.

The purple martin is an attractive neighbor. Unlike the wrens, which will not nest near one another, the martins are gregarious, so that the houses should have a number of compartments, each part 9 by 11 inches, with entrance  $2\frac{3}{4}$  inches across. The house should be placed 15 to 20 feet above the ground. To prevent English sparrows from building before the martin arrives in the spring, the openings should be covered until April; or better, the house may be taken down in the fall and put up again in April.

Woodpeckers may be induced to live in houses. The opening should always be circular and with an upward slant; the bottom of the nesting cavity should be gourd-shaped and end in a pointed trough within which a few shavings are placed; and the inner

561. Berlepsch Nesting-box.

562. Longitudinal section of Berlepsch's nesting-box.

walls should be roughened somewhat to allow the young birds to cling more easily. Of the 10,000 or more of these houses tried in parts of Germany, more than 90 per cent are occupied.

#### Drinking- and bathing-places for birds.

Birds need free access to water. If a brook or pond is near by, no more is necessary; but, otherwise, special provision should be made. The presence of water is a great factor in inducing birds to nest in a given locality.

There are many kinds of bird-fountains, but the chief characteristics are that the water be shallow, that the edge of the container be not slippery, and that they be placed where there are no hiding-places for cats. Most interesting styles have been devised, varying from constructions of natural rocks holding little pools, with wild flowers and ferns close by, to those made of flower-pot saucers, or of special pans, placed safe from molestation. School children are readily interested in the pla-

560. The Hilbersdorfer food-house.

cing of bird-fountains and in watching the birds that come to drink and to bathe.

#### Nesting-places for birds that build in the open.

Birds breeding in the open nest in bushes and trees and on the ground, and among reeds or in banks. These comprise by far the larger class, and yet these birds are finding it more and more difficult to secure nesting-places. One cuts off hedges along roads and fences, cleans the pastures and meadows, digs away the banks and seals up the roofs of barns with little thought of the birds that would like to nest there.

While all trees provide more or less shelter for birds, the conifers are most useful for this purpose. It is practicable so to plant as to have wild fruits for birds at all times of the year, and especially in cold winter days, and perhaps during the time in which one wishes to protect cultivated fruits. It seems to be agreed that the best single tree is the mulberry, either the white or the Russian. The fruiting season is long, and the trees are easily grown. Four good plants are: early sweet cherry, Juneberry or shadbush, mulberry, Virginia creeper. Probably more birds visit these plants than any others. Many other shrubs and herbs are of great value, as elder, black cherry, rasp-

berry, blueberry, dogwood, pokeberry, and mountain-ash. Many growers protect their cherries and strawberries with mulberry and shadbush; or they plant a sweet early variety of the given fruit, to be left unpicked especially for the birds. Elder, Virginia creeper, and black cherry will serve as protectors for grapes. Raspberries and blackberries may be protected by mulberry, chokecherry, and elder.

Germany recognizes Seebach as the great bird experiment station. Repre-

sentatives of many states and countries have visited the place, making effective observations of methods. For these students, special winter courses in bird-protection have been arranged, including not only theory

but practical instruction. They find many acres of wood, thicket, and park made attractive to birds, with luxuriant undergrowth about the trees, special care as to the species, the shrubs specially pruned (Figs. 565, 566); hundreds of nesting-houses; food-houses and food-bells in various situations for winter-feeding. In the spring of 1905, the trees of the Hainich wood, south of Seebach, were stripped bare by the larva of a little moth (*Tortrix viridana*), whereas the wood at Seebach with its nesting-boxes was untouched. At a distance of a little more than a quarter of a mile the first traces of the plague were apparent.

#### THE ECONOMIC IMPORTANCE OF FAMILIAR BIRDS.

Woodpeckers are especially fitted for the care of trees. The downy is the most useful woodpecker. It is the bird of the old orchard, preferring neglected trees, under the scales of which the codling-moth larva lies during the winter. It has been known to visit as many as 181 woodland trees between 9:40 A.M. and 12:15 P.M., making, meanwhile, twenty-six excavations for food, most of

563. Nesting-box.

564. Nesting-box.

565. One-year-old whorls recently pruned, to provide nesting places.

566. Old whorls recently pruned.

which exposed galleries of wood-boring ants. The hairy woodpecker (Fig. 567) is equal to the downy in importance, being fond of wood-boring beetles and wood-boring ants. Its large size and strong beak give it much power in drilling deep. A few ears of corn and a little suet will attract him. He is becoming less common than the other woodpeckers. The flicker is much misunderstood. Ants constitute about 40 per cent of his food, and he eats, also, many beetles, grasshoppers, and caterpillars, besides some wild fruit. The

567. Hairy woodpecker.  
(Length 9 in.)

red-headed woodpecker is especially fond of beech-nuts and acorns. It stores them for winter use. In its storehouse are often to be found quantities of dried grasshoppers also. It is an irregular permanent resident in the East, but in the West it migrates regularly. The yellow-bellied sapsucker (Fig. 568) doubtless does considerable harm; in fact, it is responsible for most of the objections to woodpeckers in general. Whether the good done in destroying insects in the breeding season balances the harm done in sucking sap is an open question. The sapsucker drills holes in the trunks of many of the most valuable trees, as sugar maple, birch, pignut hickory, pine, apple, mountain-ash, beech, and others. The death of the trees may result not only from the loss of sap, but from the work of borers that deposit eggs in the holes. If the sapsuckers are to be destroyed, care must be taken not to kill the downy woodpecker at the same time. Fortunately, the sapsuckers are resident in fruit sections for only a short time in the spring and autumn. In their northern breeding-grounds they destroy many noxious insects. The red-bellied woodpecker annoys growers of Florida by its fondness for orange juice. Else-

where it is of much value as a destroyer of ants and beetles and other insects.

The chickadee is a permanent resident. Many other birds seek their company, so that one has but to follow them as they rove to find many smaller birds. This is particularly true in spring and fall, when the warblers are in migration. In an experiment in Massachusetts, chickadees were attracted to an orchard in the winter by means of suet fastened to the trees. The birds destroyed multitudes of eggs of the fall canker-worm moth. The conclusion was reached that one chickadee would destroy in one day 5,550 eggs; and in the twenty-five days during which the canker-worm moths crawl up the trees 138,750 eggs might be taken by one chickadee. Chickadees readily accept a nesting-box.

The white-breasted nuthatch is the constant companion of the chickadee and the downy woodpecker. It takes from the bark great numbers of eggs of canker-worms, and many of the oyster-shell bark-louse, and even the hairy caterpillars of the gypsy moth. It is easily attracted by suet and will often eat crumbs as well. The red-breasted nuthatch, a smaller bird with dull reddish breast, comes from the North in September, spending the winter in attending to tree-trunks, and returning North in the spring.

The brown creeper, with its long curved beak, rounded back, and stiff tail, is especially valuable for service among shade trees. It starts at the base of the trunk, ascending spirally, quietly investigating crevices as it goes.

558. Yellow-bellied woodpecker, or sapsucker. (Length  $8\frac{1}{2}$  in.)

The slate-colored junco, or snowbird, comes from the North in autumn and remains all winter, busy all the time in reducing the number of weed-seeds. The snowbirds rove in little flocks, and easily respond to seeds and crumbs put in any open place. In the North the junco destroys many insects, for the young eat insect food only.

The American robin (Fig. 569), (which is a very different bird from the robin of Europe), is protected by law in all of the United States excepting seven of the southern states. The National Association of Audubon Societies is making efforts to secure the passage of laws better calculated to protect it. An examination of the

stomachs of 330 robins showed that vegetable food constituted about 58 per cent of the contents. Of this, 47 per cent was wild fruit, with only a little over 4 per cent cultivated fruit. The United States Department of Agriculture has shown by recent investigation that in the South the robin is essentially an insect-eating bird. The robin is the great enemy of the white grub, the young of the May-beetle or June-bug. The robin is an inveterate devourer of earth-worms in spring. Although the earthworm is useful to the soil, if it were allowed to increase naturally, with no interference by the birds, it would rapidly become a pest. The favorite food of young robins is the cutworm, and this is important, since there are frequently two or three broods of robins in a season and a young

569. The American robin. (10 in.)

robin's appetite is nearly insatiable. The cutworm feeds at night and is going back to its hole at daybreak, when the robin intercepts it. One may prevent the robin from eating cherries by planting trees that are in fruit at the same time, as the Russian mulberry, and the shadblow and wild cherries, or even a cheap variety of cherry. The strawberry-grower may plant a variety of inferior strawberries to attract the robins from his choice fruit.

The bluebird (Fig. 570) destroys quantities of cutworms and other caterpillars. In August and September grasshoppers constitute more than 60 per cent of its food. It is fond of wild fruit, especially berries. Unfortunately, the bluebird is becoming uncommon.

The sparrows are among the most valuable birds to the farmer. The food of the native sparrows, as a family, consists of 25 to 35 per cent of vegetable matter, and 65 to 75 per cent animal matter. Young sparrows are almost entirely insectivorous until they leave the nest. Many sparrows rear two broods in a season. As soon as the insect season is over, they turn their attention to weed-seeds, of which Beal estimates that tree sparrows alone eat 875 tons in one season; and even this estimate may be too low. Forbush found, among other things, that a song sparrow, even after it had been eating seeds for about an hour before he began to count, ate 154 seeds in ten minutes and forty-five seconds. Song sparrows eat the seeds of such troublesome things as chickweed, purslane, sorrel, dandelion, and dock; also pests like plant-lice and cutworms, and caterpillars of the brown-tail and gypsy moths. The field sparrow (Fig. 571) is smaller than the song sparrow and very shy. It scarcely comes into our towns, but its clear trill from the fields suggests the warm days of late spring and early summer. It has been seen to eat May-beetles, leaf-hoppers, saw-flies, spiders, ants, and some earthworms. In the field it prefers weed-seed to grain. The chipping sparrow has the distinction of being the most useful sparrow, having an astonishing list of services to its credit. In the spring it feeds largely upon small caterpillars, as the gypsy, brown-tail, and tussock moths. It destroys at least three species of caterpillars on the cabbage; it is fond of wild cherries, chickweed seeds

570. Bluebird. (7 in.)

and seeds of ragweed, smartweed and many other weeds, including dandelions and the crab-grass of the lawn. The vesper sparrow is nearly as abundant as the song sparrow. It eats quantities of grasshoppers and beetles and weed-seeds. The English sparrow was introduced into the United States in 1850 for the purpose of destroying cankerworms and other insects just then becoming numerous. At first it was received with delight. A very short time, however, showed conclusively that it did more harm than good, and now every locality has its "sparrow problem." The charges against the English sparrow are serious. An investigation in Illinois showed that out of twenty-five stomachs of English sparrows at a time when 30 per cent of the food of the robin, 30 per cent of the food of the catbird, and 90 per cent of that of the bluebird consisted of insects, no insects were found in these sparrows, excepting traces of grasshoppers making perhaps 6 per cent of the food. However, during the first sixteen days of the nestlings' life, 40 per cent of the food consists of caterpillars, 10 per cent of beetles, and 40 per cent of small grains. This is perhaps the best that can be said for the English sparrow. It is so pugnacious that it has driven most of the bluebirds, wrens, and purple martins from the towns, while they themselves do not eat the insects that these birds would eat. Organized warfare against them has been more or less successful. But to

allow the public in general to attempt destroying the nests, poisoning them or shooting them, is running a great risk in the use of guns and poison; and to offer prizes for their nests and eggs is sure to result in the destruction of many nests of valuable sparrows. This work should be done systematically by specially appointed persons at the public expense. In some European cities, there is an official known as the "Sparrow Warden," whose duty it is to proceed energetically against the sparrows.

The house finch, or linnet, has been the source of much complaint on the part of the fruit-growers of California, so that the investigations of the Biological Survey were of great interest. It appears that its claim to protection is in its enormous consumption of the seeds of weeds, as well as for its esthetic value,—for it certainly is a trim little bird and a good singer. Inasmuch as the linnet's food has been proved to be 86.2 per cent weed-seeds, and since examination of the contents of many stomachs shows that fruit is far from being its principal article of diet, many Californians protect the bird and plant shrubs and trees to attract them away from the fruit. These birds are fond of elderberries and many other wild fruits.

571. Field sparrow. (5½ in.)

The cedar waxwings or cherry-birds (Fig. 572), go in small flocks in search of food. Their fondness for cedar berries has given them their name although they have a wide range of food. In early summer they feed almost exclusively on insects and become expert flycatchers. Unfortunately, they have a bad reputation among fruit-growers because of their fondness for cherries. It has been shown, however, that they abundantly pay for the cherries taken. From an orchard infested with canker-worms, the stomachs of seven cedar-birds were examined, all of which were full of worms, averaging 100 to each. It was estimated that this flock would destroy 90,000 of the pests if they stayed in the orchard a month. At Washington, 152 stomachs of cedar-birds were examined showing that 74 per cent of the food consisted of wild fruits, 13 per cent of cultivated fruits, 5 per cent of which was cherries. The remainder consisted of grasshoppers, bark-lice, and beetles, among them the elm-leaf beetle.

The Carolina wren adapts itself to civilized conditions, and often nests about houses and farm buildings, as well as in old logs and tree-trunks. It is an eminently useful species, destroying great numbers of beetles, ants, weevils, especially the boll-weevil, which it destroys during its period of hibernation. Like its relative, the house wren, it may be attracted by nesting-houses. It is not migratory and may be heard all the year round from the Gulf north to Connecticut and Illinois. The house wren (Fig. 573) will occupy almost any little box, provided it be water-tight. The English sparrow will do its best to drive the wren away, but with a small opening the wren is safe and will usually win in the contest. The diet of the wren is mainly insectivorous, consisting of grasshoppers, ants, beetles, grubs, spiders, and hairy caterpillars. Many a fruit tree has been saved from the ravages of the tussock moth caterpillar by a family of wrens in the vicinity. Wrens gather spiders' egg-sacs full of eggs, putting them inside the house on the wall, ready for the first meal of the young birds.

The catbird (Fig. 574) is fond of fruit. The robin is often blamed for the deeds of the catbird. Inasmuch as the nestlings eat 95 per cent animal food, mainly insects and spiders, it is far better to

572. Cedar-bird, or cedar waxwing. (Length 7 in.)

plant fruit trees especially for the catbirds than to destroy them on account of their fruit-eating habits. In case of insect outbreaks, the catbird attacks gypsy, brown-tail, canker-worm, and tent-caterpillars.

The attacks that the Baltimore oriole makes on the cherries, grapes, and the pea-pods, are more than paid for by its destruction of insects. Tent-caterpillars and other hairy larvae that many other birds will not touch are eagerly eaten by it. The oriole does not swallow the whole caterpillar, but carefully removes a small portion of the inside. The orchard oriole is a related bird. Investigations in the cotton fields of Texas and Louisiana show that nearly a third of the specimens examined contained remains of the cotton-boll-weevil. Like the Baltimore oriole, it is mainly insectivorous in its diet and destroys a great many injurious species.

Blackbirds are of several kinds. The purple grackle and the bronzed grackle are together known as crow blackbirds (Fig. 575). Their food has been thoroughly studied. An examination of 2,258 stomachs showed that corn is consumed every month. At the same time, were found insects, spiders, myriapods, crawfish, earthworms, sow-bugs, hairsnakes, snails, fishes, tree-toads, salamanders, lizards, snakes, birds' eggs, and mice. Of the 48 per cent of animal food, 46 per cent consisted of insects. Of these, beetles were present in the greatest numbers. Many stomachs were crammed with large white beetle grubs. Often more than thirty grasshoppers were found in a single bird. Young blackbirds are fed on insect

food entirely. They flock to caterpillar outbreaks. Many cases are reported in which fields have been entirely freed of sudden growths of grasshoppers and crickets. The red-winged blackbird has a bad reputation and is unprotected in many states. These birds appear early in the spring and remain late in the fall. They feed their young on insect food. Examinations of the stomach contents of the adults show that about seven-eighths of the red-wing's diet is made up of noxious insects and weed-seeds. The slaughter of blackbirds that occurred in the West during the twelve years previous to 1877 was in reality a national loss. The cowbird was named from its habit of accompanying the cattle and eagerly picking up the insects which are started up as they feed. The cowbird's food habits are on the whole beneficial, since it eats many insects and weed-seeds. The fact, however, that each young cowbird is raised at the expense of several more valuable birds (by appropriating their nests) makes it too costly. Brewer's blackbird is the western representative of the eastern rusty blackbird. Examination of 146 specimens gave the following facts: (1) Grasshoppers constitute more than half of its animal food; (2) more than 88 per cent of the vegetable food is grain, which is freely eaten at all seasons, even when insects are abundant; (3) seeds of harmful weeds are eaten sparingly. On the other hand, it does not attack fruit, which is an important point in a California bird. The yellow-headed blackbird, while wintering in the South, wanders over the country in quest of scattered and wild grain, weed-seeds, various insects, grubs and worms, and does little harm. In the spring, however, the birds congregate at their nesting-haunts and supplement their insect and waste-seed diet by various grains planted by the farmer of the Great Plains, and they are deservedly regarded as a great problem. In the plowing season, they follow the plow and greedily devour the earthworms and insects turned out, also the white grub, the cockchafer, and grasshoppers, the last forming a large part of the food of the young. So far as it has gone, the published work of the Biological Survey on the food of the yellow-headed blackbird, indicates that on the whole the good done by this bird somewhat overbalances the harm.

573. House wren. (4¾ in.)

The meadowlark destroys quantities of grasshoppers, cutworms, beetles, chinch-bugs, crane-flies, and "thousand-legs," where it takes only a few useful insects and a little scattered grain. In summer, 99 per cent of its food consists of insects, and in winter it takes many weed-seeds. The kingbird (bee martin) (Fig. 576) is esteemed by agriculturists for its pugnacious disposition in driving off crows and hawks. Ninety per cent of its food consists of flying insects. It belongs to the family of flycatchers, of which the phoebe, the wood pewee and the great crested flycatcher are conspicuous members. They all obtain their food on the wing, darting off frequently from some chosen limb and back again. Bee-keepers have contended that the kingbird catches and kills honey-bees. In an investigation of 281 stomachs, only fourteen contained any remains of bees, fifty in all, of which forty were drones, four were workers, and six undetermined. At the same time, nineteen robber-flies were found, which more than compensated for the four workers. It is probable that kingbirds do eat a few bees, mostly drones, but they certainly also protect bees from insects that prey upon them.

Of swallows, there are five species in Eastern North America that one may expect to see: the barn swallow, the cliff swallow, bank swallow, tree swallow, and the purple martins. All of them do valuable work in clearing the air of insects, but the horticulturist will do well to encourage especially the purple martin. It feeds largely on some of the greatest pests: rose-beetles and May-beetles, the striped cucumber-beetle, as well as house-flies and flies that trouble cattle and horses.

574. Catbird. (Length 9 in.)

The blue jay (Fig. 577) has been shown by investigation to be beneficial as a rule, and that, except in cases in which it is discovered actually engaged in doing harm, it should be protected. Nearly 300 stomachs showed that the real food is composed of about 25 per cent animal matter, and about 75 per cent vegetable matter. The animal matter is, chiefly insects, with a few spiders, myriapods, snails, fish, salamanders, tree frogs, mice, and birds. Remains of birds were found in only two out of 300 examined. Only three contained eggs of small birds. Apparently its nest-robbing propensities are not so general as is supposed. In August, the percentage of insects reaches 66 per cent. They prefer mast, or seeds of trees and shrubs, to corn or any other vegetable food. Corn is the only vegetable food of which the farmer suffers any loss, and here the damage is small. The California jay is a problem. Very careful and extensive investigations of the bird have resulted in the conviction that it has many more bad qualities than good. In fact, it has few redeeming virtues. Something may be said in its favor, from the esthetic side, as he is a handsome bird, and people interested in country life would no doubt miss his presence. Beal says that if they could be reduced to a fourth or a half of their present numbers, the remainder would probably do no serious harm. They eat very few insects, and destroy many eggs and young birds. They eat grain from the newly sown fields, but do not pull it up after it has sprouted, so that this is of minor importance. They are insatiable fruit thieves, not only eating enough for present need, but storing it away for future use.

The black-billed and yellow-billed cuckoos are valuable to the forester, orchardist, and the farmer. They feed mainly on the medium-sized and larger caterpillars and grasshoppers, as well as many other insects. In May and June, when the tent-caterpillars are defoliating forest trees, these insects constitute half of the cuckoo's food. One stomach was so full that the bird had evidently

study. From 353 stomachs of bush-tits collected in every month, less than 1 per cent of the food was found to consist of fruit, and over four-fifths consisted of insects and spiders. The largest item was plant-lice, or bark-lice, or scale insects. Several stomachs were entirely filled with them. The stomachs of eight nestlings contained pupæ of the codlin-moth. It would probably be difficult to find a more valuable bird than the bush-tit. The birds live in flocks nearly nine months of the year.

The black-headed grosbeak has been the subject of complaint by the Pacific coast fruit-growers, for it is fond of figs, cherries, and berries. However, it eats many insects that cost the horticulturists much annoyance. The codlin-moth, canker-worm, flower-beetles, and scale insects are among its favorites. An examination of 226 stomachs, the majority of which were collected in California, shows that during the six months of its stay in that state the bird consumes about 34 per cent of vegetable food, and 66 per cent of animal food, with a distinct preference for the black olive-scale, one of the most destructive insects of the coast. This insect alone constitutes a fifth of the entire food. To put it graphically, the black-headed grosbeak, for every quart of fruit eaten, eats more than three pints of black olive-scales, and more than a quart of flower-beetles, besides a generous supply of canker-worms and pupæ of codlin-moths.

The mourning dove has scarcely an equal as a weed-eradicator. The Biological Survey has shown that of 237 stomachs examined, over 99 per cent of the food consisted of seeds. Wheat, oats, rye, corn, barley, and buckwheat, were found in 150 of the stomachs and constituted about 32 per cent of the whole food. Three-fourths of this however, was waste grain picked up from the fields after the harvesting was over. Wheat was the favorite grain, and about the only one taken when in good condition. Corn, the second in amount, was damaged grain, taken after the harvest. The principal and almost constant diet, however, is weed-seed eaten at all seasons, constituting 64 per cent of the annual food-supply and showing little variation in any month. Three mourning doves which were examined had destroyed 23,000 prospective weeds. Yet they moved silently, and no one knew of their work.

The dickcissel, or black-throated bunting, is common in field and prairie in the Middle West, where its plaintive song gives variety to the silent days of July and August. Its food is more than half grasshoppers and crickets, and the remainder seeds of weeds and grasses. In some localities it is known as the "little meadowlark," its color being like that of the meadowlark, even to the black locket on a breast of brilliant yellow.

The cardinal and his mate are indeed a conspicuous pair. They are known as cardinal grosbeaks, redbirds, crested redbirds, and Virginia nightingales. They are most abundant in the southern United States, although frequent records show the limit of their range to be approximately a line drawn from New York City westward to southern Nebraska, and thence south to Texas. The cardinals' food is varied, consisting of seeds of numerous plants, especially those of rank weeds and grasses. The large and powerful beak readily breaks into large seeds, as corn, wheat, rye, and oats. It eats great quantities of adult beetles, especially rose-beetles; also crickets, grasshoppers, flies and ants. It enjoys grapes, berries,

576. Kingbird. (8½ in.)

575. Crow blackbird, or purple grackle. (Length 12 in.)

devoured the whole tent-colony. It is impossible to over-estimate the value of the cuckoo's work. The cuckoo of Europe is a bird of very different habits.

The common crow is a subject of much dispute. In a report of the United States Department of Agriculture, 1895, the evidence for and against the crow is clearly summarized as follows: (1) Crows seriously damage the corn crop and injure other farm crops, usually to a less extent; (2) they are very destructive to the eggs and young of domesticated fowls; (3) they do incalculable damage to the eggs and young of other birds; (4) they do much harm by the distribution of seeds of poison-ivy, poison sumach, and perhaps other noxious plants; (5) they do harm by the destruction of beneficial insects. On the other hand, they do much good: (1) By the destruction of injurious insects; (2) by the destruction of mice and other rodents; (3) they are valuable occasionally as scavengers. On the whole, it seems that the crow is not to be encouraged, although it need not be altogether exterminated.

The bobolink does nothing but good while it is feeding the young, insects forming about 85 per cent of the food. No fault can be found with him in the North, although he becomes a veritable pest in the South, destroying much rice. The annual slaughter of the "rice-birds" in the South accounts for the gradual decrease in numbers in New England.

An examination of eighty-two specimens of California thrasher shows that vegetable food exceeds the animal in the proportion of 59 to 41. Since it is eminently a bird of the ground, it is surprising to find that in addition to very many beetles, caterpillars, ants and spiders, a great number of bees and wasps were found in the food, also. There were many more wasps than bees. The vegetable food consisted of fruit, poison-oak seeds, and miscellaneous material. The thrasher must be added to the list of birds that assist in the dissemination of poisonous plants. It is not probable that the thrasher will ever become a resident of the orchard.

The western tanager, like the robin, sometimes becomes a nuisance in the orchard. It breeds north of the fruit-growing sections of California, but does injury to the cherry crop on its way north during the migration period. The investigation of the Biological Survey shows that it has a fair right to protection at the hands of the farmer, and even of the orchardist. It is suggested that wild cherry trees planted around cherry orchards may attract the birds away from the fruit.

The California bush-tit has been made the subject of special

577. Blue jay. (11½ in.)

mulberries, cedar-berries, preferring the wild varieties always. These habits, added to the striking beauty of its plumage and of its song, make the cardinal a great favorite.

The mockingbird is omnivorous. While investigating the feeding habit of this remarkable bird, Beal found that in fifty-two specimens 29 per cent of the food consisted of vegetable matter, of which 50 per cent was fruit. The birds' appetite for fruit and

berries in some communities becomes at times so marked that many fruit-growers complain, while others plant more fruit to provide enough for both man and bird. Besides fruit and berries, its food includes the seeds of dogwood, holly, red cedar, and pokeberry. It eats a great many noxious insects, including grasshoppers, beetles, cotton-worms and boll-weevils.

The bird pictures herewith are adapted from Farmers' Bulletin 54, U. S. Dept. Agric. on "Some Common Birds in Their Relation to Agriculture," by F. E. L. Beal.

CORA A. SMITH.

BIRD'S-NEST FERN: *Thamnopteris*.

BIRD'S-TONGUE FLOWER: *Strelitzia*.

BIRTHWORT: *Aristolochia*; also *Trillium*.

**BISCHÓFIA** (for G. W. Bischoff, Professor at Heidelberg early in nineteenth century). *Euphorbiaceæ*. Ornamental tropical tree.

Lvs. alternate, trifoliolate; calyx imbricate; ovules 2 in each cell. The one species is being used to some extent in recent years in the warmer parts of the U. S. It is said to grow freely in sandy soil.

**trifoliata**, Hook. (*B. javánica*, Blume). Toog. A fine tree, with bronze-green lvs.; lfts. stalked; sepals 5; petals none; fr. berry-like. Trop. Asia and Pacific Isls. Hook. Ic. Pl. II. 5:844.

J. B. S. NORTON.

**BISMÁRCKIA** (in honor of Prince Bismarck). *Palmaeæ*, tribe *Borasseæ*. Sometimes referred to *Medemia*. A genus nearly related to *Latania* and distinguished by having only 6 stamens instead of many. Forms a tree 200 ft. high, with a gigantic crown of palmate lvs. with white-streaked petioles and blades 10 ft. in diam.; fr. borne in large, drooping clusters, dark brown, plum-like, 1½ in. diam., with a thin outer shell and a fibrous inner one inclosing a rounded, wrinkled seed 1 in. diam., reticulated like a walnut and ruminated as in the nutmeg. Cult. as for *Latania*, but the winter temperatures should be from 65-70° and summer temperature from 80-90°. G.C. II. 22:596.

**nóbilis**, Hildeb. & Wendl. In young plants petiole convex on the back, channelled above, finely serrate on the ridges above, thinly clothed with tufts of fibrous scales, half as long as the blade; blade blue-green, rigid, 3 ft. in diam.; segms. 20, 2 in. wide, 1 ft. long, apex blunt, obtuse, with a long curved filament from the base of each sinus. Madagascar. G.F. 6:246. F. R. 2:257. Gt. 1221.

JARED G. SMITH.

N. TAYLOR.†

BITTER-SWEET: *Solanum*; also *Celastrus*.

**BÍXA** (S. American name). *Bixaceæ*. A monotypic genus of tropical trees with large, entire lvs. and showy fls. in terminal panicles: lvs. entire, long-petioled, dotted; sepals 5, distinct, imbricate, deciduous, alternating with exterior glands; petals 5. *B. Orellana* is cult. in the E. and W. Indies for the annatto dye prepared from the orange-red pulp that covers the seeds. It is the coloring matter chiefly used in butter and cheese. It is also used in dyeing silks, and preparing chocolate.

**Orellana**, Linn. ANNATTO-TREE. Height 30 ft.: lvs. cordate; fls. pinkish or rose-color. B.M. 1456.—It is rarely grown in northern greenhouses as an ornamental. Cuttings taken from a flowering plant will produce flowering plants of a convenient size. Plants from seed usually flower less freely, and must attain a greater size before flowering.

N. TAYLOR.†

**BLACKBERRY**. Cultivated blackberries are the progeny of several species of the genus *Rubus*. The common garden blackberries are all natives of America, while two little-known but quite distinct forms, the Oregon Evergreen, much grown on the Pacific coast for its fruit and as an ornamental, and the Himalaya, comparatively recently introduced in commercial plantations, come from the Old World. Blackberries are erect-growing perennial plants, bearing black or occasionally whitish fruits which do not separate from

the juicy receptacle. Dewberries are distinguished from blackberries only in being procumbent plants, while raspberries differ chiefly in bearing variously colored fruits that fall from a dryish receptacle when ripe. Blackberries are now largely grown only in North America but they are being introduced in gardens in

other parts of the world, from some of which, notably in New Zealand, they have escaped and have become troublesome field and roadside plants.

The kinds.

There are many forms of blackberries, species, subspecies and varieties with many hybrids and intergradients abounding. At present it is impossible to group the forms with the expectation of a permanent classification. (For a botanical classification see *Rubus*.) The following is the common arrangement of the horticultural varieties (Bailey): (1) The Long-Cluster varieties are probably

578. Wild Blackberry—*Rubus allegheniensis*. ( $\times \frac{1}{2}$ )

best known. These belong to *Rubus allegheniensis* (Fig. 578). The plants in this group are tall and shrubby with purple canes armed with stout, straight prickles. The fruits are sub-cylindric or thimble-shaped, sweet, dull-colored, with many small closely packed drupelets, and are borne, as the name implies, in long clusters. The White blackberry, having amber-colored fruit and rounder lighter-colored canes, is an albino form of the Long-Cluster blackberry. Taylor and Ancient Briton are the most prominent representatives of the Long-Cluster group, while Iceberg best represents the albino form. (2) Var. *sativus* furnishes a number of varieties roughly grouped by horticulturists as the Short-Cluster blackberries (Fig. 579). These are characterized by smaller and weaker plants than the preceding, with green and nearly unarmed canes, short, leafless clusters, composed of globose glossy berries of few, large, juicy, irregularly set drupelets. The varieties most commonly grown are Agawam, Kittatinny, Lawton and Snyder. (3) The Leafy-Cluster blackberries belong to a species doubtfully known as *R. argutus*, Link, and are characterized by low bushy plants bearing short clusters with leaves intermingled with the flowers. Here belong the old Dorchester, one of the first varieties cultivated, and Early Harvest, a valuable commercial sort. (4) The Loose-Cluster blackberries are probably hybrids (Fig. 580) between the first group named and the dewberry (*R. procumbens*, Muhl.). The plants are low and spreading, with broad, jagged notched leaves, short clusters of large, roundish berries with juicy, glossy, loosely set drupelets. Early Wilson and Wilson Junior are the best known varieties of this group. (5) The Sand blackberry (*R. cuneifolius*, Pursh) is the parent of a few unimportant sorts, of which Topsy or the Tree blackberry is the best known. The plants of this group are low and shrubby, with stout recurved prickles; the clusters bear from one to four roundish berries of loosely set drupelets (Fig. 581).

XV. The American blackberry.—The Agawam; about natural size.

(6) The Evergreen blackberries, of unknown origin, to which the Himalaya is closely related, are commonly put in *R. laciniatus*, Willd., but may be but a cut-leaved form of the European bramble (*R. fruticosus*, Linn.). The vines are clinging, the foliage evergreen or nearly so, and the berries in the Pacific coast climate are large, black, sweet, and ripen through a period of two or three months. The Oregon Evergreen is the typical variety.

#### Propagation.

In nature the blackberry propagates itself from suckers and under cultivation young plants from suckers are thriftiest, but many varieties produce but few suckers and the natural process is a slow one with all kinds. A more expeditious method is to use root-cuttings. Such cuttings are usually made during the dormant season by taking up old plants and cutting the roots with pruning-shears into parts 2 inches long. The cuttings are then started under glass, or sown in furrows in well-prepared nursery beds in the spring. The cuttings should fall in sowing 2 inches apart in furrows 3 inches deep and should be covered with well-pulverized soil. The soil must be such that it does not bake as the young shoots appear. It sometimes requires two summers to produce plants ready for setting, but in the South, the Pacific coast, and under favorable circumstances in the East, yearling plants are strong enough for setting. Cuttings should be made from the roots of thrifty, healthy plants, preferably from a young plantation. It is contended and there are many facts to substantiate it, that propagating successive generations of blackberries from root-cuttings results in unproductive or even sterile plants.

Some blackberries from the several varietal groups may be grown in almost every condition of climate and soil in temperate regions, yet this fruit does best in a carefully selected environment. Blackberries cannot stand, without protection, more winter cold than the peach. In dry, hot climates the plants suffer and the berries are few, small, poorly colored and lacking in flavor. A deep, mellow, clay loam, well filled with humus, is most suitable for this fruit. Gravelly and sandy lands are usually too hot and dry. Flat wet lands are quite unsuited and in such soils the plants suffer alike from cold and heat; whatever else may be said of the soil, good drainage is imperative. A northern exposure is usually desirable. Fertilizers are little needed if the land be rich enough naturally to grow fair farm crops. Stable manure often induces rank-growing canes which produce but little fruit. Cover-crops of vetch or clover and some grain as oats or barley, sown in August, will supply much-needed humus and about all the plant-food usually necessary to add.

#### Field cultivation.

The plants are set in rows, 7, 8, or 9 feet apart, depending on the soil and the variety, and from 3 to 4 feet apart in the row. There should be room between

the rows for a two-horse harrow or cultivator to keep the plantation in good condition. Planting may be done by spade or in furrows 6 or 7 inches deep. A hoed-crop is usually grown between the rows the first year but seldom the second, as the plants need all the food and moisture to make sufficiently strong plants to bear a crop the third season. The canes are allowed to grow the first year to a height of 18 to 30 inches, when they should be cut back a few inches. The plants are thus pruned to cause them to grow low, stocky and upright, with many lateral branches, and so avoid the necessity of a trellis and yet be able to hold the crop up well. Trellising is troublesome and expensive.

Subsequent training and pruning consist in keeping the plants well branched, low and stocky, and in regulating the amount of bearing wood. Success in growing blackberries depends largely upon proper training and pruning. The fruit is borne upon one-year-old canes which should be removed as soon as the crop has been harvested. To allow them to stand through the growing season jeopardizes the proper development of the new canes, and often exposes them to infection from fungi. Five or six canes to the plant are quite enough; if there are more, the size and quality of the crop will be reduced. The canes should be headed-in annually during the growing season, as recommended for the first year. In the spring laterals are shortened-in, the amount of cutting-back depending upon how close the fruit is borne to the cane on the variety in hand. The laterals are usually left from 12 to 20 inches long. This spring pruning may be and often

579. The short-cluster garden blackberry. ( $\times \frac{1}{2}$ )

should be made a thinning process. Managed according to the directions just given, the plants need neither stakes nor trellises. In some plantations, however, a wire is stretched along each side of the row to hold the plants up, and in others, notably along the Hudson River, the plants are trained on two-wire trellises. In northern climates the training must be such as to provide for winter protection for many varieties.

Winter protection consists in laying down the canes and covering them wholly or in part with a thin mulch of straw or earth. The method of laying down must be varied with the variety, the soil and the amount of protection to be given. Three men can do the work most expeditiously; one goes ahead and digs the earth from the front and back of the roots, a second with fork or foot pushes the plant forward to the ground, the third puts on the mulch of earth or straw. Tender varieties are wholly covered, but the harder sorts need only a covering on the tips of the canes. The plants are raised in the spring just before or as the buds begin to

purst. Care must be taken not to break or split the canes. Such protection at present prices of labor will cost from eight to twelve dollars per acre. Winter injury is sometimes a matter of moisture as well as of temperature, and, in irrigated regions, late irrigation may obviate the necessity of a winter covering.

Thorough cultivation is essential for the proper conservation of moisture in a blackberry plantation, abundant moisture being a prime requisite for this fruit. It must be frequent and constant until the berries begin to turn in color. After the crop is harvested, the cultivator should be used to put the ground in shape for the cover-crop. The cultivator must be shallow-cutting since deep cultivation injures the roots, thereby weakening the plants, and inducing suckering. Mulching to take the place of cultivation is not to be recommended, except in small patches, and in the row with cultivation between rows.

Blackberries should not be harvested until fully ripe, and the sooner eaten after picking the better the quality. The fruits are not ripe when they attain full color but must be left on the bushes until soft, at which time they should part from the stem readily when the cluster is shaken. In picking, the berries should not be exposed to the sun. Well treated, the plants should bear some fruit the second season, and the third summer should give a fair crop. The length of time the plants will bear depends upon the variety, the soil and the treatment. When the stools become thin, the canes weak and the fruits small, the plantation should be cut down, this time coming usually when the bushes are ten or twelve years old.

Blackberry-growers have several troubles to contend with. Late frosts occasionally do much harm in northern latitudes. Borers often do much damage to canes and can be circumvented only by cutting out infested stalks. Two fungous diseases, orange rust and anthracnose, are dangerous, and are successfully kept in check only by cutting out the diseased wood. Root-galls are often found but it is doubtful whether they do much damage, and it is certainly not worth while trying to control them. Good treatment, especially as regards cultivation and pruning, with careful attention to destroy-

ing the pests mentioned as soon as practicable, will keep the plants in health.

The yields and profits in blackberry-growing are most encouraging to small-fruit-growers. In a plantation well cared for, a crop of two hundred bushels per acre may be expected. Blackberries are not suitable for long-distance shipments and monetary rewards come from local markets and here they are often large when climate, soil and general conditions are favorable. U. P. HEDRICK.

**BLACKBERRY LILY:**  
*Belamcanda.*

**BLACKWOOD:** *Acacia.*

**BLADDER-NUT:** *Staphylea.*

**BLADDERWORT:**  
*Utricularia.*

**BLAKEA** (Stephen

Blake, gardener, of the island of Antigua in the West Indies, who wrote "Compleat Gardener's Practice," London, 1664). *Valdesia*, Ruiz & Pav. *Melastomaceæ*. Rhothouse or greenhouse evergreen shrubs, of which two species are in cultivation for the showy flowers and prominent foliage.

Erect or scandent woody plants, sometimes small trees: lvs. opposite, leathery, mostly prominently 3-7-nerved, petioled, nearly or quite entire, often rusty-pubescent beneath: fls. rose-purple or white, showy and large, solitary or fasciated in the axils; calyx with 4 or more scales or bracts at base; petals 6, oblong or obovate; stamens 12 with thickened filaments, the anthers cohering and opening by 2 pores at the apex; ovary adhering to calyx, 4-6-celled: fr. a fleshy berry.—About 30 species in W. Indies and S. Amer. By some the genus *Amaraboya* (which see) is included with *Blakea*; *Amaraboya* has capsular rather than baccate fr.

*trinervia*, Linn. Shrub, in the wild the branches supporting themselves on neighboring bushes, and roots sometimes springing from the sts.: lvs. oval-oblong to elliptic, dark green above, often rusty-tomentose beneath, prominently 3-nerved: fls. pink or rose-color, solitary, on long stalks, in early summer. Mountain woods, Jamaica.—

A good plant for the warm conservatory.

*gracilis*, Hemsl. Compact shrub, 2-3 ft.: lvs. elliptic, acuminate, leathery, glabrous: fls. solitary, fragrant, 2 in. across, the petals white with a rose-colored spot at the base. Costa Rica.—Needs an intermediate temperature. L. H. B.

**BLANDFORDIA** (after George, Marquis of Blandford). *Liliaceæ*. Tender rhizomatous plants from Australia and Tasmania, placed by

581. Sand blackberry.  
( $\times \frac{1}{2}$ )

580. Wild, probable hybrid of blackberry and dewberry.

Baker (Jour. Linn. Soc. 11:364) between *Kniphofia* and *Funkia*; adapted to culture in greenhouses. *Blandfordia* of Andrews is a synonym of *Galax*.

Roots thickly fibrous: lvs. in two vertical ranks, narrowly linear, hard, persistent: fls. large,  $1\frac{1}{2}$ -3 in. long, showy, nodding, in short racemes, usually orange-red to crimson, with yellow tips.—The authorities recognize only 4 botanical species, but those below are horticulturally distinct from one another.

Being tenderer than the poker plant, and of more difficult culture, *blandfordias* are rarely grown in America. *B. flammea* var. *princeps* is the best kind. In New South Wales they grow in peat bogs and on shady mountain sides. During the growing season they must be shaded from bright sunshine, and during the resting season they may be placed in a light pit, in which they are not crowded or shaded by taller plants. They like a moist atmosphere and plenty of air, but not draughts. The chief element of the potting soil should be peat; if the peat is heavy, use freely; if light, use some loam, and pack firmly; if spongy, add some charcoal. Pot after flowering, in early spring, being careful not to overpot, and plan to leave roots undisturbed for two years at least. A top-dressing each year and liquid manure during growing season, is necessary to produce a good flowering. Perfectly hardy in central Florida when grown in lath-houses.—Propagation is by seeds sown in sandy peat with mild bottom heat, or usually by careful and not too frequent divisions of the root, made in early spring, after flowering, at the time of repotting, and preferably when strong offsets are formed.

A. *Margin of lvs. not roughish.*

**Cunninghamii**, Lindl. Lvs. 18-24 in. long, 3-4 lines wide, broader than in *B. flammea*: fls. 10-15, or even 20. Blue Mts. of Austral. B.M. 5734. Gn. 24:366.—This has been held to be synonymous with *B. grandiflora*, but it is horticulturally distinct, and the pedicels are shorter. Considered by Bentham the same as *B. grandiflora*.

AA. *Margin of lvs. roughish.*

B. *Fls. golden yellow, without any red.*

**aurea**, Hook. f. Lvs. 8-12 in. long,  $1\frac{1}{2}$ -2 lines wide: fls. 3-6, the only ones in the genus not touched with red; perianth wide-swelling, sometimes nearly as wide as long, more bell-shaped than any other species. New S. Wales. B.M. 5809.—By some considered a mere variety of *B. flammea*.

BB. *Fls. red-tubed and yellow-tipped.*

c. *Perianth long, 3-4 times as long as wide.*

**nobilis**, Smith. Lvs. 12-18 in. long,  $\frac{1}{2}$ - $\frac{3}{4}$  lines wide, dark green, sharply 3-angled: fls. 4-9, smallest of the genus, and narrowest. Near Port Jackson. B.M. 2003. B.R. 286. Var. **imperialis**, Hort. Fls. bright orange-red, margined with yellow or gold; larger than the type.

**flammea**, Lindl. Lvs. 12-18 in. long, 2-2 $\frac{1}{2}$  lines wide: fls. 4-12, typically constricted near the base of the tube and much lower down than in *B. Cunninghamii*. E. Austral. B.M. 4819. P.M. 16:353. F.S. 6:585; 18:1829 (as *B. Cunninghamii*). Var. **princeps**, Baker (*B. princeps*, W. G. Smith), has larger and brighter-colored fls. and is the best of the genus. The perianth is longer and less spreading than in the type, and swells very gradually from the base, instead of being constricted near the base. B.M. 6209. F.M. 1875:170. F.S. 22:2314. Gn. 47:324.

cc. *Tube short, scarcely twice as long as wide.*

**grandiflora**, R. Br. Lvs. 12-18 in. long, 3-4 $\frac{1}{2}$  lines wide: fls. 10-30. Distinguished from all others by having the filaments inserted instead of at the middle, but in var. **intermedia**, Baker, which connects *B. grandiflora* and *B. nobilis*, the filaments are inserted at the middle of the tube, the lvs. are narrower, and the fls. smaller.

Tasmania. B.R. 924.—The name *B. grandiflora* is now a misnomer, as the fls. are smaller than in any other species except *B. nobilis*.

*B. cordata*, Andr.—*Galax aphylla*.

WILHELM MILLER.

**BLANKET FLOWER**, *Gaillardia*.

N. TAYLOR.†

**BLAZING STAR**: *Liatris*; also *Mentzelia*.

**BLÉCHNUM** (Greek name for some fern), *Poly-podiaceæ*. Rather coarse greenhouse ferns, with pinatifid or pinnate lvs., and rows of almost continuous sori parallel to the midvein and close to it, covered with a membranous indusium. *Blechnum* is here recognized as including the species sometimes classified under the generic name *Lomaria* in addition to those species which all writers agree to put in *Blechnum*. The differences on which *Lomaria* has been based are very slight and are not recognized by leading European fern students. Besides, if the species included in *Lomaria* are kept separate, it is practically certain that they must be classified under the older name *Struthiopteris*.

In *Blechnum* occurs a singular knot in nomenclature. Linnaeus described two species in 1753, and to the West Indian one he gave the name *B. orientale*, citing figures, etc., showing that it is the plant that recent writers call *B. occidentale*. His East Indian plant he similarly called *B. occidentale*. The normal or ordinary usage has been followed below, the name *B. orientale* being given to the eastern plant.

*Blechnums* will thrive in almost any compost, but their leaves quickly turn brown and then black if watered overhead. Propagation of *Blechnum* is effected by spores.

*Blechnums* are very useful to florists for jardinières, and for specimen ferns. To attain best results, it is necessary to maintain an abundance of moisture at the roots, with a drier atmosphere than most other ferns require, to prevent leaves from turning brown during winter months. Average temp. 60° to 65° F. Soil, equal parts of rich loam and leaf-mold or peat. The spores of most *blechnums* germinate very freely if sown on a compost of loam and leaf-mold or peat in equal parts, and placed in a moderately moist and shady position in a temperature of 60° to 65° F. Some of the species send out creeping rhizomes, which develop young plants at the ends. When of sufficient size these may be detached and potted, and in a short time they will develop into good specimens. Some very attractive species are found among the hardy British *blechnums*. (N. N. Bruckner.)

INDEX.

A. *Fertile lvs. not strongly different from the sterile lvs.*

B. *Pinnæ strongly decurrent at the base, joining with the one next below.*

1. **brasiliense**, Desv. Fig. 582. Growing from a stout, slightly arborescent trunk 1 ft. or more long: lvs.

582. *Blechnum brasiliense*.

2-3 ft. long, 1 ft. or more wide, with the pinnæ set at an acute angle with the rachis, the lower much shorter and more distant. Brazil. S. 2:4.—Rather tender in Cent. Fla. and needs protection during winter.

2. *nítidum*, Presl. Habit of *B. brasiliense*, but much smaller: lvs. pinnate; pinnæ oblong-falcate, thickish, 2-4 in. long, serrate. Brazil.—Plants 1-2 ft. high.

3. *corcovadense*, Raddi. Pinnæ not cut to the rachis, much crowded and shorter than the last; longest pinnæ less than 6 in. long, attenuate at the tips; lvs. crimson when young, and gradually turning to a metallic hue before becoming permanently green. By some considered a variety of *B. brasiliense*. Brazil. Var. *crispum*, Hort., with wavy edges, may be commoner in cult. than the type.

BB. Pinnæ contracted at the base to the midrib, forming a very short stalk.

4. *occidentale*, Linn. Fig. 583. Lvs. from an erect rigid st., which is covered with brownish scales, 9-18 in. long, 4-6 in. wide, with the pinnæ truncate or even cordate at the base and slightly falcate. Mex. and W. Indies to Brazil.—A beautiful small fern.

5. *serrulatum*, Rich. Growing from an ascending nearly naked rootstock: lvs. 1-2 ft. long, 6-15 in. wide, with numerous narrow pinnæ, which are contracted at the base and of nearly uniform width throughout; margins finely serrulate; texture coriaceous. Fla. to Brazil.—Especially adapted for the edges of boggy ponds, river banks and the like. Soon forms dense clumps 2-3 ft. high.

AA. Fertile lvs. distinct from sterile lvs., very much narrower. (*Lomaria*.)

B. Plant with an erect rigid st.

C. Lvs. 6-12 in. long.

6. *Moorei*, C. Chr. (*Lomaria ciliata*, Moore). St. 6 in. high, 1½ in. thick: stipes blackish: lvs. 8-12 in. long, the upper pinnæ with a rounded auricle at the lower side of the base;

fertile lvs. narrow-linear. New Caledonia.

7. *lanceolatum*, Sturm. St. elongate, densely clothed with dark brown scales: lvs. 6-12 in. long, 2-4 in. wide, with close, slightly falcate pinnæ; texture leathery; fertile pinnæ linear spreading. Austral. and Polynesia.

CC. Lvs. 1½-3 ft. long.

D. Lower pinnæ connected at base.

8. *discolor*, Keys. St. ascending: stipes black, glossy, with dense scales at base: lvs. 1½-3 ft. long, 4-6 in. wide, with pinnæ narrowed suddenly toward the point; fertile pinnæ narrower and shorter. Austral. and New Zeal.

9. *gibbum*, Mett. St. 2-3 ft. high: stipes short, with black scales: lvs. 2-3 ft. long, 6 in. wide; fertile pinnæ narrower, 4-6 in. long. Var. *platyptera* is advertised. *L. intermedia*, Hort., may be derived from this species. New Caledonia.

DD. Lower pinnæ narrowed at base and distinct.

10. *tabulare*, Kuhn (*Lomaria Boryana*, Willd.). St. stout, erect 1-2 ft. high, woody, densely scaly: lvs. 1½-2 ft. long, 6-8 in. wide, narrowed and sometimes auricled at base; fertile pinnæ narrow-linear, close. W.

Indies to Patagonia, Mauritius and S. Afr.—Probably includes 2 or 3 species, among them *L. zamiaefolia*, Hort.

BB. Plant with a stout, short, creeping rhizome.

11. *spicant*, With. Sterile lvs. lanceolate, 6-9 in. long, 1-1½ in. wide, gradually narrowed below; fertile lvs. 1 ft. long, with longer stalks (6-9 in.) and narrowly linear pinnæ. Eu., W. N. Amer.—The large Californian form with lvs. 2-3 ft. long is possibly a distinct species. The European plant was early called *Struthiopteris spicant* by Scopoli, by which name it is now cited as the earliest generic name. Hardy; needs deepest shade. *Lomaria nipponica*, Kunze, Japan, usually larger than preceding, is much like it in other respects and probably is better to be considered as a form of *B. spicant* rather than as a distinct species.

*B. orientale*, Linn., is a large E. Indian and Polynesian fern with lvs. often 3 ft. long.—Well worthy of cult.

L. M. UNDERWOOD.

BLEEDING HEART: *Dicentra*.

R. C. BENEDICT.†

BLÉPHARIS (Greek, *eyelash*; referring to fringed bracts). *Acanthaceæ*. A large (80 species) genus of dwarf, often spiny shrubs and herbs, allied to *Acanthus*, and of similar culture. Fls. in bracted spikes; calyx cruciate, 4-parted nearly to the base, the 2 inner sepals much shorter than the outer; corolla short-tubed, the limb blue or white; caps. ellipsoid, flattened and woody.

*carduifolia*, T. Anders. (*Acanthus carduifolius*, Linn. *Acanthodium carduifolius*, Nees). Plant villous: lvs. lanceolate, sinuate-dentate, spiny: spike terminal, cylindrical: bracts roundish, palmately 5-spined at the apex. S. Afr.—Not commonly cult.

N. TAYLOR.†

BLEPHAROCALYX (*eye-lash* and *calyx*, probably referring to a fringed condition). *Myrtaceæ*. Woody plants, differing from *Myrtus* in having a thin crustaceous testa of the seed instead of a thick and horny one, and other minor characters, and by some authors united with that genus. There are about 30 species in S. Amer., but very little known in cult. B. *spiræoides*, Stapf (*Eugenia myriophylla*, Hort.), is a much-branched shrub, 9 ft. high, free-flowering: lvs. lance-linear, ¾ in. or less long: fls. small, pale yellow, in terminal panicles; petals 4. Brazil. B.M. 8123.

BLÉTIA (named for Louis Blet, a Spanish botanist). *Orchidaceæ*. Terrestrial orchids with globose or depressed pseudobulbs, from the apex of which arises a leafy st.; mostly hothouse plants.

Leaves plicate-veined: fls. borne on a lateral leafless st.; sepals and petals spreading, similar, or the latter broader; lip attached to the base of the column, 3-lobed, the lateral lobes erect, the middle lobe spreading, the disk with several entire or denticulate-crisped ridges; pollinia 8.—A genus of about 20 species in Trop. Amer.

A. Middle lobe of lip much crisped.

B. Petals as wide as sepals: fls. rose.

*verecúnda*, R. Br. Lvs. up to 3 ft. long, 2-4 in. wide: scape 2-4 ft. tall, the upper portion a raceme or panicle of numerous rose-colored fls. W. Indies and Fla. G.C. II. 26, p. 141. B.M. 3217 (as *B. acutipetala*).

BB. Petals broader than sepals, undulate: fls. deep purple.

*Shépherdii*, Hook. Lvs. up to 2 ft. long, 3-4 in. broad: scape, 2-3 ft. tall, the upper portion a raceme or panicle of numerous deep purple fls.; sepals oblong, acute, the petals broader, undulate; lip with the lamellæ white. Jamaica. B.M. 3319. P.M. 2:146.

AA. Middle lobe of lip not crisped.

*Sherrattiána*, Batem. Lvs. up to 4 ft. long, 3-4 in. broad: fls. bright rose, in a raceme of 10 or more; sepals oblong-lanceolate, obtuse; petals much broader,

rounded at apex; middle lobe of lip not crisped, deeply emarginate. Colombia. B.M. 5646.

*B. campanulata*, La Llave & Lex. Fls. bell-shaped, purple, with white center. Mex.—*B. hyacinthina*, R. Br.=*Bletilla*.—*B. patula*, Hook. Fls. up to 2 in. across, deep pink. Said to be a native of Haiti. B. M. 3518.—*B. Tankervillei*, R. Br.=*Phaius*.

GEORGE V. NASH.

**BLETILLA** (diminutive of *Bletia*). *Orchidaceæ*. Terrestrial orchids with pseudobulbs, and a leafy st. with a terminal infl.: sepals and petals nearly alike, somewhat spreading; lip 3-lobed, furnished with lamellæ, the lateral lobes surrounding the slender column; pollinia 8.—Outdoor orchids.

**hyacinthina**, Reichb. f. (*Bletia hyacinthina*, R. Br.). Pseudobulbs tuberiform: sts. up to 1 ft. tall, with 3-6 plaited lvs.: fls. racemose, on short pedicels; sepals and petals amethyst-purple; lip 3-lobed, amethyst-purple, the middle lobe nearly quadrate, denticulate. China and Japan. Gt. 15:527. Gn. 16:416. B.R. 33:60 (as *Bletia Gebina*). B.M. 1492 (as *Cymbidium*).—Grows beautifully in half-shady, moist places, soon forming large clumps. Prop. by division of the clumps.

GEORGE V. NASH.

**BLIGHIA** (W. Bligh, British mariner, who wrote on a journey in the South Seas, 1792). *Sapindaceæ*. Trees and shrubs with pinnately compound lvs. and axillary, racemose fls.; differs from *Cupania* in having a deeply cut calyx (rather than separate sepals) with the parts only slightly imbricate, and also in the fr.—One species in Guinea, now naturalized in the W. Indies, and yielding the akee, a 3-parted fr. with edible red aril that is much improved by cooking. The fls. are so fragrant as to deserve distilling. The tree reaches a height of 30 ft., and is cult. in Jamaica to an altitude of only 3,000 ft., but can endure slight frost. It is also cult. in S. Fla.

**sápida**, Kon. (*Cupania sápida*, Voigt.). **AKEE TREE**. Fig. 584. Lfts. 3 or 4 pairs, obovate-oblong, entire, veined; fls. pubescent, the oblong petals white and rather showy, bearing scales and stamens.

N. TAYLOR.†

**BLIGHT**. An indefinite term, popularly used to designate any sudden and inexplicable death of plants. The term is now restricted by botanists to parasitic diseases. These diseases are of two classes,—those due to bacteria or microbes, and those due to parasitic fungi. For an account of these troubles, see *Diseases*.

**BLITE**: *Chenopodium*.

**BLOODROOT**: *Sanguinaria*.

**BLOOMÈRIA** (named for Dr. H. G. Bloomer). *Liliaceæ*. Small summer-blooming bulbous plants of the allium kind.

A genus of 2 species, natives of S. Calif. In every way they are closely allied to *Brodiaea*, but differ in having the perianth parted nearly to the base. Bloomerias have a flattish corm, much like *Crocus*, covered with fiber, and not

often producing offsets. The lvs. are radical, slender, and grass-like: scape slender but stiff, 6-18 in. high, naked, except for short bracts beneath the many-rayed umbel; pedicels slender, jointed; fls. nearly rotate, less than an inch across, orange.

Bloomerias prefer a sandy, warm and well-drained soil. In northern California, with a minimum temperature of 15° above zero, they are perfectly hardy. In a colder climate, a covering of straw or leaves or a position in the coldframe would be a judicious precaution. Plant early, and see that the soil is light and sweet. They like the sun, and are good for forcing. The light soil and warmth of a pot more nearly approximates natural conditions than the open ground does in cooler climates. After ripening, it is best to dig and replant in fall. The seeds grow readily, and the plants flower in three to four years.

**aùrea**, Kellogg. Fig. 585. Scape roughish, 6-18 in.: lf. 1/4-1/2 in. broad: fls. numerous, bright orange, in a dense umbel; stamens nearly as long as the perianth,

585. *Bloomeria aurea*. (× 1/4)

the filaments dilated at the base. B.M. 5896 (as *Nothoscordum aureum*). G.C. III. 20:687.

**Clèvelandii**, Wats. More slender: lvs. 3-7: fls. smaller, keeled with brown, the stamens shorter. G.C. III. 20:687.—Less valuable than the other.

CARL PURDY.

**BLUEBELL**: *Campanula*.

**BLUEBERRY-CULTURE**. Fig. 586. Blueberries are fruit-bearing shrubs of the genus *Vaccinium*, long gathered wild in North America in great quantities and now about to be cultivated with success.

Success in blueberry-culture rests especially on the recognition of two peculiarities in the nutrition of these plants: first, their requirement of an acid soil; second, their possession of a root-fungus that appears to have the beneficial function of supplying them with nitrogen.

If blueberries are planted in a soil with an alkaline or neutral reaction, such as the ordinary rich garden or fertile field, it is useless to expect their successful growth. In such a situation they become feeble and finally die. Blueberries require an acid soil, and they thrive best in that particular type of acid soil which consists of a mixture of pure sand and peat. The peat may be of either the bog or the upland sort.

Good aëration of the soil is another essential. It is commonly but erroneously supposed that the swamp blueberry (*Vaccinium corymbosum*), the species chiefly desirable for cultivation, grows best in a permanently wet soil. It is to be observed, however, that the wild plants of the swamps occupy situations which though perhaps submerged in winter and spring are exposed during the root-forming period of summer and autumn, or, when growing in permanently submerged places, they build up a hummock or a cushion of moss which rises above the summer water-level and within which the feeding-roots of the bush are closely interlaced. In actual culture, moreover, it has been found that the swamp blueberry does not thrive in a permanently wet or soggy soil.

584. *Blighia sapida*. (× 1/6)

Although some species of *Vaccinium*, such as the common low-bush blueberry, *V. pennsylvanicum*, grow and fruit abundantly in sandy uplands that are subject to drought, the swamp blueberry grows best in soils naturally or artificially supplied with adequate moisture.

These then are the three fundamental requirements of successful blueberry culture: (1) An acid soil, especially one composed of peat and sand; (2) good drainage and thorough aëration of the surface soil; and (3) permanent but moderate soil-moisture. Under such conditions, the beneficial root-fungus which is believed to be essential to the nutrition of the plant need give the cultivator no concern, for it will propagate itself spontaneously and adequately, without any necessity of soil or plant inoculation.

#### Propagation.

Blueberry plantations may be formed by the transplanting of unselected wild bushes or by the growing of seedlings, but such a course is not the best. Seedling plants, even from the largest-berried parents, produce small berries oftener than large ones. Until nurserymen are prepared to furnish plants asexually propagated from superior stocks, the cultivator should begin by the transplanting of the best wild bushes, selected when in fruit for the size, color, flavor, and earliness of the berry, and the vigor and productiveness of the bush. These he should propagate by layering and by cuttings until his plantation is completed. By means of a combination of these two methods, a valuable old plant can be multiplied by several hundred at one propagation, the fruit of the progeny retaining all the characteristics of the parent.

Large berries cost less to pick than small ones and bring a higher price. A berry  $\frac{1}{2}$  of an inch in diameter has already been produced under cultivation and others of still larger size are to be expected.

While grafting and especially budding are useful in experimental work, neither method is suitable for commercial plantations because blueberry bushes are continually sending up new and undesirable shoots from the stock. The best season for budding is from the middle of July to the end of August. The budded plants should be protected from direct sunlight, and special care should be taken that the raffia wrapping does not become wet for the first three weeks.

The easiest way to propagate the swamp blueberry is by a special process of layering known as "stumping." In early spring, preferably before the buds have begun to push, all the stems of the plant, or as many as it is desired to sacrifice for propagation, are cut off close to the surface of the ground. The stumps are then covered to the depth of 2 inches with a mixture of about four parts of clean sand and one of sifted peat. The sand-bed must not be allowed to become dry, except at the very surface. The new growth from the stumps, which without the sand would consist of stems merely, is transformed in working its way through the sand into scaly, erect or nearly erect rootstocks which on reaching the surface continue their development into leafy shoots. Although roots are formed only sparingly on the covered bases of stems, they develop quickly and abundantly on these artificially produced rootstocks. By the end of autumn the shoots are well rooted at the base. They should remain in place in the sand-bed through the winter, exposed to freezing temperatures. Early in the following spring, before the buds have begun to push, each rooted shoot is carefully severed from the stump. The upper portion of the shoot is discarded, the cut being made at such a point as to leave on the basal portion about three buds above the former level of the sand-bed. The rooted shoots are potted in clean 3-inch porous pots in a soil consisting of two parts of rotted upland peat to one of sand and one of clean broken crocks. They are then plunged in

sand in a shaded coldframe or greenhouse, with abundant light but no direct sunlight. For the first two months the temperature should be kept below 65° F. When subjected to high temperatures, the newly cut shoots are liable to die and rot from the base upward. Watering should be infrequent, only sufficient to keep the soil moist but well aërated. The frame should receive ventilation but not enough to cause the new twigs to droop. They are very susceptible to over-ventilation and overheating just before they complete their primary growth. After the new twigs have stopped growing and their wood becomes hard, new root-growth takes place. Then secondary twig-growth follows. Not until this has occurred is the life of the plant assured. Those plants that make sufficient growth to require repotting during the first summer should be transferred to clean pots of 2 inches larger diameter in a standard blueberry soil mixture.

A very successful potting mixture, or nursery-bed mixture, for blueberry plants consists of one part of clean or washed sand, nine parts of rotted upland peat, either chopped or rubbed through a sieve, and three parts of clean broken crocks. No loam and especially no lime should be used. Manure is not necessary, and in the present state of our knowledge may be regarded as dangerous, although in small amounts it serves to stimulate the plants, at least temporarily. The danger from manure apparently lies in its tendency to produce an alkaline condition in the soil.

586. Swamp Blueberry. A cluster of berries on a budded greenhouse plant. ( $\times \frac{1}{2}$ ).

The use of crocks in the potting mixture is based on the fact that the rootlets seek them and form around them the same mats that they form at the wall of the pot, thus increasing the effective root-surface and the vigor of growth.

The peat most successfully used for potting blueberry plants is an upland peat procured in kalmia, or laurel, thickets. In a sandy soil in which the leaves of these bushes and of the oak trees with which they usually grow have accumulated and rotted for many years untouched by fire, a mass of rich leaf-peat is formed, interlaced by the superficial rootlets of the oak and laurel into tough mats or turfs, commonly 2 to 4 inches in thickness. These turfs, ripped from the soil and rotted from two to six months in a moist but well aërated stack, make an ideal blueberry peat. A good substitute is found in similar turfs formed in sandy oak woods having an underbrush of other ericaceous plants than laurel. Oak leaves raked, stacked, and rotted for about eighteen months without lime or manure are also good. The leaves of some trees, such as maples, rot so rapidly that within a year they may have passed from the acid condition necessary for the formation of good peat to the alkaline stage of decomposition, which is fatal to blueberry plants. Even oak leaves rotted for several years become alkaline if they are protected from the addition of new leaves bearing fresh charges of acidity.

By ordinary methods, cuttings of the swamp blueberry have been rooted only in occasional instances. Two successful methods, however, have been especially devised for these plants. The most novel of these but the one

easiest of operation is that of "tubering." This method involves the same principle as that employed in stumping, namely the forcing of new shoots in such a manner that their basal portions are morphologically scaly rootstocks, with a strong rooting tendency. This method of propagation from stem cuttings is called tubering because the treatment as well as the behavior of the cuttings is essentially identical with that which takes place in reproduction from tubers, as in the case of the potato.

The cuttings are made in late winter or early spring, and the whole plant may be used, including old stems an inch or more in diameter. With a saw and knife cut the wood in pieces about 4 inches long. Lay these horizontally in a shallow, well-drained box containing a bed of clean sand and cover them with half an inch of the same material. Water the sand well, cover the box with glass, and keep it at a temperature of 60° to 65°, or less if the equipment does not permit the maintenance of such a temperature. The sand-bed must be kept moist, although if there are only slight apertures beneath the glass, a second watering may not be required for several weeks.

At the temperature already specified, shoots should begin to appear above the sand within six weeks. The boxes should then be placed in good light but protected from direct sunlight, and, when warm weather approaches, they should be given the coolest situation available so as to keep the temperature below 65° as long as practicable. When the first shoots have stopped growing and their foliage has turned to a mature green color, they are ready to produce roots. A half-inch layer of finely sifted rotted peat should then be added to the surface of the sand-bed and thoroughly wet down with a fine spray. The box should remain in this condition, with a little ventilation but a saturated or nearly saturated atmosphere, until new shoots cease to appear. Meanwhile, during the spring and early summer the older shoots will have formed roots between the surface of the ground and the point at which they sprang from the cutting. After a shoot is well rooted it will make secondary twig-growth, and if the development of roots has not already been ascertained by direct examination, the making of such secondary growth is good evidence that rooting has actually taken place. If the rooted shoots have not already disconnected themselves from the dead cuttings they should be carefully severed with a sharp knife. They are then potted in 2-inch pots in the standard blueberry soil mixture already described, and during a period of three or four weeks they should be gradually changed from their saturated atmosphere and full shade to open air and half sunlight. If preferred, the shoots may remain in the original cutting-bed until the following spring, before potting, the cutting-bed being exposed to freezing temperatures during the winter.

When blueberry plants, either large or small, are grown in porous pots, the surface of the pot should never be allowed to become dry, for the rootlets, which grow through the soil to the wall of the pot for air, are exceedingly fine and easily killed by drying, to the great injury of the plant. This danger may be eliminated by plunging the pots to the rim in a well-drained bed of sand, or by setting the pot in another pot of 2 to 4 inches greater diameter, with a packing of moist sphagnum between, and crocks at the bottom.

A burning of the young leaves and growing tips of twigs is often produced by the hot sun from the middle of June to the middle of September. Plants in pots or nursery beds are easily protected from such injury and forced to their maximum growth by a half-shade covering of slats, the slats and the spaces between being of the same width. On cloudy days the shade should be removed. It should not be used in fall or spring.

During the winter the rooted cuttings or one-year-old plants should be kept outdoors, exposed to freezing temperatures, their soil mulched with leaves, preferably oak leaves. When kept in a warm greenhouse during the winter they make no growth before spring. Even then their growth is abnormal, often feeble, or sometimes deferred for a whole year.

Plants from cuttings or rooted shoots are ready for permanent field planting when they are two or three years old and about 1½ to 2 feet high. They are best set out in early spring before the buds have begun to push.

#### *The field plantation.*

It is a curious fact that these plants send out no new roots in spring until they are in full leaf, their flowering is nearly or quite finished, and their principal twig-growth has ceased. It is important, therefore, in taking up either a wild or a cultivated plant from the open ground, that as much as possible of the old root-mat be lifted with the plant, for upon this they depend for moisture until their new rootlets are formed.

In the case of mature wild bushes with very large root-systems, when it is practicable to secure but a fraction of the root-mat, say a disk only 3 or 4 feet in diameter, it is the best procedure to cut all the stems to the ground at the time of transplanting. The bush will then produce a new and symmetrical top of a size suited to the capacity of the roots. The wood that is removed may be used for cuttings if the plant is sufficiently valuable.

A plant pollinated with its own pollen, or with pollen from its asexual offspring, produces fewer, smaller, and later berries than a cross-pollinated plant. In a field of plants propagated from cuttings or layers, two parent stocks should be used, a row of plants from one stock being followed by a row from the other.

In the permanent field plantation the bushes should be set 8 feet apart each way. When they reach mature size they will nearly or quite cover the intervening spaces.

To secure full vigor of growth, the ground between the bushes must be kept free from all other vegetation. On rocky uplands a continuous mulch of oak leaves, when it is practicable to secure them, will help toward this end as well as keep the soil in the necessary acid condition. It is more economical, however, to choose such a location for the plantation as will permit the use of horse-drawn machinery, and will make mulching unnecessary.

The most favorable location for blueberry-culture is a boggy area with a peat covering and sand subsoil, the peat preferably of such a thickness that a deep plowing will turn up some of the underlying sand.

The land should be so ditched that the water-level can be kept at least a foot below the surface of the ground during the growing season or can be raised for subirrigation during a drought.

The ground should be plowed to the depth of about 8 inches and repeatedly harrowed during the season preceding the planting, in order to kill the vegetation. After the plants are old enough to have formed a root-mat, the harrowing should be very shallow, not more than 2 or 3 inches, so that the roots will not be injured.

By proper manipulation in the greenhouse, seedling blueberry plants can often be made to ripen a few berries in less than a year, but they do not come into commercial bearing in field plantations until they are about five years old, when the plants are 3 to 4 feet high. They then increase slowly to full size and full bearing.

The field plantings resulting from the recent experiments in blueberry culture are too young to show the mature yield. Fortunately, however, there has been found, near Elkhart, Indiana, a small blueberry plant-

ing of mature age, believed to be the only commercial plantation in existence, which sets forward our knowledge of yields by at least a decade. The plantation is a little less than two and a half acres in extent. It was started in 1889 in a natural blueberry bog, which was first drained and then set with unselected wild blueberry bushes. Exact records of yield and receipts are available only for the years 1910 to 1912. They are as follows:

Year	Yield Qts.	Price (approx. avg. per qt.)	Receipts
1910 (a year of "almost total failure" because of late spring freezes) . . . . .	1040	17 1/8 cts.	\$178 25
1911 . . . . .	5620	12 7/8 cts.	725 25
1912 . . . . .	5900	12 7/8 cts.	758 25

The annual expenses for weeding, cultivation, and irrigation were about \$50. The cost of picking was 5 cents a quart. The general cost of maintenance of the equipment was about \$5 per year, the crates and boxes being used repeatedly.

Estimating an annual charge of \$30 for interest, \$5 for taxes, and \$10 for depreciation, the profits for these three years are computed as follows:

Year	Profits per acre
1910 . . . . .	\$10
1911 . . . . .	139
1912 . . . . .	147

It must be borne in mind that these figures are based on the yields from wild bushes transplanted without selection as to individual productiveness or the size of the berries. With bushes propagated from selected stocks, the yield should be greater and the berries much larger, this greater size probably effecting a reduction in the cost of picking and certainly an increase in the selling price.

FREDERICK V. COVILLE.

BLUE FLAG: *Iris*.

BLUETS: *Houstonia*.

**BLUMENBÁCHIA** (after Dr. J. F. Blumenbach, professor at Göttingen, 1752-1840). *Loasacæ*. S. American plants allied to *Loasa* and *Mentzelia* (prairie lilies), not cult. in Amer. because of their covering of stinging hairs. The fls. are odd and pretty, axillary, solitary and bracteate: lvs. opposite, lobed. The garden forms are mostly treated as tender annuals. Prop. by seeds, to be sown in pots in spring. Transplant only when danger from frost is over.

*B. chuquitensis*, Hook. f. Lvs. 8-10 in. long: fls. 1 1/2-2 in. long, brick-red, tipped yellow without, and yellow within; petals 5-10, boat-shaped. Peru, Ecuador. F.S. 22:2358. B.M. 6143.—*B. coronata*, Haage & Schmidt. 1 1/2 ft.: lvs. narrow, bi-pinnatifid: fls. half hidden by the lvs., 2 in. diam., pure white. R.H. 1874, p. 58. F.M. 1874. 139.—*B. grandiflora*, Don (B. contorta, Hook. f. B.M. 6134). Lvs. 4-6 in. long: fls. 1 1/2-2 in. long, wholly red; scales 1/2 in. long, cup-shaped, green; stamens in 5 bundles, with long filaments. Peru. *B. insignis*, Schrad. St. climbing, 4-sided: petals white, unguiculate. B.M. 2865.—*B. intertia*, Brit. (Cajophora lateria, Benth.) Lvs. pinnate, with roundish lobed lflets: fl-stalks, twin, single-fld.: fls. orange-red. S. Amer. B.M. 3632. B.R. 24.22.

N. TAYLOR.†

**BOCCÒNIA** (after Dr. Paolo Bocconi, Sicilian botanist and author). *Papaveracæ*. PLUME POPPY. TREE CELANDINE. Tall garden herbs, suitable to the hardy border.

Herbs, but sometimes almost shrubby, glaucous: lvs. lobed: fls. small, many, in terminal panicles; sepals 2, colored; petals wanting; stamens many: fr. a stalked caps., few-seeded.—Four or 5 species in American tropics, and China and Japan. The well-known China-Japanese species, *B. cordata*, is by some recent authors referred to *Macleya*, *B. frutescens* and *B. integrifolia*

(latter apparently not cult.) representing *Bocconia* as limited.

The large, handsome leaves remind one, by their texture and lobing, of bloodroot and *Stylophorum*, which belong to allied genera. The flowers are very unlike our common poppies, being small and without petals, but they are borne in great feathery or plummy masses, in terminal panicles raised high above the heavy foliage, making the plant unique in its picturesque general appearance. Hence, it is much used for isolated lawn specimens, or for very bold and striking effects, being especially adapted to be viewed at long distances. It is also placed in shrubberies, wild gardens, and at the back of wide borders. It spreads rapidly by suckers, any of which, if detached, will make a strong plant in a single season. The plume poppy seems to be much hardier in America than in the Old World. It was popular early in the century, but was neglected,

587. *Bocconia cordata*.

probably because it spread so rapidly. Lately it has become popular again. It deserves to be permanently naturalized in the American landscape. To produce the largest specimens, it is well to plant in very rich soil, give the old clumps liquid manure in spring, and cut off the suckers. Propagation chiefly by suckers. See *Pflanzenreich*, hft. 40, p. 217 for the latest monograph.

*cordata*, Willd. (*B. japonica*, Hort.). Fig. 587. Hardy herbaceous perennial: height 5-8 ft.: lvs. large, glaucous, heart-shaped, much lobed, deeply veined: fls. pinkish; stamens about 30. China, Japan. B.M. 1905. Gn. 54, p. 279. Gng. 5:342.

*microcarpa*, Maxim. Perennial, 9 ft.: fls. golden brown or bronzy, in immense panicles, summer: lvs. much as in *B. cordata*. N. China. R.H. 1898, p. 362, f. 125.

*frutescens*, Linn. Perennial, somewhat shrubby, 4-9 ft.: lvs. pinnatifid, pale green, often glaucous beneath, ovate-oblong, cuneate at the base, 6-12 in. long: fls. greenish, the panicle often a foot long. Oct. Mex. and Peru. L.B.C.: 83.—Intro. by Franceschi in 1895.

*B. integrifolia*, Humb. & Bonpl. 9 ft.: fls. greenish: lvs. nearly entire. Peru. Is sometimes cult.—*B. macrocarpa*, *B. Giráldea* and *B. Thunbergii* are trade names, the first two referable to *B. cordata*, the last probably to *B. microcarpa*.

N. TAYLOR.†

**BOËA** (name obscure, probably personal). Sometimes spelled *Boëa*. *Gesneriaceæ*. Allied to *Streptocarpus*, sometimes found in choice collections. Differs from *Streptocarpus* in having a short corolla-tube and a broadly campanulate fl., no disk, and very minor characters. Boeas are perennial herbs with ovate or oblique lvs. radical or opposite on a very short st.: peduncles axillary or elongated leafless scapes, the fls. small or medium in size, blue.—Species 16–20 in E. Asia and to Austral. and Seychelles. **B. Clarkeana**, Hemsl., from China, has been offered in the trade: lvs. radical, roundish, strongly crenate, petioled, bronze-green above and maroon-red beneath: fls. 3–4 on each peduncle, clear azure-blue with a whitish spot.

**BOEHMERIA** (G. R. Boehmer, a German botanist). *Urticaceæ*. A fiber plant; and a greenhouse shrub or tree.

Leaves alternate or opposite, often 3-nerved: fls. monœcious or dioecious, in dense clusters; petals none; sepals 2–5: fr. a flattened achene. *B. nivea*, Gaud., of Trop. Asia, is cult. in some countries as a fiber plant, and has been intro. into this country for that purpose. Now grown extensively in Calif. and La. for its fiber. See Report No. 2, office of Fiber Investigations, U. S. Dept. Agric., and *Cyclo. Amer. Agric.* II, p. 284. It produces ramie. It is a strong-growing, large-lvd. perennial, well suited to the border as an ornamental subject. A genus of 45 widely distributed species of shrubs, trees or herbs.

**argentea**, Lind. Fig. 588. Tree, 10–30 ft.: lvs. alternate, ovate, long-acuminate, 8–10 in. long, 3–5 in. wide, usually silvery: fls. in an axillary compound catkin-like cluster, 6–10 in. long. Mex.—An excellent warmhouse plant, cult. mostly in botanic gardens, but worthy of wide attention.

*B. macrophylla*, Don. A shrub or small tree: lvs. lanceolate, 6–9 in. long, serrate, prominently 3-nerved: spikes slender, usually shorter than the lvs. Himalayan region. N. TAYLOR.

**BOG-GARDENING.** The growing of plants in swamps, marsh-spots and bogs: distinguished from water-gardening or aquatic-gardening in the fact that the plants are not immersed or floating but grow mostly free above the soil. When water-gardening is made to include bog-gardening, confusion in practice is likely to result because the cultural requirements are unlike.

Bog-gardens may be separate areas in themselves, or they may comprise the edges of water-gardens or the spongy ground along runnels or the margins of pools. Bog-gardening is mostly a practice in colonizing plants, finding the ones that are specially adapted to the particular place. The artistic scheme is one of informality. If the place is very soft, stepping-stones may comprise the walks. Hereabouts may be grown the many marsh and wet-land plants, many of which are showy and also little known to cultivators. The sparganiums, pontederias, some of the hibiscus (page 338), many orchids, loosestrifes, cephalanthus, utricularias, and a host of others will occur to frequenters of morasses and distant shores. L. H. B.

**BOLÁNDRA** (H. N. Bolander, Californian botanist). *Saxifragaceæ*. Two species of small W. American herbs offered for borders and wild gardens.

Flowers purplish in lax corymbs; petals 5, inserted on the throat of the 5-lobed calyx; stamens 5, alternate with petals. Delicate herbs, suitable for rockwork where there is a plentiful supply of moisture.

**oregana**, Wats. A foot or 2 high, pubescent and glandular: lvs. laciniately toothed and lobed: fls. deep purple; tube of the calyx equaling the teeth and a little shorter than the petals: pedicels reflexed in front. Ore. and Wash.—Intro. by Gillett in 1881.

The first-described species, *B. californica*, Gray, seems not to have been offered in the trade. It is a smaller species, less pubescent

with smaller fls., the lower lvs. round-reniform and 5-lobed: plant 3–12 in. high, the sts. weak and slender.

**BOLDÔA FRAGRANS**, cult. in S. Calif.: *Peumus*.

**BOLËTUS**: *Mushroom*.

**BOLLEA** (in honor of Dr. Karl Bolle). *Orchidaceæ*. Epiphytic greenhouse orchids without pseudobulbs, with flat lvs., and lateral 1-fl. peduncles: sepals and petals nearly alike, spreading, the lateral sepals forming a distinct chin; lip articulated to the column-foot, entire, the margin revolute, furnished with a thick ridged plate, over which the stout column extends; pollinia 4.—A Trop. American genus of 4 species.

*A. Recurved tip of lip purple.*

**violaceum**, Reichb. f. (*Hüntleya violacea*, Lindl. *Zygopetalum violaceum*, Reichb. f.). Fls. deep violet; sepals and petals broad, undulate; lip ovate, cordate, the tip recurved. British Guiana. F.S. 7:678. P.M. 8:1.

588. *Boehmeria argentea*.  
( $\times \frac{1}{2}$ )

*AA. Recurved tip of lip yellow.*

*B. Fls. violet or purple.*

**cælestis**, Reichb. f. (*Zygopetalum cæleste*, Reichb. f.). Lvs. up to 1 ft. long and 2 in. broad: fls. 3–4 in. across; sepals and petals bluish violet, with yellow tips, the dorsal broadly obovate; petals similar to the dorsal sepal; lip colored like the petals, the crest buff. Colombia. B.M. 6458. Gt. 31:1075. Lind. 2:61. G. 16:99. Gn. 31, p. 121.

*BB. Fls. rose-colored.*

*c. Sepals and petals light rose.*

**Pátinii**, Reichb. f. (*Zygopetalum Pátinii*, Reichb. f.). Lvs. up to 1 ft. long and 2–3 in. wide: fls. 3–4 in. across; sepals and petals light rose, undulate, the lower side of the lateral sepals darker; lip triangular-hastate, yellow. F.M. 1875:147. G.C. II. 3:9.

*cc. Sepals and petals dull rose, tipped with yellow and margined white or yellow.*

**Lalindei**, Reichb. f. (*Zygopetalum Lalindei*, Reichb. f.). Lvs. as in *B. Pátinii*, but fls. smaller and darker; lip ovate-hastate, yellow. Colombia. B.M. 6331. O.R. 8:369.

GEORGE V. NASH.

**BOLLEO-CHONDRORHYNCHA.** A cross of *Bollea cælestis* with probably *Chondrorhyncha Chestertonii*, with both of which it was found growing in Colombia, whence it was intro. to the collection of Otto Froebel of

Zurich in 1898. It has received the name *B.-C. Froebeliana*, Cogn. This natural hybrid has a slender erect peduncle 4 in. long, at the top bearing 2 membranous bracts half the length of the ovary: fl.  $3\frac{1}{4}$  in. wide, the sepals and petals lanceolate-ligulate, yellow-white, lightly tinged with rose, especially at the summit; dorsal sepal pointed, curving outward at the top, the lateral ones much incurved; petals obtuse, almost flat, curved

589. *Boltonia latiquama* ( $\times \frac{1}{2}$ )

back at the tip; lip somewhat thick and fleshy, more delicate than in *B. cernitoides*, the blade widely obovate and rounded; crest orange-yellow, with a yellowish border and an edge of brown-purple.

**BOLOCANTHUS, BOLUSANTHUS:** *Lophocarpus*.

**BOLTÔNIA** (James Bolton, English botanist). *Compositæ*. FALSE CHAMOMILE. Four or 5 species of aster-like glabrous often glaucous herbs of the United States and eastern Asia, sometimes planted in borders and wild gardens.

They are tall and leafy plants, blooming profusely in late summer and autumn, and excellent for the hardy border. They have alternate, entire and sessile or clasping lvs. and angled, often striate, sts. Differs from Aster in having very few pappus bristles which in Aster are numerous, and in other technical characters.

Boltonias are of easiest culture. They take care of themselves when once established. Propagation is effected by division. Should be better known to gardeners. They stand without staking.

**asteroides**, L'Her. (*B. glastifolia*, L'Her.). Sts. 2-8 ft., simple below and branching at the top; lvs. broadly lanceolate or the upper narrower: heads short-peduncled, numerous, the rays varying from white to violet and purple; involucre bracts lanceolate and acute, greenish; scales of the pappus numerous and conspicuous, the 2 awns sometimes missing. Pa. to Ill. and S.

B.M. 2381, 2554. Mn. 1:33. Gn. 74, p. 438. R.H. 1903, p. 59.—Perennial.

**latiquama**, Gray. Fig. 589. A handsomer plant, with larger and more showy heads with blue-violet rays: involucre bracts oblong or obovate and obtuse (often bearing a minute point); pappus scales small, the awns present and conspicuous. Kan. and Mo. to Ark. G.F. 5:271 (adapted in Fig. 589). C.L.A. 7:490. Perennial. Var. *nana*, Hort. A dwarf form scarcely 2-3 ft. tall, with pinkish rayed fls. Branches freely from the base.

*B. cantoniensis*, Franch. & Sav., is native to Japan, where the young plants are used for greens. See Georgeson, A.G. 13, p. 8, fig. 4. It is annual. Has not yet appeared in the American trade. Gray restricts *Boltonia* to the U. S., and regards his species as of another genus. *B. laevigata*, Hort. = *B. asteroides* (?).

L. H. B.  
N. TAYLOR.†

**BOLUSANTHUS:** *Lonchocarpus*.

**BOMAREA** (named after the French botanist, J. C. W. de Bomare). *Amaryllidaceæ*. Tender South American plants allied to *Alstrœmeria*, and with similar fls. but a twining habit. Lvs. parallel-veined, usually borne on short, twisted petioles: fls. in pendulous umbels, variously colored and spotted, borne in early spring and summer; perianth funnel-shaped; tube none.

The most beautiful species now grown is probably *B. Carderi*. It has large terminal cymes of rose-colored flowers, about 2 inches long, with dark purple spots and blotches. Another valuable form is *B. Shurtleworthii* with pale yellow flowers, spotted with green.

Bomareas delight in a rich, fibrous soil, and require plenty of water during the growing season, which begins early in the spring. A little well-decayed cow-manure mixed with the soil improves the growth and results in larger clusters of flowers, as does also manure watering during the growing season. Late in fall the stems are cut down to the ground and the roots are kept in the soil in a dry state. While they often make satisfactory pot-plants, they do best when planted out in an open sunny position in a cool conservatory where they have plenty of air in summer. In the south, bomareas may be grown in the open air on trellises in half-shady places. All are woodland plants and cannot be successfully grown in the glaring heat of the sun.

Propagation is by fresh seeds, which germinate readily if sown in shallow pans in a warm propagating-house; also, and more rapidly, by careful division of the rhizome, to which some of the roots should be attached.

590. *Bomarea Salsilla*.  
( $\times \frac{1}{4}$ )

A. *Perianth-segms. equal.*

B. *Umbel simple; fls. medium-sized.*

**oligantha**, Baker. Lvs. 3-4 in. long, oblong, acute, lax, thin, densely pubescent beneath: fls. 6-8 in an umbel; bracts large, lf.-like; segms.  $1\frac{1}{4}$  in. long, outer dull red, inner bright yellow with reddish brown spots. Peruvian Andes.

## BB. Umbel compound.

## c Fls. small.

**Salsilla**, Herb. (*B. oculata*, M. J. Roem. *Alstræmeria oculata*, Lodd.). Fig. 590. Lvs. 2-4 in. long,  $\frac{1}{2}$  in. broad, lanceolate or oblong-lanceolate, moderately firm, glabrous beneath: umbel 4-15-rayed; rays 1-3 in.

long, 1-3-fld.; bracts small; fls. pink or red, marked with blue and dark purple within. Chile. L. B. C. 19: 1851. B.M. 3344.

## cc. Fls. large.

## Cárderi, Mast.

Lvs. 4-6 in. long,  $1\frac{1}{2}$ -3 in. broad, oblong, acute: umbel 1 ft. long, 6-9-rayed; rays 1-4-fld.; bracts large, leafy; perianth-segms. 2 in. long, outer pale pink, spotted brown near the top, inner greenish white, much spotted. F. M. 1876: 239. G.C. II. 5:793.

## chontalénsis, Seem. Lvs. 6-8 in.

long, broadly lanceolate: umbel very large; rays 4-6-fld.; fls. numerous,  $2\frac{1}{2}$  in. long; outer segms. waxy, wavy margined, rosy red or pink with brown spots, inner ones thinner, pale greenish yellow, spotted.—The largest-fld. species; very effective when well grown.

**Shuttleworthii**, Mast. Lvs. 5-6 in. long, oblong, acute, glabrous: umbel 1 ft. long, 5-10-rayed; rays usually 3-fld.; perianth-segms. 2 in. long, outer reddish, inner greenish yellow. Colombian Andes. G.C. II. 17:77, 85.—The curious egg-shaped tubers terminate unbranched roots, which spring from a rhizome about 1 in. wide. Having no eyes or buds, they cannot be used for propagating.

## AA. Perianth-segms. not equal, the inner longer.

## B. Umbel simple.

**patacocénsis**, Herb. (*B. conferta*, Benth.). Sts. purple-tinted, pubescent: lvs. 5-6 in. long, oblong-lanceolate, pubescent beneath: fls. 20-30; outer segms.  $1\frac{1}{2}$  in. long, bright red; inner ones  $2\frac{1}{2}$  in. long, bright red, yellow-keeled, with a few spots. Andes of Ecuador and Colombia. G.C. II. 17:187. B.M. 6692.—When well grown, the umbel is very dense and many-fld.

**Caldasiána**, Herb. Lvs. thin, spreading, oblong, acute, distinctly petioled, 3-6 in. long, glaucous, puberulent beneath: umbel 6-30-fld.; bracts many, oblong-lanceolate; pedicels 1-2 in. long, pilose; outer segms. reddish brown, about 1 in. long, inner  $\frac{1}{2}$  in. longer, bright yellow. B.M. 5442 (as *Alstrænesia Caldasi*).

## BB. Umbel compound.

**vitellina**, Mast. Lvs. 3-4 in. long, ovate-oblong: umbel about 12-rayed; perianth-segms. bright yellow, outer  $1\frac{1}{2}$  in. long, inner 2 in. long; bracts large, leafy. Peruvian Andes. G.C. II. 17:151.

*B. Wrecklei*, Lemoine. Lvs. lanceolate, acuminate, bright green: fls. about 12 in a terminal umbel, vermilion—orange with orange-yellow inside. Costa Rica.

N. J. ROSE.†

**BÓMBAX** (a Greek name for *raw silk*, alluding to the cottony contents of the pods). *Bombacææ*. SILK COTTON TREE. A genus of 50 species of tropical shrubs and trees, with digitate 5-9-foliolate lvs., 1-fld. axillary

or clustered peduncles, and usually large white or scarlet fls. Specimens are rarely seen in cult. in fine glasshouses, and only 1 of the species appears to be in the American trade. The bark of some species produces commercial fiber such as the Kapok fiber.

**malabàricum**, DC. (*B. Ceiba*, Burme.). Fig. 591. Large deciduous tree, the branches in whorls, the trunk

591. *Bombax malabaricum*. ( $\times \frac{1}{6}$ )

592. Borage—*Borago officinalis*. ( $\times \frac{1}{3}$ )

and branches spiny: lvs. 5-7-foliolate, palmate, the lfts. entire, cuspidate: fls. 6-7 in. long, clustered near the ends of the branches, red or scarlet, sometimes white. fr. a 5-valved caps., silky. India.—A very showy plant, excellent for warmhouse, but tender. Intro. in U. S. by Royal Palm Nurseries in 1912. N. TAYLOR.

**BONESET**: *Eupatorium perfoliatum*.

**BOOKS**: Literature.

**BORAGE** (*Borago officinalis*, Linn.). Fig. 592. *Boraginææ*. A coarse annual plant grown for culinary use in some parts of Eu., as in Germany. Used as a pot-herb and sometimes with salads. Only the young lvs. are palatable. Mostly known in this country as a bee-plant and for its handsome blue or purplish racemed fls. It is a hairy plant,  $1\frac{1}{2}$ -2 ft. high, with oval or oblong lvs. Eu., N. Afr. Eng. Bot. 1:36. *Borago laxiflora* DC., is a small, decumbent alpine, but of easy cult., offered in the trade. It has alternate, ovate lvs., hairy throughout, and pretty, long-peduncled, purple or violet fls. Corsica. B.M. 1798.—Little known in Amer. N. TAYLOR.†

**BORASSUS** (an old name, of no significance here). *Palmææ*, tribe *Borassinæ*. Tall unarmed palms, with ringed trunks.

Leaves large, palmately flabelliform; plicate sheath short; petiole spiny; ligule short rigid: fls. small, densely packed in pits on the catkin-like branches of a spathe which comes out between the lvs.; stamens 6: fr. large, subglobose, brown.—Species 1. Trop. Afr. For cult., see *Latania*. The seeds are

593. *Borassus flabellifer*.

very hard and do not germinate readily unless given strong bottom heat and abundant moisture.

**flabellifer**, Linn. (*B. flabelliformis*, Murr. *B. æthiopicum*, Mart.). MEELALLA, a native name for young plants; called also PALMYRA PALM by the Hindoos. Fig. 593. St. 60–70 ft. high; lvs. 8–10 ft. long, broader than long; lf-segms. bifid at the apex, lanceolate or sword-shaped in outline.—Widely cult. One of the most useful palms of India. The frs. are very large. Many parts of the plant are utilized by the natives as food and in the arts. Wood black, very hard. This plant requires rich soil and strong heat for its best development, and is rather slow-growing under cult., especially while young.

N. TAYLOR.†

**BORDER.** In gardening practice, the term "border" is employed to designate definite strip-planting on the margins. The margin may be along the boundary of a yard, park or other area; close about a residence or other building; or a parallel of walks and drives. In all these positions, the border becomes a part of the artistic landscape plan. In some cases borders are designed separately as flower-garden or ornamental features, as margins or boundaries of an avenue of sold

### The hardy border.

The hardy border has assumed a new relation to ornamental planting within recent years in America. Once only occasional, it now forms a dominant part of many gardens previously given up almost entirely to the display of greenhouse plants or tender annuals. Properly designed for a specific purpose, it is capable of giving a maximum of pleasure for a minimum of effort and expense. Now that plants, especially American native plants, are coming to be valued for their intrinsic beauty and interest rather than for their rarity and cost, the hardy border is a more personal and individual expression than some other forms of garden effort.

The informal hardy border is often the most charming, and nature has provided us with many roadside or meadow-corner examples of exquisite beauty. Such a border may change not only with the day but almost from morning until afternoon during the luxuriant June weeks. It may follow the chromatic balance of the season from the brightness of spring hues through the cooler tones of summer until the rich tints of the autumn asters and goldenrods blend into the warmer colors of the aftermath that remains to enhance the effectiveness of the winter's snow in making the border a continuous pleasure. This informal planting can be handled with individuality and changed to suit knowledge, circumstance and surroundings without destroying its charm. The wild things that are picked up—let us hope without ever exterminating a plant colony anywhere—in a day's woodland ramble, belong in this informal border. Often the border is built around or with reference to some essential tree or larger shrub, as a rugged old pine, or a picturesque clump of lilac, or a mass of rhododendrons. It may combine shrubby, herbaceous and bulbous plants to advantage.

The formal hardy border has been exemplified in some notable New England gardens. It is usually formed with masses of similar plants—as a long strip of delphiniums, a great body of aquilegias, serried rows of phloxes, or lupines,—and at times is effectively combined with architectural adjuncts in the so-called "Italian" style, or with evergreen trees of formal or clipped outline. But the "barbered" formal border is passing, and even in the best American example of a formal hardy garden, made up of various borders, the edging of the daintily informal evergreen *pachysandra* gives a note of variation that is significant and pleasing. The hollyhocks, foxgloves and similar treasures of all gardens are indispensable in the formal border to carry line and give contour and mass. In one notable example, the background of a succession of fine hardy borders is a clambering mass of Crimson Rambler roses hanging over a great wall.

In the conventional hardy border, the shrubby plants are used less freely than the herbaceous perennials, and the bulbs still less freely, as yet. The shrubs, if selected properly as to character, eventual height, color, time of bloom and effect of foliage, may well form a framework in which to set the higher colors of the composition supplied by the herbaceous plants—the peonies, iris, gaillardias, veronicas, and the like. Or it is practicable to build the border entirely without shrubs, depending only on the masses and forms available in the plants that die to the ground each winter. With the increase in variety of herbaceous plants now commercially available everywhere, a very delightful and continuous succession of bloom may be had.

The bulbous plants—of course as fully herbaceous as any, but distinguished in trade parlance by their "onions" instead of roots, and their different dormant conditions—should come to more importance in the hardy border. They give colors, forms, fragrance and effects unique to the class. The popular conception of "bulbs" has centered around tulips and hyacinths, the so-called "Dutch" bulbs, but the various narcissi, the

594. Border planting about a residence.

or of a formal walk. The border derives its value from its relationship as well as from its intrinsic character. It is a conception of boundaries and inclosures, and consequently is part in a design of open centers and good lawns. It develops mass effects rather than the detached and spot effects of lawn beds and of single planting; and it derives much of its pleasing result from its length, distance and perspective. The border may be permanent, comprised of hardy plants; or it may be a bedding form of gardening, using temporary subjects; or it may have a framework of hardy material, with inter-planting of bulbs and annuals and greenhouse plants. Borders are often designed to carry and emphasize one idea,—the idea of larkspurs or of hollyhocks, for example; and in such cases the dominance is secured by similarity, and repetition of one plant-form. These borders, when well made, are most effective; but they do not cover the entire season unless expensive efforts are made to replant with other things as soon as the desired effects are passed. Figs. 594–596 show the placing of borders in recognized landscape plans; and Fig. 597 suggests how a mixed hardy border works itself out. Fig. 598 shows the emphasis of a single strong plant-form set against a border rather than to be placed alone in the lawn without background or support.

L. H. B.

XVI. Botanic garden.—The formal garden of Johns Hopkins University

scillas, snowdrops, anemones, and especially the lilies, are more adapted to the permanent border than these. The narcissus, for instance, in several largely grown forms, adapts itself to both the informal and formal border plantings. Combined with iris and lilies, and using certain of the late-flowering tulips, effects as permanent as they are pleasing are now produced, and at little expense. The fancier of rare things may indulge

595. Border inclosure of a city square.

himself according to his resources with the newer and more unusual forms; there are narcissi in commerce at \$60 each and \$5 is cheerfully paid for a gladiolus bulb.

While the nature of hardy garden flowers, with the relief of varied green foliage, seems to make agreeable a heterogeneous color-combination, yet more pleasing pictures are painted in harmonizing or properly contrasting hues. The raw scarlet of the oriental poppy or the kniphofia, for example, does not "go" or compose agreeably with pink or magenta phlox. It is well to keep tiger lilies and certain pink hibiscus colors from fighting each other, as another example. Indeed, a fascination of the hardy border is this opportunity to select and combine hues that shall match and succeed each other agreeably. A border is in mind that blended insensibly from deep crimson at one end through white to pink and white to yellow along to orange and scarlet at the other end. There was no clash. It must be said, however, that if the larger and more vividly colored flowers are judiciously placed, the general mixture of blooming plants in a border is wholly agreeable, even as an oriental rug including many hues in small masses is agreeable.

Fragrance, also, is a quality to plan for in hardy borders,—here a bit of bergamot in a half-shady corner; there the stateliness and the sweetness of many lilies. The funkia scents the evening air, and the wild rose is as fragrant in foliage as in flower. There is added delight in the odorous quality of certain shrubs.

An interesting feature of the border is the seasonal succession of its bloom. It may begin before spring is more than an atmospheric hint, with its hepaticas, certain violets, and the snowdrops and crocuses. After that there need be no flowerless moment until a freeze—not a mere frost—stops the glow of the chrysanthemum and finishes the dainty display of the monkshood. The garden may also continue to please through ex-

tended weeks by changing foliage and by bared twigs of bright colors, as well as by glowing fruits that hang, like the barberries, until the next spring signals retirement.

A pleasing way of creating hardy borders is by the segregation of genera and families. Iris will cover four months with varied flowers of as varied heights. All the columbines may cover many weeks in time of beauty. A collection of viburnums makes a shrub border of long showiness. Lilies are gorgeous, or dainty; they are short or stately, and they include months of bloom-time as a family. There is great delight in studying plant families grouped in neighborly fashion.

The hardy border may endure full sun or deep shade, with all variations between, if its citizens are selected for their adaptability. Some plants of the border need wet feet; others are best, like the moss pink, on a dry and sterile sunny bank. It is this great range that makes the good border so very good, for it reflects the adaptability of nature for thousands of years.

The plants for a border are now legion. The nurserymen in these days have considered the needs of the planter, and there is little difficulty in securing what is wanted. Certain tradesmen grow perennials in small pots, available nearly all the growing season. But a personal hardy border can be made with little aid from the nurseryman. The man—or woman—who loves them can transplant hardy plants with success at any time of the year when the ground is not frozen deeply, and such persons find plants in the wild that may be separated without destroying colonies of a kind. There is also the fascinating and inexpensive method of growing the perennials from seed, resulting in more knowledge gained through failures; and in enough successes to furnish plenty of plants to the grower and his friends. The hardy border of the personal sort is a great educator in patience, perseverance and knowledge of plant life.

J. HORACE MCFARLAND.

### The making of the border.

Perennial herbaceous plants should form the major part of the planting in most borders, as these are permanent and eliminate the necessity of replanting the whole each year. Biennials, such as the Canterbury bells and foxglove,—for these are best treated as such,—

596. Border inclosing the back area of a city place, the central area being planted for shade.

hollyhocks and sweet williams are an essential that should be provided for in a reserve garden, and moved to the place in which they are desired to bloom as gaps occur. Annuals are necessary, such as mignonette, larkspur, candytuft, asters, stocks and other favorites to help out the display during July and August, for this is a period when perennials in bloom are scarce. There should be a background of shrubs with a group or individual dwarf shrub here and there to break up the flatness, especially in winter and early spring.

It is a question whether spring-flowering bulbs are admissible in this type of permanent border. It is better to keep them in a place by themselves for the reason that it is difficult to make changes when the ground is planted with bulbs, and to lift these at stated periods necessitates disturbing all the other occupants. A group of Darwin tulips here and there is much admired and in keeping, but a general planting is better made elsewhere, as under trees and among ferns.

A border being permanent, no effort should be spared to prepare thoroughly in the beginning. Deep-rooting plants, as peonies, hemerocallis, delphiniums and columbines, require deep preparation of the soil and liberal enrichment, double-digging or trenching being essential. It is better, if possible, to prepare and plant a portion at a time rather than to plant in a hurry and go over it all again later. If the soil is heavy, add sand and coal-ashes, so that it may be easier to work at all times. If the soil is inclined to be wet, it must be drained to take care of surplus water. A dry soil can be improved by the addition of leaf-mold, and provision

spaces, ample groups of each plant are necessary to secure the desired effect and to avoid "spottiness." Large-growing permanent plants, as peonies, boltonias, heleniums, rudbeckias and even silphiums and late-flowering asters should be planted at the back; in front of these, the phlox in separate colors, or at most two colors together that will harmonize, German iris in masses of one or more colors, bleeding heart, campanulas, *Veronica subsessilis*, monarda, oriental poppy, columbines, pyrethrums, perennial candytuft, and, in front of these, the usual dwarf edging plants, as arabis, alyssum, the Carpathian harebell, shooting-star, erysimum, *Tunica saxifraga*, geum, *Heuchera sanguinea* and others. If the border is narrow, individual treatment must be followed to secure a greater variety, and it is always permissible to add the old favorite sweet-smelling plants and herbs, such as balm, thyme, lemon verbena, southernwood, rosemary, rue, marjoram, borage and fennel, and some sweet geranium. All these give interest when flowers are waning, and call up associations helping to take the memory back to old friendships.

A border of this kind will need the addition of annuals to take the place of the earlier flowering plants that are past. Seeds of mignonette may be sown in the place where they are to flower; snapdragons may be raised in frames or hotbeds and set out among other plants that are passing; the scarlet salvia may be put where its color will not clash when in flower; gladiolus may be set out in groups of one color; *Hyacinthus candicans* looks well in fall when planted at the back; in fact, the mixed border of today should contain every desirable

plant that has either sentiment or blossoms — possibly both — to recommend it.

Lilies often do well in partially shaded situations in which moisture is sure and leaf-mold has been added. They should never be treated to manure. They are best seen when planted in masses sufficient to make a display in their season. *L. auratum* never lives long but is good for a year or two; *L. speciosum* is a better lily to keep; the tiger lily always remains with us as do also *L. umbellatum*, *L. Hansoni*, *L. Thunbergianum* or *L. elegans*; and great results are expected from the new Chinese *L. myriophyllum* and others of recent introduction. The flower-stalks of lilies should never be pulled up in fall, but cut off at the ground. It is a protection to the

597. A good mixed border, with many attractive plant forms.

must be made for watering in dry seasons. It is not necessary to lay the pipes deep if there is a natural pitch to the land, the water then being turned off late in the year and the pipes drained for safety. Faucets should be so placed that 50 feet of hose will water any part that needs it; thus the outlets may be 100 feet apart.

The grouping of plants in a mixed border is governed by the width and extent of this border. In large, wide

heart of the bulb to let the stem remain.

Perhaps the most important detail of the management of the border is that of protection in winter. The border should be protected and nourished at the same time; this is possible when a quantity of well-decayed manure and leaf-mold is available for a top-dressing, preferably after a little frost has penetrated the soil. This can be lightly forked into the soil in spring, but a spade should never be used except when making

changes. The great charm of this form of gardening is, after all, the necessity of change from year to year. It must not in any sense be considered changeless. Some plants will outgrow their allotted space and must be restricted, biennials will die out and need replanting, some color scheme may be wrong and need alteration, other really good things will need to be divided and replanted, and in this way the interest is kept up by the taking of notes through the season for reference at

is no more interesting phase of gardening than this, because it calls for care and study all the time, year by year, and our failures of this season are with us to profit by during the next.

E. O. ORPET.

BORECOLE: *Kale*.

BORÉTTA: *Dabæcia*.

**BORÒNIA** (after Francis Borone, an Italian who lost his life at Athens in the service of Dr. Sibthorp). *Rutææ*. Greenhouse shrubs, interesting, and very fragrant.

Boronia is a genus of Australian shrubs with numerous fls., having a rue-like fragrance: lvs. opposite, odd-pinnate, or simple: fls. axillary and terminal, red, rarely white or purplish, on the plan of 4, bearing a thick entire disk: fr. 2-4 carpels, each 1- or 2-seeded. *B. megastigma* and its allies, *B. elatior* and *B. heterophylla*, are remarkable for their very large stigma (which is 4-lobed at the base), and their curious stamens, 4 of which are small, yellow, pollen-bearing, and hidden under the stigma, while the 4 large, conspicuous ones are dark purple or black, and bear no pollen.—About 60 species, in Australia.

The chief value of boronias is their delicious fragrance. A small specimen will perfume a whole house for two or three weeks. Boronias are cultivated like Cape heaths in a cool greenhouse. After flowering they should be cut back, in order to make compact, bushy specimens. The leading shoots may be frequently pinched, to prevent a straggling growth. As most of them are native of barren sandy places, not bogs, good drainage is necessary. "Sour" soil is very disastrous to them. The English florists set their young plants in the open ground during summer, being careful to shade them with lath frames. Plants that have flowered two seasons are thrown away and replaced by younger specimens. They are propagated by cuttings from half-ripened wood inserted in 4-inch pots, which are filled to within an inch of the top with a compost of finely sifted loam, peat and sand, over which is spread a layer of sharp sand. After a thorough watering, they may be placed under a bell-glass in a greenhouse in which the temperature ranges from 45° to 50° F., and shaded from bright sunshine. Seeds germinate readily in the same temperature, and make good flowering plants in one season. Seeds can be obtained from German or Australian dealers, large quantities being collected in the wild. Boronias belong to a large class of hard-wooded Australian plants that were popular along with the Cape heaths in the early part of the nineteenth century. These were largely replaced by quicker-growing, soft-wooded plants. The renewed interest in boronias is largely due to the more recently introduced species, of which the first three described below are the best. American florists have lately grown them somewhat for Easter, especially *B. heterophylla*. Many species are likely to be introduced, as these shrubs are very brilliant in Australia, blooming when very young, and remaining attractive for two or three months.

599. *Boronia megastigma*. (× 1/2)

598. The single specimen set against a border planting.

the planting-time; and this is best done after the fall rains in September and early October before the soil loses its warmth, root-action being rapid then, and the roots soon become established before winter. There is always enough to do in spring, and changes in the borders left for that time are often made at the sacrifice of the display due in summer-time. Much misconception was the result of the term "perennial border." The plants were not all permanent, and the display was not continuous. Out of it has been evolved a much more satisfactory thing in that it calls for endless study, a greater variety containing all the good things, and the possibility of change each season as fancy dictates.

In wide borders especially, it adds greatly to the effect to plant some dwarf-growing shrubs near the path, such as Lemoine's deutzia and philadelphus, some specimens of the new choice lilacs (double and single), *Daphne Cneorum*, the dwarf flowering crabs like *Malus Torringo* and *M. Ringo*. These are all very beautiful and stand close inspection. The shrubs may be so arranged as to form bays for groups of plants, either for certain seasons or color effects, and if there is a tendency to outgrow the situation, pruning judiciously will help if done directly after the flowering season is past, with no sacrifice of bloom, always taking care to keep the individual shape of each shrub. Shears must never be used on shrubs, but shorten-in the longer shoots with a knife.

The Japanese iris, if used in the border, must be planted near water so they can be frequently irrigated in dry times or failure is sure to ensue. They are semi-aquatic and will take much nourishment also. The German kinds require a warm sandy soil, and a dry time in late summer suits them well. They are also best transplanted in September before the heavy rains, as root-action begins at this time and they become reestablished before the winter sets in.

Borders need constant care in summer to keep them trim and clean. All seed-stems and dead flowers should be removed, tall-growing plants staked up with neat stakes, and, above all, plants grown in reserve to take the place of such as are dying out after blooming. There

A. *Stigmas large*.

B. *Lvs. less than 1 in. long; lfts. in 1 or 2 pairs, plus an odd one.*

C. *Fls. borne singly.*

**megastigma**, Nees. Fig. 599. Height about 2 ft.: lvs. very sparse,  $\frac{1}{8}$ – $\frac{2}{3}$  in. long, sessile, the upper with 1 pair, the lower with 2 pairs of lfts. beside the end one; lfts. narrowly linear: fls. maroon-purple outside, yellow within, borne less densely than in *B. elatior*. At times some fls. are chiefly brown, others chiefly purple. B.M. 6046.—Var. *aurea*, Hort., has pale creamy yellow fls.

cc. *Fls. borne in whorls of 4 or 6.*

**heterophylla**, F. Muell. Height 5–6 ft. in Austra.: lvs. 1–1½ in. long, sometimes simple, usually with 1 pair, rarely 2 pairs, of lfts.: fls. bright scarlet, but usually pictured as purplish crimson. Differs from *B. elatior* and *B. megastigma* in its larger lvs., fewer lfts., more brilliant fls. and longer filaments. Cult. only in its var. *brévipes*, Hook. f., which differs merely in the shorter peduncles. B.M. 6845. Gn 32:442.—Of late years it has been grown for Easter by florists to a considerable extent.

bb. *Lvs. more than 1 in. long; lfts. in 2–6 pairs, plus an odd one.*

Drummondii*, Planch.). 2 ft.: lvs. pinnatifid: fls. rose-pink, freely produced in spring and summer. Var. *alba*. A white-fld. form is known. F. S. 9:881.

WILHELM MILLER.  
N. TAYLOR.†

**BORZICÁCTUS**: *Cereus*.

**BÔSEA** (after Kaspar Bose, German amateur of plants, at Leipzig, about 1700). *Amarantaceæ*. Syn., *Bosia*. Woody plants, rarely cultivated for their ornamental crimson berries.

Upright shrub: lvs. petioled, alternate, ovate to ovate-lanceolate, entire: fls. small, with 2–4 bracts at the base, in terminal spikes or racemes; sepals and stamens 5; petals wanting; ovary with 3 subulate stigmas: fr a 1-seeded berry.—Three species in the Canary Isls., Cyprus and Himalayas. They can be cult. only in warmer temperate regions. Prop. by seeds and probably by cuttings of young wood.

**Amherstiana**, Hook. (*Rodètia Amherstiana*, Moq.). Glabrous shrub: lvs. ovate, acute or acuminate, 3–6 in. long, narrowed at the base into a petiole  $\frac{1}{4}$ – $\frac{1}{2}$  in. long: fls. perfect, greenish,  $\frac{1}{2}$  in. across, sessile, with 2–4 bracts at the base, in terminal panicles: berries globose,  $\frac{1}{6}$  in. across, crimson. W. Himalayas.—Adv. as *Bohea Amherstiana*. The closely related *B. yervamdra*, Linn., from the Canary Isls., is sometimes cult. in Old World botanic gardens; it differs chiefly in its short-stalked, polygamous fls., with only 2 bracts at the base.

ALFRED REHDER.

**BOSTON FERN**: *Nephrolepis*.

**BOTANIC GARDEN**. A collection of growing plants, the primary purpose of which is the advancement and diffusion of botanical knowledge.

This purpose may be accomplished in a number of different ways, and by placing emphasis on different departments of the science. Some gardens, for example, are preëminently centers of systematic botany, or taxonomy; others of plant physiology and morphology; while in two or three cases, more than special emphasis is placed on botanical education, or formal instruction, as distinguished from, or in close connection with, research. But whatever the method, or wherever the emphasis, the aim is the advancement of botany as distinguished from horticulture or agriculture. Some of the ideas embodied in botanic gardens are displayed in Figs. 600–603.

All the scientific and educational work of a botanic garden centers around the one important and essential problem of maintaining a collection of living plants, both native and exotic. The extent to which this may be done depends largely on the local climate, and extremes are found in such gardens as Christiana, Norway, where the glasshouse is of prime importance, and Havana, Cuba, or Buitenzorg, Java, where the tropical climate renders a conservatory superfluous. At Buitenzorg there are coolhouses instead of hothouses.

Many ancient gardens were little more than olive orchards, and one of the earliest of these of which there is any authentic record is the temple garden of Karnak. There was recently discovered at Thebes the tomb of Nekht, the head gardener of this place, who is believed to have designed it during the reign of Thotmes III, about 1500 B. C.

While the early gardens

600. Entrance to botanic garden, Roseau, Dominica, B. W. Indies.

were cultivated largely for economic rather than ornamental purposes, yet the Greeks, as may well be expected, developed ornamental flower-gardens, and this idea, with so many others of Greek origin, was borrowed by the Romans. Among the best known of the Roman ornamental gardens were those of Lucullus, and of Pliny the younger.

We learn from Pliny that during the first century of the Christian era, Antonius Castor maintained in Rome a garden of medicinal plants. Four hundred years previous to this however, or about 350 B. C., a botanic garden was established in Athens by Aristotle. The first director of this garden was Theophrastus, a pupil of Aristotle, who fell heir to it on the death of the latter, and was able to improve it by means of funds supplied by a philanthropic citizen of Athens.

The gap between these more ancient gardens and those of today is, however, a wide one, and the modern botanic garden may be considered as more immediately derived from the private gardens of the herbalists in the sixteenth and seventeenth centuries. One of the best known of these was the garden of John Gerard, in Holborn. The plants here grown were chiefly medicinal herbs, and the study of these collections, together with the attempts to describe the plants accurately, gradually developed into modern systematic botany.

The organization of all modern botanic gardens is very similar in broad outline. There is usually a director, with a scientific staff, and a head gardener, with assistants. Some gardens are purely scientific institutions. Such were the early gardens of Michaux, in Charleston, South Carolina, of Darlington, in Chester, Pennsylvania, of Bartram, in Philadelphia, and of Hosack, in New York City, all long since extinct, and the Cambridge (England) Physic Garden. A large number of "botanical stations" and "acclimatization gardens" in the various colonies of European countries, the Desert Botanical Laboratory of the Carnegie Institution of Washington, at Tucson, Arizona, and the Acclimatization Garden of the same Institution at Carmel, California, all devoted entirely to scientific research, are often classed as botanic gardens, although not such in a strict sense of the term.

Many of the more purely scientific gardens are connected with universities, or other institutions of learning, or closely affiliated with them. This, for example, is true of the Hortus Botanicus at Amsterdam, where

universities of Bonn, Breslau, Göttingen, Halle, Munich, Strassburg, and Würzburg, in Germany; of Athens, in Greece; of Groningen, Leiden, and Utrecht, in Holland; of Genoa and Modena, in Italy; of Kiev, Odessa, and St. Petersburg, in Russia; of Basel, in Switzerland; of Nikko and Tokyo, Japan; and in the United States, those of the University of California (Berkeley), Harvard University (Cambridge, Massachusetts), Smith College (Northampton, Massachusetts), Mt. Holyoke College (South Hadley, Massachusetts), Michigan Agricultural College (Lansing), the University of Michigan (Ann Arbor), the University of Minnesota (Minneapolis), the University of Pennsylvania (Philadelphia), and Johns Hopkins University (Baltimore).

It is not uncommon in European countries to find botanic gardens in connection with gymnasia (high schools), and normal schools, but the only instance of this kind in the United States, known to the writer, is the botanic garden of the Michigan State Normal School, at Ypsilanti. This garden, with an area of 3 acres, serves only the purpose of supplying study-

were conducted the epoch-making experiments of De Vries with the evening primrose, *Enothera Lamarckiana*, and other species, culminating in the elaboration of the mutation theory, giving a new stimulus to studies in experimental evolution and plant-breeding, and incidentally illustrating now studies in pure botanical science, made primarily for their own sake, and seeming, at first thought, ever so academic or impractical, may be of inestimable value to such applied sciences as horticulture and agriculture.

Among other botanic gardens forming an integral part of the organization of collegiate or university departments of botany may be mentioned those of Aberdeen, Dundee and St. Andrews universities in Scotland; those of Birmingham, Cambridge and Oxford universities, and of the Royal Agricultural College at Cirencester (Gloucester), in England; that of Trinity College (Dublin), in Ireland; those of the universities at Budapest, Czernowitz, Krakau, Lemberg, Prag, and Vienna, in Austria-Hungary; of Ghent and Liege, in Belgium; of Copenhagen, in Denmark; of the Catholic university, in Lille; and the medical college and the veterinary college in Lyons, France; those of the uni-

versities of Bonn, Breslau, Göttingen, Halle, Munich, Strassburg, and Würzburg, in Germany; of Athens, in Greece; of Groningen, Leiden, and Utrecht, in Holland; of Genoa and Modena, in Italy; of Kiev, Odessa, and St. Petersburg, in Russia; of Basel, in Switzerland; of Nikko and Tokyo, Japan; and in the United States, those of the University of California (Berkeley), Harvard University (Cambridge, Massachusetts), Smith College (Northampton, Massachusetts), Mt. Holyoke College (South Hadley, Massachusetts), Michigan Agricultural College (Lansing), the University of Michigan (Ann Arbor), the University of Minnesota (Minneapolis), the University of Pennsylvania (Philadelphia), and Johns Hopkins University (Baltimore).

It is not uncommon in European countries to find botanic gardens in connection with gymnasia (high schools), and normal schools, but the only instance of this kind in the United States, known to the writer, is the botanic garden of the Michigan State Normal School, at Ypsilanti. This garden, with an area of 3 acres, serves only the purpose of supplying study-

Other so-called botanic gardens are little more than public pleasure parks. Golden Gate Park, the municipal park of San Francisco, and primarily a pleasure park, is administered with some regard to scientific ideas, and is sometimes referred to as a botanical garden. Here, also, for example, may be classed Prospect Park, in Brooklyn, in which the labeling of the trees gives a somewhat botanical aspect to the place. This park is said to contain more different species of trees, both native and foreign, than can be found elsewhere in America outside of a true botanic garden or arboretum.

A third type of garden combines the features of a scientific institution for research and education with those of a public park. Of this nature are the Kew

Gardens, near London, the Jardin des Plantes, Paris, the Berlin Botanic Garden, at Dahlem, the New York Botanical Garden, in Bronx Park, the Missouri Botanical Garden, St. Louis, the Botanic Garden of the Imperial University, at Tokyo, Japan, and the new Brooklyn Botanic Garden.

It has already been implied above that the early study of botany was closely connected with the use of plants for medicine, gardens being largely, or even exclusively, devoted to growing medicinal herbs. In this connection it is interesting to note that while the staple food, fodder, and fiber plants are grown as crops, pharmacists and physicians have, with few exceptions, such as the opium-poppy and the ginseng, always depended upon wild plants. This practice of gathering only wild herbs doubtless accounts in large part for the well-known and, until recent date, quite general adulteration of drugs.

The total number of botanic gardens outside the United States is approximately 325. In our own country there are about sixteen, eleven of which are college and university gardens. The following foreign gardens are referred to in the order of their establishment.

#### *Foreign gardens.*

1. Pisa, Italy, founded in 1543, by order of the Grand Duke Cosmo de Medici I. The second director of this garden was Cæsalpino, after whom the leguminous genus *Cæsalpinia*, was named. This was one of the earliest gardens devoted to the public study of botany.

2. Muséum d'Histoire Naturelle, Paris, founded in 1635 by Guy de la Brosse, physician to the king. Its first name was Jardin Royal des Plantes Medicinales, which was changed to the present name in 1790. The gardens proper occupy 14 hectares out of a total of 23.

3. Chelsea Physic Garden, London. Established by the Society of Apothecaries, in 1673, for the stated purpose of furthering the teaching of botany, and of providing material and opportunity for botanical research. The educational and scientific influence of this garden can hardly be overestimated. It was founded by the Society of Apothecaries of London, in 1606, and originally comprised the Grocers' Company, an ancient guild. In 1617 a new charter was granted by James I, and the Society of Apothecaries became separate from the Grocers' Company. From the start the Society was active in advancing botanical knowledge, and soon after its incorporation, field trips, called "herbarizings," were held at irregular intervals, and to these irregular trips a regular annual one was added about 1633. The botanical interests and activities of the Society found natural expression in 1673 in the establishment of the Physic Garden. At first the ground was utilized not only for growing specimens for scientific study, but also for growing crops of medicinal plants sufficient to furnish crude drugs for the commercial use of the Society. However, when Sir Hans Sloan, in 1722, deeded to the Society additional ground, adjacent to the original 4 acres of the garden, in the terms of the deed was a prohibition of this practice, and the garden became from thenceforth devoted to investigation and instruction.

The garden entered upon a new epoch with the appointment, as "gardener," of Philip Miller, well known as the author of the classic "Dictionary of Gardening." The title of "gardener" was subsequently changed to "curator." In 1681 steps were taken toward the development of a botanical library, which, by 1769, contained about 300 bound and unbound books, dealing chiefly with botany. In 1835 John Lindley was appointed Director of the Garden.

It was in connection with the Society's endeavor to grow successfully plants that could be grown only with difficulty or not at all in the smoky atmosphere of London that the well-known "Wardian case" was devised, by Nathaniel Bagshaw Ward, Fellow of the Royal

Society, and a friend and patron of the Physic Garden. These "closely-glazed cases" were first described by Ward in a letter to Sir William Hooker, dated 1834, and published in the "Companion to the Botanical Magazine," in May, 1836. It was also found possible, by employing these cases, to ship living plants across the tropics from the southern to the northern hemisphere with the loss of scarcely a plant, whereas, under former methods of shipment many more plants perished than survived.

Among many important publications growing out of the work of the Chelsea Physic Garden or produced by members of its staff, may be mentioned Curtis's "Linnaeus's System of Botany," and his "Botanical Magazine," and "Flora Londonensis;" Lindley's "Flora Medica," and Lindley and Moore's "Treasury of Botany;" Miller's "Gardeners' Dictionary," mentioned above; and Hudson's "Flora Anglica." In 1902 a well-appointed laboratory building was opened in the garden. In this building are two small rooms which contain the private library of Charles Darwin. The library equipment is used by students of the Royal College of Science, and the Professor of Botany of the college is Scientific Advisor to the Committee of Management. The garden is used freely and largely by teachers with classes, and living material for class study is supplied in quantity to the University of London, the Royal College of Science, and other local schools.

4. Royal Botanic Gardens, Kew, London (1759). The present gardens resulted from the fusion of two royal estates, the Richmond Gardens and the original Kew Gardens. Richmond Gardens, composing the western portion of modern Kew, were the grounds of the royal residence of Edward I. The second half was the private grounds of Kew House. Lord Capel, who, by marriage, came into possession of Kew House in 1696, was greatly interested in the cultivation of plants, and his collections formed the nucleus of the modern Kew plantations. The property was leased to Frederick, Prince of Wales, about 1730, and after his death, his widow, Princess Augusta of Saxe Gotha engaged, in 1759, William Aiton, a former pupil at the Chelsea garden, to establish a physic garden; its rank as a true botanic garden may be considered to date from this year. The union of Richmond and Kew was effected in 1802.

Under Aiton was inaugurated the plan of sending out expeditions for botanical exploration in foreign countries, a practice which has greatly enriched the herbarium and living collections, and which has been carried out on a large scale and with similar results in America by the New York Botanical Garden. Perrédès states that the specimen on which L'Héritier founded the genus *Eucalyptus* was collected on one of these expeditions to the Cape in 1772. In 1789 Aiton published his now classic "Hortus Kewensis." He was succeeded in the directorship by his son William T. Aiton, and the latter, in 1841, by Sir William J. Hooker, although Aiton retained directorship of the pleasure-grounds until 1845.

Hooker's aims were to make Kew so attractive as to create in the general public an interest in plants, to advance pure and applied botany, and to train collectors and gardeners. The area of the garden has increased from 15 acres, when Sir William Hooker became director, to about 95 acres at the present time. The former pleasure-grounds are now developed and known as the Arboretum. In 1875, on the retirement of Sir J. D. Hooker, who succeeded his father in 1865, Sir William Turner Thistle-Dyer was appointed director. The present director is Lieut.-Col. Sir David Prain.

In scientific matters the power of the Director of Kew is absolute, but in matters of administration, he is under the governmental Board of Agriculture. The library consists of about 20,000 volumes, over one-half

of which are set apart, primarily in the office of the Keeper of the museums.

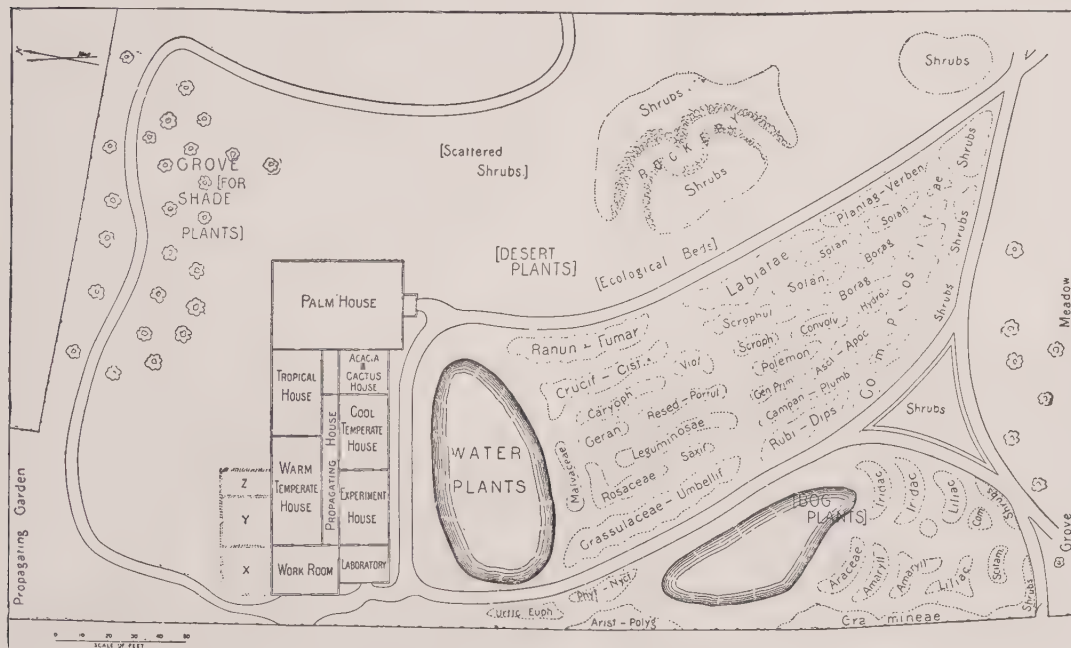

Kew has throughout exerted a profound influence on the development of botanical science, and by the training of gardeners, and in numerous other ways, has forwarded and really made possible the development and work of the numerous colonial gardens and botanic stations. The latter are in reality experiment stations, and while administered by the colonial office, depend upon Kew for scientific advice and for much economic plant material. Consult *Arboretum*.

5. Royal Botanic Society's Gardens (1740). Special mention should be made of the Royal Botanic Society's Gardens at Regent's Park, London, since so much attention has been given there to the various aspects of horticulture. Prior to being taken over by the Royal Botanic Society, about 1840, the area of the garden was occupied by a nursery. Originally flat and circular in outline, it has been given, by artificial treatment, a diversified topography, and the plantations include an

A practical gardening school was established in 1897, and in 1902 a laboratory building was erected for the use of the school. A portion of the grounds is also set aside for this school, and the head of the gardening staff is the chief instructor in the gardening school. Occasional exhibitions are given to illustrate the nature-study work of local schools.

The work of the garden in supplying study-material for schools is unusually extensive, from 50,000 to 60,000 specimens of living plants being supplied annually to students. Several hundred students' tickets are issued each year by teachers in various schools. These tickets admit the bearer daily until three o'clock, after which hour the garden is closed to all except Fellows and other visitors.

The grounds are leased from the Crown, and the money for this and other purposes is derived entirely from private subscriptions by Fellows of the Royal Botanic Society. On this account provision is made to provide attractions for those not primarily or entirely

602. Plan of a small botanic garden.—Smith College, Northampton, Mass. Early plan.

American garden (which is said to be now restricted to a planting of rhododendrons), an herbaceous garden, and an economic garden. Much attention is given to the growing of medicinal plants. An arboretum was started, but eventually abandoned on account of the small area.

The arrangement of plants in the herbaceous garden is that devised by Marnock, the first curator, and the one who planned the entire garden. Each of the different-shaped beds is devoted to one family of plants, so that the relative size of the families is seen at a glance, and beds of nearly related families are grouped together. The economic division comprises trees and shrubs, but the economic herbaceous plants are included in the general herbaceous garden. This is the most extensive exhibit of economic plants grown in London, and it is said that the first banana ever tasted by the late Queen Victoria came from a plant in this garden.

The main part of the conservatory, built in 1845, was the first large plant-house of glass and iron to be erected in England. The system of heating is that of hot water, and the pipes are underground, but this arrangement has not proved to be economical.

interested in botany. The attractions include a tennis-court, croquet-ground, flower-shows, garden fêtes, and a club-house.

There is a set of meteorological instruments in the garden, and records of barometer, wet- and dry-bulb thermometers, temperature of the soil at depths of 1 foot and 4 feet, maximum temperatures in sun and shade, minimum temperatures in shade and "on grass," precipitation, wind direction (but not velocity), duration of sunshine, and general remarks are published in the Botanical Journal of the Society. This journal, issued quarterly, is now (1912) in its second volume.

6. Buitenzorg (1817). The botanic garden at Buitenzorg is known officially as 's Lands Plantentuin (Botanic Garden of the State). Its Latin name, "Hortus Bogorensis," is derived from Bogor, the native name of Buitenzorg. The garden is a division of the governmental Department of Agriculture of the Dutch East Indies, and has been described as the most beautiful botanic garden in the world. It was established in 1817 by Reinwardt, and is located 36 miles from Batavia. This location was fortunate for climatic rea-

sons, for while on the Java east coast there is a drought season of three to four months, there is no drought season at Buitenzorg. The total annual precipitation is between 180 and 200 inches, or approximately five times that of New York State. The incessant rains are accompanied by a general lowering of the temperature, and this makes possible the cultivation of plants from the higher altitudes. The altitude of Buitenzorg is 900 feet. There are in reality three gardens: First, the botanic garden proper, in the center of the city, with an area of 89 acres. Each division of this garden has a blanket label, giving a list of the genera it contains, and each species is represented by two specimens, one of which bears a label, giving the scientific name, the common name, if there is one, and usually the economic products of the plant. The climbing plants are arranged systematically in a group by themselves. The vast majority of plants are arborescent, and there are about 10,000 species cultivated. The garden is open day and night. The second division is the agricultural garden, about a league from the center of Buitenzorg, and having 173 acres. Only plants of economic importance, including medicinal plants, are grown here. The third division or garden is some distance from Buitenzorg, on the slopes of the volcano of Gede. Its area is 74 acres, and its altitude is 5,000 feet, thus making possible the cultivation of plants that cannot be grown in the other two gardens. There is a museum building in connection with the garden proper at Buitenzorg.

"The Annals," the well-known publication, was founded by the third director, Scheffer.

#### *American gardens.*

1. Bartram's Garden (1728). The first botanic garden in America was that of John Bartram, established in 1728, and still existing, although in a greatly modified form. At about the same date (1725), Robert Prince, one of the early settlers on Long Island, began to raise a variety of trees for the purpose of ornamenting his own grounds, and this activity soon developed into a nursery, ultimately well known, not only in America, but throughout Europe. Such a venture was favored by a growing interest in ornamental and edible plants resulting from the importation of various French fruits by the Huguenots, who settled at New Rochelle, New York, and along the north shore of Long Island. This nursery continued under the supervision of the same family for five generations (130 years). For a number of years the proprietors confined their attention to fruit trees. The institution was visited by President Washington, and on August 29, 1796, after the battle of Long Island, the British General Howe placed a guard around the garden to protect the trees and plants until all danger was passed. In many old English gardens today are numerous native American plants derived from the Prince nurseries. In 1793 the nursery was christened the Linnæan Botanic Garden, and a catalogue of plants here grown passed through more than twenty editions. The mahonias,

603. Entrance to a botanic garden (or arboretum), showing the utilization of natural features and woods as well as planted specimens.

Under the directorship of M. Treub, the garden became a mecca for investigators from all over the world. One large laboratory is reserved entirely for the use of visiting botanists. In the herbarium the sheets are not kept in folios as ordinarily, but in tin boxes, a necessary protection against insects and excessive moisture. There is a library of several thousand volumes. The director distributes annually, under the authority of the government, and free of charge, seeds and plants of useful vegetables.

described in some of the earlier manuals as "from Oregon," are said to have been first grown in the Linnæan garden, being one of the many novelties received from the Lewis and Clark expedition. One of the plant-houses was devoted to camellias, one to azaleas, one to oranges and lemons, one to African and Asiatic plants, and two to miscellaneous collections. The proprietors were ever alert for novelties, and at the time of the potato famine in Ireland, Prince paid \$600 for less than a pint of bulbs of *Dioscorea Batatas*, for the pur-

pose of testing them as a possible substitute for the Irish potato. At one time there were over 100 varieties of strawberries under cultivation here, including the once famous Isabella, which originated as a chance seedling or mutant in the garden of Isabella Graham, in Brooklyn. While not a botanic garden in the modern or scientific sense, the Linnaean garden exerted such a profound influence on American horticulture and arboriculture that it should not be entirely passed over in this place.

2. Evans's Garden (1828). The garden of John Evans is located along Ithan Creek, near Philadelphia, within walking distance from Rosemont Station, on the Pennsylvania Railroad. It was established about 1828, and was one of the fruits of Bartram's garden. Evans frequently visited the Bartram garden and other gardens in Philadelphia and vicinity, and became greatly interested in plants. His father was a miller, and the vicinity of the mill, with the creek and mill-pond, and the diversified land adjacent, afforded a wide range of habitat conditions. Evans corresponded with Sir William Hooker and exchanged seeds with him, as well as with the son, Sir Joseph Hooker, including material collected by the latter in the Himalayas. He also had a correspondent in Germany. In Evans's garden the plants were arranged almost entirely on an ecological basis, in "the order of nature," and in this respect it differed materially from most other gardens before or since. Mr. Evans was his own director, curator, and head gardener, doing most of the manual labor in the garden himself. It is of interest to note here that he used sawdust from his father's mill to kill the weeds around the cultivated plants, and this, on decaying, made a rich fertilizer, which was spaded under. The garden is said to have been, in its prime, practically unrivaled in shrubs and trees, and to have had few equals in the richness of its herbaceous material. Many of the trees and shrubs were labeled with lead labels, but no catalogue of the collections was ever published.

3. The Missouri Botanical Garden (1859). The Missouri Botanical Garden, at St. Louis, was established by a gift of money and land from Henry Shaw. It is popularly known in St. Louis as "Shaw's Gardens." On November 6, 1885, Mr. Shaw established the Henry Shaw School of Botany as a department of Washington University, at St. Louis, and the garden and school became closely affiliated. The professor or one of the professors in the school shall be director or director's assistant, or both. The grounds were formerly closed to the public on Sundays, except the first Sunday of June and September, but since 1912 they have been open every Sunday afternoon from April to December. Each year there is preached in a local church a sermon on "the wisdom and goodness of God as shown in the growth of flowers, fruits, and other products of the vegetable kingdom." The first director of this garden was William Trelease, who resigned in 1912, and was succeeded by George T. Moore. The grounds comprise about 45 acres, the herbarium about 800,000 sheets, and the library about 50,000 books and pamphlets. One of the features of the garden is a vegetable-garden, which gives pupils practice in the growing of vegetables, and, by means of a forcing house, this work is continued throughout the year. The best-known publication is the Annual Report. "The Missouri Botanical Garden Bulletin," established in January, 1913, will hereafter contain the annual reports of the officers of the board and the director, while the volume hitherto known as the "Annual Report" will in the future be devoted exclusively to the results of scientific research carried on at the gardens.

4. Elgin Botanic Garden (1801). The first botanic garden in New York City was located on Murray Hill, about 1656, and was the precursor of the Elgin Botanic Garden, established in 1801, by David

Hosack, on 20 acres of ground, located at what is now the northwest corner of Fifth Avenue and 47th Street. This garden was transferred to New York State in 1810, and became known as The Botanic Garden of the State of New York. It was later transferred to Columbia University, but finally abandoned for lack of funds. In the spring of 1913 the area was sold by the university for \$3,000,000.

5. New York Botanical Garden (1894). The present New York Botanical Garden, established in 1894, is located at Bronx Park, in the Borough of the Bronx, New York City. It comprises an area of approximately 250 acres, and besides two extensive ranges of plant-houses, a range of six propagating-houses and the plantations, includes the largest purely botanical museum in the country, if not in the world. On the third floor of the museum building are located the herbarium, library and laboratories. The grounds, conservatories, and museum are open daily without charge. The present Director-in-Chief, N. L. Britton, is also Professor of Botany in Columbia University, and has served since the foundation of the institution. Under the auspices of this garden, the director and members of the staff have conducted a systematic exploration of continental and insular America, the results of which are being embodied in the "North American Flora," the most extensive botanical work ever undertaken in America, appearing at intervals in fascicles or parts. The herbarium, composed of the herbariums of Columbia University, the Torrey Botanical Club, and that of the garden proper, contains over 1,500,000 specimens, and the library has over 40,000 volumes and pamphlets. The scientific policy of the institution is directed by a Board of Scientific Directors, and the financial administration by the Board of Managers of the Trustees. The scientific staff comprises (1912), besides the director-in-chief, an assistant director, a head curator, four curators, two assistant curators, head gardener, director of the laboratories, bibliographer, librarian, and other officers. Free public lectures on botanical and closely related subjects are given on successive Saturday afternoons, and the following publications are issued: "Journal" (monthly), "Mycologia" (bi-monthly), "Bulletin" (irregularly, and containing the Annual Report), "North American Flora," Memoirs, and Contributions. The Garden is supported by municipal and by private funds.

6. Brooklyn Botanic Garden. The Brooklyn Botanic Garden, established in 1910, is a department of The Brooklyn Institute of Arts and Sciences, and an outgrowth of the work of the Department of Botany of the Institute. It was the wish of the founders to develop an institution that, in connection with research, would place more than usual emphasis upon formal instruction in botany. It is also the intention to emphasize chiefly departments of botany other than taxonomy, such as plant physiology and ecology, morphology, and pathology, experimental evolution, and plant-breeding. The first and present director is C. Stuart Gager. The new laboratory and instruction building, in process of erection (1912), will contain offices of administration, several large laboratories, a small herbarium room, a library, physiological and photographic darkrooms, and twelve private research rooms. A range of plant-houses is also under construction. The grounds comprise about 43 acres, located in the heart of the borough of Brooklyn. Through the center runs an artificial brook, with swamp. The plantations are classified under ten heads, as follows: (1) Systematic Section, comprising hardy herbaceous plants, chiefly perennials, not native within 100 miles of the Garden, and arranged in beds according to their natural affinities. (2) Local Flora Section (Native Wild-flower Garden), containing herbaceous and woody plants growing without cultivation within a radius of 100 miles of the Garden (the Torrey Botanical Club Range). The strictly native

sorts are designated by labels of different color from those of introduced species. (3) Morphological Section, with divisions of (a) External Anatomy and (b) Comparative Morphology. (4) Ecological Section, adjacent to and including the swamp section of the brook and extending back to include a dry knoll. Here is illustrated the adjustment of plants to environmental influences. (5) Evolution Section, illustrating such subjects as variation, inheritance, artificial and natural selection (including the origin of horticultural forms), struggle for existence, and survival of the fittest. (6) Economic Section with divisions of (a) Foods and Condiments, (b) Medicinal and Poisonous Plants, and (c) Fiber Plants. (7) Weed Section, to show the botanical characteristics of weeds, as bearing on their economic significance. (8) Formal Garden Section, in front of the laboratory building and greenhouses, and serving to illustrate the uses of plants, chiefly horticultural, for purely ornamental purposes. (9) Arboretum, a collection of trees, chiefly native. (10) Fruticetum, a collection of shrubs, both native and exotic. The arboretum and fruticetum features are developed in close connection with the other sections, and in the systematic garden the aim has been to group the shrubs and trees as near as practicable to the herbaceous material with which they are most closely related. The willows and alders are grown along the brook.

The Garden issues an administrative quarterly, "The Brooklyn Botanic Garden Record" (the April number of which contains the Annual Report), Contributions, and Guides. A series of Memoirs and of Educational Leaflets is also projected. Admission to the grounds is free daily, including Sundays and holidays, from 8 A.M. until sunset. The Garden is supported by annual municipal appropriations, by the income from an endowment, amounting at present to over \$50,000, and by gifts.

#### *Suggestions from the foregoing.*

As may be inferred from what has preceded, the history of botanical gardens has shown a steady progressive development from collections of medicinal herbs, gathered and studied with reference to their economic uses, to institutions endeavoring to maintain collections of all kinds of plants, both herbaceous and woody, some ornamental and useful, but perhaps most of them collected and studied for their own sake, from the standpoint of pure science, with an endeavor to understand the nature as well as the uses of plants. The Chelsea Garden affords a concrete illustration of this, for while the collections here were at first almost entirely confined to medicinal plants, these now form only a comparatively small portion of the collections. In this way, and in this way only, may botanical science be most rapidly and most surely advanced, to the advantage not only of pure science itself, but of horticulture, agriculture, forestry, pharmacology, and all phases of applied botanical science.

It was one of the marks of greatness and of sound judgment of Sir William Hooker, that he aimed definitely to make Kew Gardens not only a scientific institution of the first rank, but to make them beautiful,—attractive to the general public. This latter aim has been too often neglected or minimized, on the theory that a botanic garden is a scientific institution, and should, therefore, be developed with little regard for the non-scientific public. This is an unfortunate and unfair attitude, unfair to the general public, especially in those gardens which are supported in part by public money, and unfortunate for botanical science because it not only neglects a very important aspect of botany—applied botany,—but loses the opportunity of enlisting the intelligent sympathy of the community with botanical endeavor. Many persons who might otherwise remain quite indifferent to botanical work in general, or even to the work of a given garden in particular, may, through being attracted primarily by

the beauty of the collections and grounds, be led to give generous support to such work, or even to discover that their own main interest is botany, and ultimately to advance the science by their own studies.

It is unfortunate that the United States government has no national garden to do for our own country what Kew has done for England. The climate and location of Washington combine to make the capital city an admirable place for the development of a botanic garden, and two or three branch gardens could be established to advantage in parts of the country, giving wide diversity of climatic conditions, such as one of the extreme southern states, the great American desert, and one of the most northern states.

With only very little additional expense, many city parks could be made more interesting and instructive, and none the less beautiful and attractive, by giving portions of them more the character of a botanic garden, at least by suitably labeling the trees and shrubs and growing them with some regard to botanical affinities.

With the exception of the Missouri Botanical Garden, there is nowhere offered in the United States a thorough course of study for the purpose of training gardeners to take charge of botanic gardens. The training received in a few months' experience with a commercial florist or seedsman is not sufficient, nor do horticultural courses in our agricultural colleges answer the purpose. Botanic gardens need for gardeners, and especially for head-gardeners, men whose training has included not only instruction in the care and management of greenhouses, and in plant-propagation and cultivation, but also a thorough laboratory course in the elementary principles of botany, a course in systematic botany, including the collection and identification of a minimum number of wild plants, an elementary course in plant pathology, with emphasis on methods of treatment, a course in the physics and biology of soils, and also in such specialized work as accessioning and labeling. The general education of men for these positions ought also to be such as to enable them to express themselves well in writing, and to give courses of instruction to others in the various practical phases of their work, such as greenhouse economy, plant-propagation, and the care of herbaceous and woody plants out-of-doors. The recent success of a number of popular books on gardening indicates a rather widespread demand for such information on the part of amateurs and people of comparative leisure, as well as others. It is much better to get this information in connection with the actual operations of a scientifically administered botanic garden, rather than by the wholly inadequate method of reading a book on the subject.

C. STUART GAGER.

**BOTANY.** The science that treats of plants; plant-knowledge. In its widest sense, and properly, it includes much that, by common consent, is usually included in

604. *Botrychium obliquum*. ( $\times \frac{1}{2}$ )

horticulture,—as amelioration of plants by domestication, hybridizing, and the like. Horticulture is a part of the large conception of botany, so far as its scientific aspects are concerned.

**BOTRÝCHUM** (Greek, in allusion to the grape-like sporangia). *Ophioglossaceæ*. A genus of mostly temperate plants allied to ferns, with fleshy roots, short underground sts., each of which bears a single free-veined lf., consisting of a short petiole, a usually triangular, divided blade, and a single erect panicle bearing the fleshy sporangia.

These plants may be grown in the hardy border, or against a building on the shady side. They require no special treatment. They are little cultivated, but are of interest to the collector or fancier.

**virginiánum**, Swartz. **MOONWORT**. Six in. to 2 ft. high, with a broad, triangular blade, with 3 main triquadri-pinnatifid divisions: fertile portion long-stalked. E. U. S.—The only species large enough to make a display.

AA. *Petiole much shorter than fertile portion.*

**obliquum**, Muhl. Fig. 604. Plant, 6–15 in. high, with a ternate blade 2–6 in. wide: segms. obliquely ovate or oblong,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long: fertile part long-stalked. (*B. ternatum*, Authors, not Swartz, which latter is a different Japanese species.) E. U. S.

**disséctum**, Spreng. Plant, 6–18 in. high, with a ternate, finely dissected blade, 3–8 in. wide, the ultimate divisions  $\frac{1}{10}$  in. or less wide. E. U. S.—Evergreen; delicate and graceful. Grows in woods and meadows.

R. C. BENEDICT.

**BOTTLE-BRUSH**: *Metrosideros*; also *Callistemon* and *Melaleuca*.

**BOTTOM HEAT**. Soil temperature that is higher than that of the superincumbent air. Most tender plants require to have the roots warmer than the tops, particularly when grown under glass.

**BOUGAINVILLEA** (De Bougainville, 1729–1811, a French navigator). *Nyctaginaceæ*. South American shrubs, often climbers, with very gaudy large bracts, grown under glass, and as arbor plants South.

Leaves alternate, petioled, entire: fls. small and inconspicuous, tubular, the margin 5–6-lobed; stamens, 7–8, on unequal capillary filaments; ovary stipitate. The small and inconspicuous fls. are inclosed with large and showy magenta-purple or red bracts that constitute the decorative value of the plants. Two more or less scandent species are chiefly known in cult. Less than a dozen recognized species.

The bougainvilleas have been much grown of late as pot-plants. The young stock (started from cuttings) may be grown in the field and be lifted in early autumn; this will produce plants for spring bloom but not for early flowering. For earlier bloom, the plants may be carried through the summer in pots. Half-ripened or old wood, in 6- to 12-inch lengths, may be used for cuttings in April to June. The subsequent culture is simple. For glasshouse work the plants may be kept cut back and the branches trained. In California, Florida, and other southern regions, bougainvilleas are plentifully used as porch-covers, where they make a most brilliant show. Not hardy.

The cultural requirements of the bougainvilleas are of the easiest. They thrive in almost any kind of soil and should be grown in full sunshine. *B. glabra* and its varieties are the best for ordinary purposes, as they bloom when small, and thrive readily in a cool greenhouse or in the open where free from frost. *B. spectabilis* and its var. *lateritia* require more tropical conditions and reach large dimensions. All are readily propagated, and will root in a few weeks from cuttings of

the young shoots a few inches in length and placed in sandy soil in bottom heat and moisture at a temperature of 65° or 70° F. *B. glabra* and its varieties make most excellent pot-plants, either as large or small specimens. They are also valuable for summer bedding. All the kinds make very desirable subjects for clothing verandas, arches and pergolas or for planting at the base

605. *Bougainvillea glabra*. ( $\times \frac{1}{2}$ )

of trees (where the climate is suitable for outdoor culture), which they will rapidly clothe in a mass of most beautiful and highly colored flower-bracts. Another and most effective purpose to which these plants can be put is that of hedge or fence plants in tropical and subtropical countries. They stand drought exceedingly well and may be pruned with impunity. (C. P. Raffill.)

**glabra**, Choisy. Fig. 605. Grows 10 and more ft. high and wide, when planted in the ground and allowed to have its way; glabrous: lvs. ovate and acuminate, glabrous and bright green; bracts cordate-ovate, bright rosy red, distinctly veined. Brazil. G.C. III. 23:168; 30:265. Gn. 54, p. 257; 64, p. 353. R.H. 1889:276. A.G. 16:15. A.F. 11:1371. F.E. 10:106.—Free-flowering and handsome; often grown in pots and kept dwarf. Var. **Sanderiana**, Hort. Very floriferous, blooming even in very small pots. Gn. 45:418. A.F. 10:307; 11:977; 12:1185. Gng. 4:281; 5:345. G. 27:457.—A very worthy plant both for pot culture or as a shrub or climber. Often blooms when 1 ft. high, but reaches a height of 10–20 ft. Var. **Cypheri**, Hort. A much larger and finer plant than the type; the large and bright-colored deep rose bracts are freely produced in long plumose clusters on all the principal growths, and are more highly colored than those of the var. *Sanderiana*. It may be treated the same as var. *Sanderiana* as to cult. It is an acquisition as a decorative plant. Var. **variegata**, Hort. Lvs. prettily variegated with creamy white; useful as a neat and quick-growing foliage plant for summer bedding.

**spectabilis**, Willd. (*B. speciosa*, Lindl. *B. splendens*, Hort.). Taller and stricter, with larger and thicker lvs., hairy: fls. in large panicles; bracts larger, deep rose-color, but varying to purple and greenish. Brazil. B.M. 4810, 4811. P.M. 12:51. I.H. 42:30.—An immense and strong-growing climber, rising by means of numerous stout hooked spines. Variable; known also as *B.*

*brasiliensis*, *B. bracteata* and *B. peruviana*. Var. *lateritia*, Lem. (*B. lateritia*, Hort.), has brick-red bracts. I.H. 13:466. More showy than the last when in full bloom; perhaps distinct; said to be more difficult to start from cuttings than the type, at least without bottom heat.

*B. aurantiaca*, Hort. = *B. Lindleyana*. — *B. formosa*, Bull. Semi-scandent, free-flowering; purplish mauve; under comparatively cool treatment said to be well adapted for decoration of warm green houses and conservatories. Brazil. — *B. Lindleyana*, Hort. Hairy, climbing, with strong curved spines; lvs. obovate-rounded, acute, slightly undulate, very hirsute; bracts elliptic, short-acuminate, cinnabar-color. — *B. refulgens*, Bull. Lvs. pubescent; racemes long and drooping, and bracts purple. Brazil. Apparently a less valuable and shy-flowering form of *B. spectabilis*.

L. H. B.

606, 607. Flower theme (at the left) and foliage theme (at the right). In Figs. 606-616, the outline circles represent flower masses, and the black circles foliage masses.

**BOUQUETS.** The aim in flower-arrangement is beauty: (1) A display of the natural beauty of the plant, or (2) the creation of a beautiful group of floral material.

(1) Plant beauty combines two chief elements: color and form. In such plants as the pansy, the peony, and the full-blown rose, color is the dominant element. In such plants as the calla, the Easter lily, and many of the orchids, form is the dominant element. In some flowers, as rosebuds, nasturtiums, and chrysanthemums, the two elements are so nearly balanced that either one may be selected for special display. In any case, one element, color or form, should predominate in the arrangement. Plate XVIII shows at *a*, the yellow-centered daisy massed to emphasize its beauty of color; *b* shows the same flower arranged to display its beauty of form. A single clump of the plant has been transplanted to a bowl, that its wayward natural growth in the midst of the grasses may be enjoyed.

In some cases the flowers may be the theme. The arrangement then becomes similar to Fig. 606. (In all the figures the dotted circles indicate flower masses, and the solid black circles, leaf masses.) In others the foliage may be worthy to become the theme, or may be used as a foil to bring out more clearly the exquisite grace or hue of a few flowers. In such a case Fig. 607 represents the type of arrangement. Foliage and flowers should never vie with one another for first place.

Color flowers may be massed. The bigger the bunch of peonies, the more impressive and splendid is the color. Form flowers should not be massed. A single stalk of Easter lilies is enough. When massed, the marvelously graceful lines of leaves and flowers are lost.

608. Harmony in vase and bouquet.

609. Harmony in vase and bouquet.

Receptacles should always be less attractive than that which they hold. Brilliant colored vases, those with gilding, cut glass, vases decorated with pictures, or with flowers modeled in high relief or represented in color, are all to be avoided. They are too obtrusive. They force the flowers to take second place. Receptacles of clear glass which take on the color of the stems put into them, of dull soft colors, of unpolished metal, are likely to be most serviceable in displaying the natural beauties of flowers.

The receptacle should be of the shape best adapted to holding the flowers as nearly as possible in the position in which they grew. In Plate XVII at *d*, the broad bowl (full of pebbles to steady the stems) makes possible such an arrangement for the apple blossoms. The tall vase with the narrow neck, at *c*, insures the right position for the spray of bayberry.

Of course the natural beauty of a plant cannot be displayed to advantage when confused with other plants. This is the reason for the general rule: Use in a bouquet only flowers of one kind, with their own foliage.

(2) Beautiful groups of plant forms present, (*a*) unity, (*b*) rhythm, and (*c*) balance.

(*a*) An arrangement has *unity* when all the parts of which it is composed are so related that the whole makes its appeal to the eye first. All the parts must have something at least in common to bind them together. In nature the common element may be *texture*, as in the snakeroot; *color* as in the mullein; *line* as in the goldenrod. In flower-arrangement the receptacle must have some element in common with the plant; in *a* (Plate XVIII) the color of the jar echoes the color of the flowers; in *b* both the color and the ornament of the bowl echo the character of the sod; in *d*, the shape of the bowl echoes the shape of the apple blossom and its color echoes their color. In *c*, the shape of the vase echoes the shape of a bayberry leaf; its contours echo the lines of the stems; its pattern echoes the speckle of the bayberries; and the dark stand gives the receptacle a color repeating the dark color of the leaves. The receptacle must have something at least in common with the plant, but must never vie with it in any way. If the bouquet is tall and slim, the vase may have similar form (Fig. 608); if it is short and broad, the vase may repeat that shape (Fig. 609). In Fig. 610, the sprays have one line in common, a simple forceful curve repeated in the vase. In Fig. 611, the sprays have the reversed curve in common, echoed softly in the vase.

(*b*) *Rhythm* means orderly variety of some kind. Fig. 612 exhibits orderly variety in the sizes of leaves, all subordinate to the one flower. Such an effect can always

610, 611. Simple and reversed curves.

612, 613, 614, respectively, showing simple rhythm forms.

H  
T  
B  
..

XVII. The arrangement of bouquets.

be produced by pruning the spray. Fig. 613 shows an orderly variety in sizes in both leaves and flowers. The parts are in pairs, a larger and a smaller composing each pair like march time in music. Fig. 614 shows an orderly variety in which each set is composed of a series of three, large, smaller, smallest,—something like a three-part measure, waltz time, in music. Figs. 610 and 611 show rhythm of measure in the lengths of the sprays and rhythm of line in their curves. In each case there are three similar curves, but three which form a series from least bent to most bent. Fig. 608 presents a rhythm of measure in the sizes of the flowers, another in the sizes of the leaves, and another in the lengths of the stems. Fig. 615 shows a rhythm of color. When flowers of one kind present a wide range of tone,—pinks, for example, running from white to red through various tones of pink, they may be arranged agreeably by making evident the rhythm of color from lightest to darkest. When the flowers vary in hue as nasturtiums do, from yellow through orange to red, a rhythm of hue may be established in a similar way. Such sequences of color (unless too formal) are always more pleasing than haphazard spottings of color. All these arrangements show rhythms of mass. Fig. 608, 610, and 611 show a triple subdivision, large, smaller, smallest, but not so disconnected as to destroy the unity of the whole in any case. Figs. 609, 615, and 616, show more complex rhythms of mass, but in a general way they present a simple movement from the diffuse to the compact. This the eye can take in at a glance. Each review of this rhythm gives additional pleasure to the sense of sight. A rhythm, an orderly sequence of some kind, for the eye to follow, is essential in floral arrangement.

615. A color rhythm.

(c) *Balance*.—A flower-arrangement must not be too formal. It must present something of the freedom of wild nature but it must appear to be in stable equilibrium. Every spot, every color, every stem line, every space between these elements, presents an attraction for the eye. All these attractions must be adjusted to one another so that the whole appears to stand securely. This means that the parts must be disposed with reference to the vertical center line of the vase. The principle is that of the steelyard. A large, a brilliant, a solid mass, near the center line, may be balanced by a small, a dull, or a diffuse mass, farther removed from the center line. To appear free, like nature, the attractions on one side must not duplicate, in form, size or position, the masses on the other. Such an arrangement is formal, and belongs in the realm of structural and conventional art; but, however varied the elements may be, they must be so disposed as to counterbalance each other, and maintain the balance of the whole. Compare the illustrations with this principle in mind.

Lovers of natural beauty do not overlook the possibilities of winter bouquets. Sprays of seed packs, withered leaves, and the like often present soft dull colors in such harmonious groups of tones that they may serve as models for color schemes for cos-

tumes and the interior decoration of rooms. They often present exquisite rhythms of measure, subtle refinements of line, charming combinations of erratic curves, and surprising oppositions of harmoniously related details, unrivaled in the growing period of the plant's life. Plate XVIII shows at *e* a picturesque spray of white oak with "oak apples."

More than one kind of plant may be used in an arrangement, provided the beauty of one enhances the beauty of the other, like day and night, like a handsome man and a beautiful woman side by side. But even then the two must have something in common. The Japanese often combine a round-leaved plant with a linear-leaved plant. While presenting a contrast in form the two have green in common. Nature often combines strong contrasts, as in the dark green holly with its bright red berries. While the colors are complementary, the textures are alike. Both present smooth surfaces with glints of light in common. Moreover the red never vies with the green in mass. It is a green spray, with a few precious red dots.

In a word, in good flower-arrangement either beauty of color or beauty of form is the dominant element. The whole arrangement presents a unity within which play rhythms of measure, of line and of tone, all related to a principal mass, the supreme center of interest, and all so disposed as to constitute a balanced whole.

HENRY TURNER BAILEY.

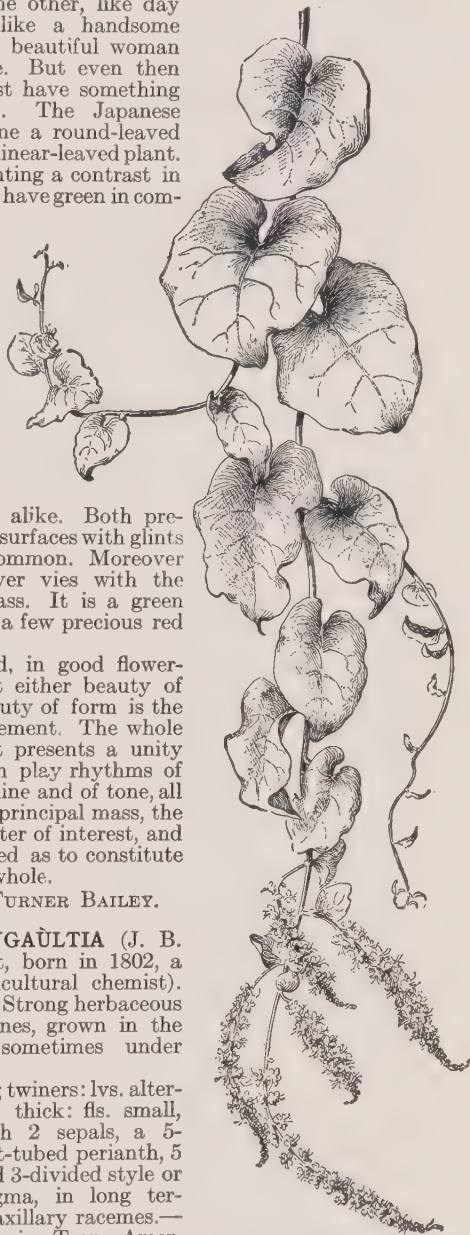

**BOUSSINGAULTIA** (J. B. Boussingault, born in 1802, a famous agricultural chemist). *Bassellacææ*. Strong herbaceous perennial vines, grown in the open and sometimes under glass.

Branching twiners: lvs. alternate, entire, thick; fls. small, perfect, with 2 sepals, a 5-parted, short-tubed perianth, 5 stamens, and 3-divided style or 3-lobed stigma, in long terminal and axillary racemes.—Ten species in Trop. Amer. *Anredera* is a related genus.

**baselloides**, HBK. MADEIRA VINE. MIGNONETTE VINE. Fig. 617. Perennial, root tuberous: sts. smooth, reaching 10–20 ft. in a season, and in late summer or fall bearing profusely of the fragrant white fls. (which become nearly black with age), and producing little tubercles by means of which the plant is prop. Ecuador. B.M. 3620.—A common

616. Complex rhythm of mass.

617. *Boussingaultia baselloides*. ( $\times \frac{1}{2}$ )

vine, prized for porches and arbors. The roots are stored in the winter, and planted out after danger of frost is past. The plant will not endure frost. Sometimes grown in the conservatory and window-garden. It has run wild in Fla. and Texas. L. H. B.

**BOUVÁRDIA** (Charles Bouvard, 1572–1658, physician to Louis XIII, and Superintendent of Royal Gardens in Paris). *Rubiaceæ*. Handsome greenhouse

618. The common garden form of *Bouvardia*. Cluster from a side growth.

flowering shrubs, once popular as florists' plants.

Small shrubs (rarely perennial herbs), with simple, sometimes verticillate, lvs. and subulate stipules: fls. in terminal cymes, showy, in red, yellow and white; calyx 4-lobed, the lobes persistent; corolla long-tubular or salver form, with 4 spreading lobes; stamens 4, alternate with corolla-lobes and attached in the tube or throat; styles inserted or exserted in different fls., the stigmas 2; ovary 2-celled: fr. a loculicidal caps.—About 30 species, from Texas and Ariz. to Colombia and southward, chiefly in Mex. and Cent. Amer.

Bouvardias were once very important florists' flowers, but they have now given place, along with camellias and others, to chrysanthemums, carnations and other plants. The plants have such merit in themselves, however, and are so likely to return to favor in this country, that a rather full cultural treatment is here given. The bouvardias of florists do not represent any of the type species. They are sports, hybrids, and other types of variations. The Latin-form names in American trade catalogues nearly all belong to these garden forms. The species which are of most importance to the horticulturist are mentioned below:

A. Fls. in shades of red.

B. Lvs. normally in 3's (except, perhaps, on the branchlets).

**triphylla**, Salisb. (*B. Jacquinii*, HBK.). Small pubescent shrub, 2–6 ft. high: lvs. in 3's or 4's (or opposite on the branchlets), lanceolate to lance-ovate, glabrous above: fls. an inch long, pubescent, bright scarlet. Mex. and reaching north to Ariz. B.M. 1854; 3781 (as *B. splendens*, Graham).—The genus *Bouvardia* was founded upon this species, which was intro. into England more than 100 years ago. It is evidently the most important parent strain, although it is probably not in cult. in its original form. Figs. 618 and 619 partake very strongly of this species. In fact, Fig. 618 compares well in botanical characters (except less long-pointed lvs.) with the early pictures of *B. triphylla*.

**leiántha**, Benth. Much like *B. triphylla*; more bushy and better grower: sts. hairy: lvs. hairy above: fls. glabrous. Mex. R.H. 1851:81.—Perhaps only a form of the preceding. It is said that the first recorded hybrid bouvardia appeared about 1857, with Mr. Parsons' nurseries at Brighton, England, being between *B. leiántha* and *B. longiflora*. Many secondary forms have come from this cross, some of them being white, as *B. Davidsnii* or *B. Vreelandii* (G. 27:632).

Other red-fl. 3-lvd. species are: *B. angustifolia*, HBK. Lvs. lanceolate, revolute, glabrous above and fine-pubescent below: branches nearly glabrous. Mex. *B. hirtella*, HBK. Very similar: lvs. pubescent on both

surfaces. Mex. *B. scabra*, Hook. & Arn. Lvs. ovate, short-stalked: fls. large in dense clusters, pink: st. hairy. Mex.

BB. Lvs. opposite.

**Cavanillesii**, DC. (*B. multiflora*, Schult.). Hairy: lvs. ovate-acuminate, broad at base, short-stalked, edges hairy: fls.  $1\frac{1}{2}$  in. long, very slender, glabrous. Mex.

AA. Fls. yellow.

**flava**, Decne. Lvs. opposite, ovate-lanceolate or lance-elliptic, very short-stalked, ciliate: fls. very long drooping, in 3–5-fl. racemes, bright yellow. Mex. F.S. 1:43.

AAA. Fls. white.

**longiflora**, HBK. Glabrous, branching shrub: lvs. opposite, ovate-acuminate, stalked: fls.  $1\frac{1}{2}$ –2 in. long, with a very slender tube and a wide-spreading, large limb, 2 or 3 together and aggregated into a terminal cyme. Mex. B.M. 4223. F.S. 2:123.

**Humboldtii**, Hort. Lvs. opposite, ovate-acuminate: fls. very large, fragrant, in a large, terminal cluster. G.C. 1873:717. G. 27:331 (var. *grandiflora*).—This is a choice conservatory plant. It is usually catalogued as *B. Humboldtii corymbiflora*. Blooms from summer to winter. Probably a derivative of *B. longiflora*. *B. candidissima*, Hort., white-fl., is said to be a hybrid, with *B. Humboldtii* as one of its parents.

**jasminiflora**, Hort. Compact and dwarf, very floriferous, the fls. in close, terminal clusters. G.C. 1872:215.—Probably a derivative of *B. longiflora*. L. H. B.

All the cultivated species and varieties of bouvardia are evergreen greenhouse plants. They thrive best in a mixture of equal parts of rich turfy loam, leaf-mold and sand, which should be rammed moderately firm but not too hard. They require an abundance of water during the growing season, and, once they have started into growth in the spring, should never be allowed to suffer for the want of water at the roots. A house in which the temperature can be maintained at 55° F. with fire-heat, suits them best, but the temperature may, with advantage, be allowed to run up to 80° or

619. The double-flowered form of the garden *Bouvardia*. Terminal truss.

90° F. with sunheat, providing they are given an abundance of ventilation at the same time. The plants should be frequently syringed during the growing season to keep down insect pests and to help to maintain a healthful growing atmosphere. All the bouvardias revel in a fair amount of sunshine, and may be described as sun-loving plants, but under glass during the hottest part of the day, it is an advantage to shade them lightly to break the direct rays of the sun. Under this

treatment growth is rapid, and the plants require to be frequently pinched back at the points in order to induce sturdy, well-balanced specimens. If this pinching-back is neglected, the plants will become ill-balanced and few flowers will be the result. The time of flowering can be readily regulated by the time of the last pinching back, and a succession of flowering plants may be maintained practically throughout the whole year. Amongst market-growers, the aim should be to secure the bulk of the flowers in the winter period, for which purpose very little pinching of the shoots should be practised after September, and the plants should then be allowed to grow on until the flowers appear. When in flower, the plants should be removed to a somewhat drier house, and they last much longer if kept in a temperature of about 50° F.

Many growers plant out strong healthy plants upon benches under glass, or in favored situations outdoors. Under these conditions growth is rapid, and if carefully watered and attention is paid to pinching-back the leading growths, fine flowering specimens are quickly secured. For the cut-flower trade, this method has a considerable advantage over pot culture. All through the growing period, it is absolutely essential that the plants should never be allowed to suffer for the want of water and, when well established, they should be fed liberally with manure.

Specimens planted out in the open, should be lifted with a good ball in early autumn, potted up and placed in a close shaded house until the roots again become active. These plants will furnish a large supply of flowers during the winter months.

After the flowering period is over, bouvardias should be kept somewhat cooler and drier at the roots for a few weeks, after which they should be cut back and started again in heat and moisture. If kept frequently syringed, they will soon break freely and furnish a good supply of cuttings. These are best removed with a heel when about 2 inches long, and placed in 4- or 5-inch pots in an open compost of equal parts sand and peat or fine leaf-mold, and placed in a moist and close frame with a brisk bottom heat. Roots are soon emitted, when the plants should be potted up singly and moved on into larger-sized pots as required. Most of the garden varieties are also readily propagated from pieces of the larger and thicker parts of the roots in spring. These may be cut into lengths of about 2 inches and planted the same as cuttings, leaving a small piece exposed above the soil. Adventitious shoots are soon formed on these and soon make good serviceable plants.

The numerous garden forms are all so distinct in habit, shape and poise of the flowers from all the known species, that it is difficult to identify any of them as varieties of any one species. It is probable that they are complex hybrids of *B. triphylla*, *B. leiantha*, *B. Cavanillesii*, *B. scabra* and possibly *B. flava*, all of which species are more or less villose and scentless. The garden forms are extremely handsome, and useful as cut-flowers, for indoor decoration, also for button-holes and for making up into ladies' sprays, wreaths and so on. Other purposes for which they are largely

grown, are the decoration of the greenhouse or conservatory, and, in warm localities, as bedding plants. A selection of some of best varieties is given herewith:

*Alfred Neuner*. Double, pure white fls.; an old variety of great merit; of good constitution. *Bridal Wreath*. White, free-flowering, with large loose trusses; one of the best for cut-fls. *Bridesmaid*. Double, pink fls., brighter than President Garfield. *Brilliant*. Bright crimson, floriferous, and of easy cult. *B. candidissima*. White; an improvement on *B. jasminoides*. *Dazzler*. Rich scarlet; free and compact-growing. *B. elegans*. Scarlet; large truss of loose habit. *B. flavescens*. Light yellow; distinct; bad habit. *B. flavescens flore-pleno*. Double form of last-named. *Hogarth*. Brilliant scarlet; large truss; a well-known variety. *Hogarth flore-pleno*. Double, scarlet. *B. jasminoides*. White; a free-flowering dwarf form, of easy cult. *King of the Scarlet*. Light-scarlet; large truss of very fine large fls.; a new variety of great merit. *Maiden's Blush*. Light rose; floriferous. *Mrs. Robert Green*. A fine salmon-pink sport from President Cleveland; distinct and beautiful. *President Cleveland*. Brilliant scarlet, with crimson tube; the richest and best of its color, floriferous and of easy cult. *President Garfield*. Double, pink; floriferous; large truss. *Priory Beauty*. Delicate rose or deep pink; one of the most beautiful; elegant habit; medium and compact truss. *Purity*. White; fragrant, free, large fls.; loose truss. *Sang Lorraine*. Bright vermilion-scarlet; double. *The Bride*. White, tinted with pink; one of the best for bouquets, etc. *Thomas Meehan*. Double, bright scarlet, with pale rose-scarlet tube; floriferous. *Triomphe de Nancy*. Double bright orange-red; large truss; distinct. *Victor Lemoine*. Large, very double fls.; brilliant scarlet. *B. vreelandtii* (*B. Davidsonii*). Pure white; extremely floriferous; a favorite variety in gardens, and of very easy cult. *Vulcan*. Scarlet; medium-sized truss. *White Bouquet*. Pure white; exceedingly dwarf and compact.

C. P. RAFFILL.

620. *Bowiea volubilis*.

**BOWENIA** (bears the name of Sir Geo. F. Bowen, once Governor of Queensland). *Cycadaceæ*. Zamia-like plant, grown to some extent in Florida and hardy in the central part.

*Bowiea*, a monotypic genus, differs from *Macrozamia* in foliage characters and in the absence of a point on the cone-scales; and from *Zamia* largely in its bipinnate lvs. *B. spectabilis*, Hook. Trunk thick, scarcely rising above ground, plant glabrous: lvs. 3-4 ft. long, loosely bipinnate, each pinna or lft. 1 ft. or more long, the 9-20 segms. ovate or ovate-lanceolate, oblique or falcate, acuminate: cones short-peduncled, the sterile ones 1½-2 in. long and half as thick, the fertile ones 3-4 in. diam., and the scales expanded between the seeds into a broad and thick truncate apex. Queensland, Austral. There is a var. *serrulata*. B.M. 5398, 6008.—This charming little cycad makes beautiful

clumps, thriving well under lath houses in Fla., when given proper shade, good supply of moisture and soil rich in humus; the lvs. are easily broken if the plant is roughly handled.

L. H. B.

**BOWIEA** (after J. Bowie, collector for Kew). *Liliacæ*. A monotypic genus containing one of the most curious plants in the vegetable kingdom, sometimes grown under glass as an oddity, and as an illustration to students of botany.

A round, green bulb 4-5 in. thick throws up yearly a very slender, twining fl.-st. 6-8 ft. high, with many compound, forked, curving branches below, and numerous small green fls. above. This branched fl.-stalk is green and performs the function of the usually absent lvs.; somewhat asparagus-like. There are no lvs. except 2 small, linear, erect scales at the apex of the bulb, which quickly vanish. The lvs. show its relation to *Drimys* and *Scilla*.

*volubilis*, Harv. Fig. 620. Perianth 6-cleft to the base, persistent, green or greenish white, the segms. incurved at the tips, ultimately reflexed. S. Afr. B.M. 5619.—Sold by dealers now and then, and cult. in botanic gardens with cactus-like euphorbias and other curiosities. *B. volubilis* is a remarkable bulbous-rooted twining greenhouse climber. The bulbs grow to be very large, sometimes becoming 19 in. circum. and some 6 or 7 in. deep. The slender, twining vine seems out of proportion to the size of bulb. It does not produce lvs., but the lower part of the vine is furnished with pendulous, abortive panicles which seem to perform the function of lvs. The small insignificant greenish white fls. are borne at the upper end of the vine. This is a useful plant for twining on the supports of a moderately warm greenhouse, and is of the easiest possible cult. Prop. is effected by seeds, or occasionally by the natural division of the bulbs. The season of growth usually begins about the first of Oct., when the bulbs should be repotted in any light, rich soil, and kept well watered until the sts. begin to mature, which usually occurs in May, when water should be gradually withheld, and the plants stored away in some shaded part of the greenhouse and kept quite dry until the season of growth begins again.

WILHELM MILLER.  
E. J. CANNING.

**BOWKÈRIA** (Henry Bowker and sister, botanists in S. Afr.). *Scrophulariaceæ*. South African shrubs of 5 species, one of which is rare in cult. in south of England, and likely to be intro. into this country. Allied to *Scrophularia*, differing in being ligneous and in technical floral characters. *B. Gerrardiana*, Harv. (*B. triphylla*, Hort.). Erect-branched shrub, 8–10 ft., with gray hairs: lvs. in 3's, sessile, elliptic or oblong-lanceolate, 4–6 in. long: fls. in small axillary cymes, 1 in. across, satiny white, calceolaria-like, red-dotted inside, the upper lip flat, lower lip shorter and ventricose and 3-lobed. B.M. 8021. G.C. III. 36, Suppl. Dec. 10.—Hardy in the Isle of Wight.

BOX: *Buzus*.

**BOX ELDER** (*Acer Negundo*, which see). A very popular small native tree for planting on the prairies and in trying climates. It propagates most readily from seeds. It is an excellent nurse tree for other species. The wood is of inferior quality. It grows with great rapidity for a few years.

621. *Brachycome iberidifolia*.

**BOYKÍNIA** (named after Doctor Boykin, of Georgia). *Thérofon*, Raf. *Saxifragaceæ*. Glandular-pubescent perennial herbs, 7 species, of which one is Japanese and the others in the S. Alleghany region and Calif., two of which have been offered for wild gardens. Lvs. alternate, but mostly radical, stalked, blade orbicular

or very broad and lobed or cleft: fls. white, small, in terminal clusters; petals 5, entire or nearly so; stamens 5; styles 2–3: fr. an urn-shaped or globose caps., erect or pendulous. Mostly mountain plants. *B. rotundifolia*, Parry. Villous-pubescent, 2–3 ft., leafy: lvs. 2–4 in. across, orbicular or broadly ovate, crenately cut and toothed: fls. short-pedicelled, on one side of the branches; petals little surpassing the acute calyx-lobes. Water-courses, San Bernardino Mts. *B. aconitifolia*, Nutt. Erect, 1–3 ft.: lvs. 2–6 in. across, nearly orbicular or reniform, palmately 5–7-lobed: fls. in a glandular-pubescent corymb; petals eroded; sepals triangular-ovate. Mt. slopes, Va. to Ga.—A pretty foliage plant for wild gardens and borders.

L. H. B.

**BRACHYCHÆTA** (Greek, *short bristle*). *Compositæ*. A monotypic genus, growing in open woods from Ky. to N. C. and Ga. Closely allied to *Solidago*, from which it differs in the very short pappus (the bristles shorter than the achene), and the lower lvs. cordate. *B. cordata*, Torr. & Gray (*B. sphacelata*, Brit.), which has been intro. by dealers in native plants, is 2–3 ft. high, soft-pubescent, with thin, serrate, ovate to orbicular-ovate lvs.: fls. golden yellow, in small heads, which are borne on the thyrsoid, secund branchlets; disk-fls. perfect.—Recommended for the native border, particularly in half shade.

**BRACHYCHILUS** (*short lip*, the labellum being suppressed). Spelled also *Brachychilum*, from the name as a subgenus of *Hedychium*. *Zingiberaceæ*. Herbaceous plants of two species, one or both of which have been cultivated abroad, in warmhouses. Closely allied to *Hedychium*. The species are *B. Horsfieldii*, Peters (*Hedychium Horsfieldii*, Wall.), from Java; and *B. tenellum*, Schum., from Moluccas. The former has been cultivated as *Alpinia calcarata*.

**BRACHYCHITON** (name referring to the short imbricated hairs and scales). *Sterculiaceæ*. Australian trees (about eleven species), grown to some extent in Florida and perhaps elsewhere South, often included with *Sterculia*, from which they differ (when the genera are distinguished) by bearing the radicle next the hilum in the seed, having the seeds and inside of carpels villous, and other technical characters.

Leaves entire or rarely lobed: fls. unisexual or polygamous, in panicles or racemes; calyx with 5 or 4 spreading lobes; petals wanting; stamens 10–15 in a column united with the pistils; ovary with 5 nearly or quite distinct carpels, the styles united under the pelate or lobed stigma.—Two showy-fl. species are reported in this country. *B. acerifolium*, Muell. (*Sterculia acerifolia*, Cunn.). Large timber tree in its native country: lvs. long-stalked, 5- or 7-lobed, 8–10 in. across, the lobes oblong-lanceolate or almost rhomboid: fls. rich red, in loose racemes or small panicles; calyx  $\frac{3}{4}$  in. long, glabrous, broad-lobed; ovary borne on a short stalk or column: fr. large follicles, long-stalked, glabrous. *B. diversifolium* may be either *B. diversifolium*, R. Br. = *Sterculia caudata*, Heward; or *B. populneum*, R. Br. = *S. diversifolia*, Don, probably the latter and here described: tree, 20–60 ft., glabrous except the blossoms: lvs. long-stalked, ovate to ovate-lanceolate and entire, or more or less deeply 3- or 5-lobed: fls. yellowish white, reddish within, in axillary panicles that rarely exceed the lvs.; calyx broadly campanulate, about  $\frac{3}{4}$  in. diam., acutely lobed to middle: follicles nearly ovoid, sometimes 3 in. long, on stalks 1–2 in. long. Both species are reported as growing vigorously in high pine-land garden in Fla.; trunk unusually thick near the ground; characteristic in the open cone-like tops.

L. H. B.

**BRACHYCÔME** (*short hair*, from the Greek, alluding to the pappus). *Compositæ*. About 40 species of Australian herbs, with membranaceous involucrel

bracts, naked pitted receptacle, very short pappus bristles, and diffuse leafy growth, one of which is cult. as a garden annual; of very simple cult.

**iberidifolia**, Benth. SWAN RIVER DAISY. Figs. 621, 622. A very graceful little annual (6-16 in. high), suited to borders, and also attractive in pots; seeds may be sown in the open or under glass: fls. blue, rose or white, an inch across: lvs. small, pinnate, with narrow divisions. H.F. 4:96. J.H. III. 54:461. V. 3:170. A good winter-bloomer 4 or 5 mos. after sowing.

L. H. B.

**BRACHYSÈMA** (short standard, referring to the flower). *Leguminosæ*. Shrubs or undershrubs, Australian, making good pillar or climbing plants for greenhouse; allied to Baptisia and Thermopsis.

Evergreen: lvs. opposite or alternate, simple, sometimes reduced to scales: fls. red or yellowish or almost black, solitary or several together or sometimes crowded on short radical scapes, the keel turned upward by the curving of the pedicels; stamens not united with each other: fr. ovoid or elongated, turgid.—About 14 species, a few of which are known in gardening literature. **B. acuminatum**, Truff. (*B. speciosum*, Hort.), is now offered as a good red-fl. pillar plant: sub-frutescent: lvs. opposite, oval-elliptic, entire, more or less narrowed to base and short-petioled, the older ones long-acuminate: fls. deep carmine-red to nearly purple, in short axillary clusters, the corolla much exceeding the yellow-green calyx, the standard very small. R.H. 1866:413.—An attractive free-flowering species.

L. H. B.

**BRACHYSPÀTHA**: *Amorphophallus variabilis*, *A. Titanum*, and others.

**BRADLÈIA**: *Phyllanthus* and *Wisteria*.

**BRÀHEA** (Tycho Brahe, the Danish astronomer). *Palmaceæ*, tribe *Corypheæ*. Medium-sized, usually spineless palms except on the leaf-stalks, with ringed trunks, the upper part of which is usually clothed with the persistent leaf-bases.

Leaves usually numerous, nearly round and somewhat peltate, the many lfts. plicate and deeply 2-parted, sometimes slightly spiny on the margin, more often filamentous; petioles flattened, dentate or rarely spiny along the margins, very fibrous at the sheathing base: spathes usually linear, firm, almost woody, frequently perfectly glabrous; spadix much branched, sometimes twice or thrice paniculate and bearing among the dense white wool 1 or many sessile fls. in each cluster; fls. hermaphrodite, sometimes with inconspicuous bracts, 3 nearly round sepals, 3 valvate petals and 6 stamens: fr. small, ovoid, sometimes pubescent. Beccari admits only 4 species, all Mexican except *B. salvadorensis*. From its nearest horticultural relative, Sabal, Brahea is distinguished by the purely technical character of having 3 free carpels.

In a moderately warm house, the cultivated braheas

will thrive very well. A mixture of sand, rich loam and well-rotted horse- or cow-manure is best. They require plenty of water. They are not very common in the trade but two species are grown outdoors in southern California. Propagation is by seeds, which are rare.

*A. Fls. solitary on the spadix.*

**dúlcis**, Mart. PALMA DULCE. Sts. several in a cluster, 10-20 ft., 6-8 in. thick, cylindrical: lvs. 4-5 ft. long; petiole plano-convex, green, with pale margins; ligule short, nearly triangular, green, the scarious villous margin at length deciduous; lfts. 36-50, linear, acuminate: spadix 6-8 ft., pendulous from among the lowest lvs., much branched: fr. edible. Mex. I.H. 10:379.

**calcàrea**, Liebm. (*B. nitida*, André). Trunk 8-15 ft. high, covered with the woody persistent lf.-bases: lvs. usually 20-30 in a dense bushy crown, unarmed, membranaceous, covered below with a brownish powder: spadix long, more or less erect and considerably longer than the lvs., after flowering more or less pendulous; fls. solitary, with a single bract: fr. ovoid. Mex. R.H. 1887, p. 344. Gn. 35, p. 285.—Offered by Montarioso Nursery.

*AA. Fls. in more or less dense, though small, clusters on the spadix.*

**Pimo**, Becc. St. 8-12 ft.: much the same as the last in general appearance and vegetative characters: spadix 3-4-branched, the finer ramifications very slender and bearing small clusters of whitish yellow fls.; stamens 6, forming by union a 6-lobed ring: fr. unknown.—A rare Mexican species, known in the trade only at Santa Barbara, Calif.

*B. edulis*, Wendl., sometimes offered in Amer., is *Erythea edulis*, Wats.—*B. filamentosa*, Hort.=*Washingtonia filifera*, Wendl.—*B. filifera*, Hort.=*W. filifera*.—*B. glauca*, Hort.=*Erythea armata*, Wats.—*B. robusta*, Hort.=*Washingtonia*.—*B. Roëzlii*, Lindl.=*Erythea armata*, Wats.

N. TAYLOR.

**BRÀINEA** (C. J. Braine, Hongkong). *Polypodiaceæ*. One species related to Woodwardia. Lvs. in a crown, 1-pinnate, the venation as in Woodwardia, consisting of a single row of areoles along each midvein with free simple veins extending to the margins: sporangia along the free veins, not reaching the margin, without indusium.

**insígnis**, J. Smith. A beautiful small tree fern from S. E. Asia. Requires rich soil, moisture and shade.

R. C. BENEDICT.

**BRAKE**. A name applied to various coarse ferns, particularly to *Pteris aquilina*.

**BRAMBLE**. Thorny plants of the genus *Rubus*,—raspberries, blackberries, dewberries.

**BRASÈNIA** (meaning unexplained). *Nymphaeaceæ*. WATER-SHIELD or -TARGET. One species of aquatic plant widely distributed (in N. Amer., Asia, Afr., Austral.). Lvs. oval, entire, floating, centrally peltate; submerged parts coated with thick transparent jelly: fls. axillary near the summit of the st., small ( $\frac{1}{2}$  in.), purple; sepals 3 or 4; petals 3 or 4, linear; stamens 12-18, on filiform filaments; carpels 4-18, separate, forming indehiscent 1-2-seeded pods. **B. Schrèberi**, Gmel. (*B. peltata*, Pursh. *B. purpurea*, Casp.), is not a showy plant but is interesting and suitable for edgings of small aquatic gardens. Grows in 1-6 f. of water. Easily prop. by division of roots or by seed.

H. S. CONARD.

**BRASSÁVOLA** (A. M. Brassavola, Venetian botanist). *Orchidaceæ*. About twenty tropical American epiphytes, closely allied to *Lælia*, and demanding similar treatment.

The fls. are large, solitary or racemose, the sepals and petals narrow and greenish, the lip white: lvs. thick, solitary. For the cultivator, the treatment of *Brassavola* is identical with that of the Mexican *Lælias*. Plenty of sun to mature the young growths, and water

622. *Brachycome iberidifolia*.  
(Natural size.)

when growing, with a somewhat drier atmosphere when resting, will be found to suit them. Suspend on blocks. *B. Digbyana*, Lindl., is *Lælia Digbyana*; *B. glauca*, Lindl., is *Lælia glauca*.

A. *Fls. solitary.*

B. *Lvs. long and narrow: lip fimbriate-toothed.*

**cucullata**, R. Br. (*B. cuspidata*, Hook.). Lf. terete and subulate, grooved above: scape very short but bearing a very long-tubed fl., so that the blossom seems to be elevated on a st.; sepals cream-colored, tinged red; petals white; lip 3-lobed, fimbriate, the middle lobe beak-like. S. Amer. B.M. 543, 3722. G.W. 11, p. 556. Gt. 1, p. 324. O.R. 10:265.

623. *Brassavola cordata*. ( $\times \frac{1}{2}$ )

BB. *Lvs. short: lip entire.*

**acaulis**, Lindl. & Paxt. Low: lvs. very narrow: fls. large, greenish white; lip cordate; tube red-spotted at base. Cent. Amer.

AA. *Fls. in racemes.*

B. *Blade of lip not longer than claw.*

**cordata**, Lindl. Fig. 623. Lvs. linear, rigid, recurved: fls. corymbose; sepals and petals lance-linear, acuminate, pale green; lip roundish-cordate, cuspidate, entire, scarcely as long as the claw. Jamaica, Brazil. B.M. 3782.

BB. *Blade of lip longer than claw.*

c. *Claw  $\frac{3}{4}$ -1 in. long.*

**nodosa**, Lindl. (*B. grandiflora*, Lindl.). Lvs. lanceolate, acuminate, channeled above: fls. few and large, corymbose; sepals and petals linear-acuminate; lip round-ovate, long-cuspidate, entire, longer than the claw. Jamaica, Mex., S. B.M. 3229, of this name, is *B. subulifolia*.

CC. *Claw very short.*

**fragrans**, Rod. Lvs. up to 16 in. long, terete, deeply furrowed above: raceme of 4-12 large fls.; sepals linear-lanceolate, yellowish white and faintly purple-spotted; petals linear, yellowish white; lip obovate, with a very short claw, a yellowish green spot at the base. Brazil. I.H. 5:180.

GEORGE V. NASH.†

**BRASSIA** (named in honor of William Brass, a botanical collector of the last century). *Orchidaceæ*. Epiphytic orchids, thriving in intermediate temperatures.

Pseudobulbs bearing 1 or 2 terminal lvs., and lateral or axillary racemes: sepals narrow, acuminate, or sometimes tailed, spreading, equal or the lateral longer; petals similar to the dorsal sepal or smaller; lip sessile on the foot of the column, spreading, flat, entire, shorter than the sepals; pollinia 2, waxy.—A genus of about 30 species extending from Mex. to Brazil and the W. Indies.

The brassias are plants of easy culture and add considerable interest to collections. They have little value as florists' flower since the colors are not suitable, but a well-grown specimen, such as is often seen in old gar-

dens, makes a most attractive object. The long-tailed sepals and petals are a characteristic of the brassias, and some have an agreeable odor. Pot culture is best, with the usual peat fiber as a rooting medium. In winter-time much less water is necessary than in the growing time, although the plants must never be dried off completely or the flowering will be interfered with. One often sees plants of *B. maculata* brought here by visitors to Jamaica, and other species are now introduced there from the mainland of South America, and thrive well. These may all be grown in an ordinary greenhouse with other plants, in fact a mixed collection, and give satisfaction. Propagation is effected by division only. Green-fly is often troublesome on the young flower-spikes and must be kept down by fumigation, or sponge dipped in soapy water. (Orpet.)

INDEX.

<i>brachiata</i> , 2.	<i>Lanceana</i> , 7.	<i>maculata</i> 3.
<i>caudata</i> , 5.	<i>Lawrenceana</i> , 6, 8.	<i>verrucosa</i> , 1.
<i>Gireoudeana</i> , 4.	<i>longissima</i> , 6.	<i>Wrayæ</i> , 3.
<i>guttata</i> , 3.		

A. *Lip with flat green warts.*

B. *Sepals 3-4 in. long: lip white.*

1. **verrucosa**, Batem. Fig. 624. Pseudobulbs ovoid, much compressed, up to 4 in. long; lvs. up to 1 ft. long: racemes 8-15-flid.; sepals and petals light yellowish green, spotted at base, the sepals 3-4 in. long, the petals about half as long; lip white, with numerous dark green warts, with a broad dilated claw, the upper part nearly orbicular, abruptly acuminate. Guatemala.

BB. *Sepals 6 in. long: lip light yellow.*

2. **brachiata**, Lindl. Pseudobulbs 3-5 in. long, oblong, compressed: lvs. up to 1 ft. long: racemes 6-12-flid.; sepals and petals light yellowish green, with a few purple basal spots, the petals about two-thirds as long

624. *Brassia verrucosa*. ( $\times \frac{3}{8}$ )

as sepals; lip light yellow, with dark green warts, constricted at the middle, the basal part nearly orbicular, the upper portions broadly triangular-ovate, acuminate. Guatemala. B.R. 33:29.

AA. *Lip without warts.*

B. *The lip with a broad claw, broadly obovate or nearly orbicular above.*

c. *Lateral sepals lanceolate, about 3 in. long.*

3. *maculata*, R. Br. Pseudobulbs 3-4 in. long, 1-lvd.: lvs. up to 9 in. long; racemes of 5-10 fls.; sepals and petals yellowish green, brown-spotted on the lower part, the sepals about 3 in. long, the petals two-thirds as long; lip cream-white, purple-dotted, with broad claw, the upper part broadly ovate, acute. Jamaica. B.M. 1691. P.M. 6:5. Var. *guttata*, Lindl. (*B. Wrayæ*, Skinner). Fls. smaller and greener. Guatemala. B.M. 4003.

cc. *Lateral sepals narrowly linear, 4-5 in. long.*

4. *Gireoudeana*, Reichb. Pseudobulbs 1-lvd., 3-4 in. long and about half as broad, much compressed: lvs. up to 1 ft. long; racemes with 6-12 fls.; sepals yellowish green, the base brown-spotted, the lateral sepals up to 5 in. long, the dorsal a little shorter; petals about half as long as dorsal sepal, the base brown, the remainder yellowish green; lip yellow, brown-spotted, with a broad claw, the upper part nearly orbicular, acute. Costa Rica.

BB. *The lip not clawed.*

c. *Lateral sepals 6-8 in. long.*

d. *Sepals greenish yellow; lip ovate.*

5. *caudata*, Lindl. Pseudobulbs up to 5 in. long: lvs. up to 10 in. long; racemes with 6-12 fls.; sepals and petals greenish yellow, brown-spotted at base; dorsal sepal about 3 in. long, the lateral 6 in.; petals about 1 in. long; lip without a claw, ovate, acuminate, light yellow with brown spots. W. Indies. B.R. 832. B.M. 3451. A.F. 6:609.

DD. *Sepals deep orange-yellow; lip oblong-lanceolate.*

6. *longissima*, Nash (*B. Lawrenceana*, Lindl., var. *longissima*, Reichb.). Pseudobulbs 2-3 in. long, compressed, 1-lvd.: lvs. up to 9 in. long; racemes of numerous fls.; sepals and petals deep orange-yellow, with a few large basal blotches; the dorsal sepal about half as long as the lateral which are 7-8 in. long and about  $\frac{1}{4}$  in. wide at base; the petals 2-3 in. long; lip oblong-lanceolate, about 3 in. long, pale yellow, acuminate, purple-spotted at base. Costa Rica. B.M. 5748.

cc. *Lateral sepals 2½-3 in. long.*

d. *Crest 2-lobed; lip oblong.*

7. *Lanceana*, Lindl. Pseudobulbs 2-lvd., 3-5 in. long, much compressed and ribbed: lvs. up to 1 ft. long; racemes of 7-12 fls.; sepals and petals light yellow, brown-spotted below, the sepals 2½-3 in. long, the petals about half as long; lip oblong, yellow, unspotted or with a few basal brown spots, undulate, acute. B.R. 1754. B.M. 3577.

625. Flower of mustard. (×2)

1-1¼ in. long. Guiana.

DD. *Crest truncate in front; lip oblong-lanceolate.*

8. *Lawrenceana*, Lindl. Pseudobulbs 2-lvd., 3-5 in. long, ribbed and much compressed: lvs. up to 1 ft. long; racemes of 7-12 fls.; sepals and petals light yellow, brown-spotted below, the sepals about 3 in. long, the petals about 1½ in. long; lip oblong-lanceolate, light yellow, about 1½ in. long, acute, undulate. Brazil. B.R. 27:18. J.H. III. 30:275.

*B. Forgetiana*, Hort. Fls. whitish with chocolate markings, the crest of the lip orange. Related to *B. maculata*. G.C. III. 48:471. —*B. Josstiana*, Reichb. f. Brazil. Gt. 3:308.

GEORGE V. NASH.

**BRÁSSICA** (old classical name). Including *Sināpis*. *Cruciferae*. Annual and biennial herbs, including cabbage and turnip, and their allies, and also the mustards.

626. Pod or silique of mustard. — *Brassica juncea*. (×1½)

Leaves various, the lower ones mostly lyrate or pinnatifid: fls. yellow, mostly in erect racemes; petals and stamens 4: pod long and slender, compressed-cylindrical or 4-sided, beaked; seeds not winged, the cotyledons conduplicate (Figs. 625, 626).—Nearly or quite 100 species in Eu., Asia, Afr., and many of them widely naturalized. The brassicas possess a remarkable natural tendency toward the thickening of parts under cult., as of root, st., axillary buds, lf.-rosettes, midribs and even of fl.-clusters. Oil is extracted from the seeds of several species, and the ground mustard of commerce is made from the seeds of *B. nigra* and others.

The brassicas are botanically much confused, particularly in the groups containing cultivated species. The manuals probably contain too few rather than too many species of Brassica; at least, the miscellaneous throwing of rutabagas, turnips, rape and other plants into *Brassica campestris* is unnatural, and, therefore, unfortunate. One of the best presentations of the true brassicas is that of De Candolle's Prodrômus, as long ago as 1824 (also in Trans. Lond. Hort. Soc., Vol. V, and in Systema, 2:582-607), and the present treatment follows that outline in general. Some of the forms that are here kept separate as species may be derived from their fellows, but the evidence of such origin is lost, and perspicuity demands that they be kept distinct in a horticultural treatise. The taxonomic arrangement here presented can be regarded as only tentative, however, and new systematic studies should be made of the entire group.

The confusion into which our brassicas have fallen is in some measure due to the various vernacular names in the different countries. The French use the word chou generically to include all forms of *B. oleracea* and the rutabaga—that is, all the blue thick-leaved brassicas; while in England the rutabaga is called the Swedish turnip. A tabular view of the different vernaculars may be useful:

French.	English.	American.
Chou cabus	Cabbage	Cabbage
Chou de Milan	Savoy cabbage	Savoy cabbage
Chou de Bruxelles	Brussels Sprouts	Brussels sprouts
Choux-verts	Borecole or Kale	Borecole or Kale
Chou-rave	Kohlrabi	Kohlrabi
	{ Swede, or Swedish turnip	} Rutabaga
Chou-nave	Turnip-rooted cabbage	
Chou-fleur	Cauliflower	} Cauliflower
Navet	Turnip.	

The Latin names in Brassica, particularly in the oleracea-campestris group, have been so variously used that it is practically impossible to place some of them accurately.

- A. Whole plant glaucous-blue when in fl.: lvs. of the fl.-sts. clasping; fls. various. (Mostly *Brassica* proper.)  
 B. Lvs. from the first more or less fleshy throughout, and glaucous-blue even when young; fls. large and creamy yellow, the petals conspicuously long-clawed, and the sepals usually erect.

1. *oleracea*, Linn. CABBAGE, CAULIFLOWER, BRUSSELS SPROUTS, KALE. Fig. 627.

627. Flowers of cabbage.—*Brassica oleracea*. ( $\times \frac{1}{2}$ )

tion, or perhaps sometimes a biennial, with a very tough and woody root, a diffuse habit, and large thick deep-lobed lvs. in various shades of green and reddish, and more or less glaucous. The lvs. of this plant were probably eaten by the barbarous or half-civilized peoples; and, when history begins, the plant had been transferred to cult. grounds and had begun to produce dense rosettes or heads of lvs. It appears to have been in general use before the Aryan migrations to the westward. There were several distinct types or races of the cabbage in cult. in Pliny's time. From the one original stock have apparently sprung all the forms of cabbages, cauliflowers, brussels sprouts and kales. For this family or group of plants the English language has no generic name. The French include them all under the term *Chou*, and the Germans treat them under *Kohl*. These various tribes may be classified as follows:

Var. *acéphala*, DC. Fig. 706. The various headless cabbages, comprising kales or borecoles, in many types and

varieties, as the tall or tree kales, curled or Scotch kales, and collards. Its likeness may be found wild on the cliffs of the south-eastern coast of England today. The thick, tender lvs. of the kales are used as "greens." See *Collards* and *Kale*. It is not certain that all the kales and collards belong here; some of them may be *B. campestris*.

628. Wild cabbage on the cliffs of the English Channel.

Var. *Caùlo-Ràpa*, DC. KOHLRABI (which see). St. tuberous above the roots, the tuber bearing the lvs.

Var. *gemmifera*, DC. The bud-bearing cabbage, or brussels sprouts (see Fig. 672). In this group, the main st. or axis is tall and erect, and axillary buds are developed into little heads. See *Brussels sprouts*.

Var. *capitata*, Linn. The head-bearing, or true cabbages, kraut of the Germans. In this group, the main axis is short and thick, and the lvs. are densely packed into a gigantic bud or head (Figs. 701-705). The varieties of cabbage are very numerous and various. See *Cabbage*. A serviceable classification of them might follow this order:

629. Flowers of rutabaga—*Brassica campestris*. ( $\times \frac{1}{2}$ )

- A. Lvs. plain (not blistered).  
 B. Head oblong or conical (Fig. 701).  
     c. Green.  
     cc. Red.  
 BB. Head oblate or flattened (Fig. 702), including c and cc, as above.  
 AA. Lvs. blistered or puckered. The Savoy cabbages, Fig. 703 (*B. oleracea* var. *bullata*, DC., or var. *sabauda*, Linn.), to be further divided, as in A.

Var. *botrytis*, Linn. Cauliflower and broccoli, in which the head is formed of the condensed and thickened fl.-cluster. Broccoli produces its heads later in the season than cauliflower, and in mild climates it is allowed to remain and make its heads in spring. See *Cauliflower*.

2. *Napus*, Linn. RAPE. Lvs. smooth from the first: differs from *B. oleracea* chiefly in habit and more deeply scalloped lvs. There are oil-producing forms (var. *oleifera*, DC.). The botanical position of the rapes is doubtful.

3. *campéstris*, Linn. First lvs. hairy; all lvs. glaucous and thickish or somewhat fleshy, the lower ones lyrate and toothed, the st.-lvs. cordate-amplexicaul and

630. Pak-choi.—*Brassica chinensis*.

acuminate; fls. shorter and also smaller than in the *B. oleracea* series (Fig. 629). A weed in waste places, in its run-wild form, but rarely persisting long or becoming troublesome. There are oil-bearing forms (var. *oleifera*, DC.).

Var. *Nàpo-Bràssica*, DC. (*B. oleracea* var. *Nàpo-Bràssica*, Linn.), is the rutabaga evolution of the plant. The rutabaga tuber is either white-fleshed or yellow-fleshed, but the preference in this country seems to be for the yellow kinds. For contrasts with turnips, see No. 4; also *Turnip* in Vol. VI.

BB. Lvs. (except upon the fl.-st.) thin and green: fls. smaller and bright yellow, less prominently clawed.

C. Plant potentially biennial (that is, the root hard and thickened, often distinctly tuberous): foliage firm in texture.

D. Foliage distinctly hairy.

4. *Râpa*, Linn. COMMON TURNIP. Lvs. prominently lyrate or interrupted below, the root tuberous.—Whatever the origin of the rutabaga and turnip may be, the two plants show good botanical characters. The tubers of the two are different in season, texture and flavor. In the rutabaga, the small lvs. immediately following the seed-lvs. are sparsely hairy, but all subsequent lvs. are entirely smooth, densely glaucous blue, thick and cabbage-like, with a fleshy petiole and midrib. In the turnip, the radical lvs. are always more or less hairy, and they are green and radish-like, thin, with slender petiole, and the lvs. are much more lyrate, with interrupted lfts. on the petiole; the small lvs. following the seed-lvs. are also thinner and narrower and more deeply scalloped. In the rutabaga, the fls. are large and creamy-yellow, whereas in the turnip

631. Tuberous root of pak-choi.—*Brassica chinensis*.

they are small, yellow and mustard-like, with shorter claws and more spreading calyx. The turnips vary in hairiness, but the cone of expanding lvs., or the "heart-lvs.," always shows the hairs distinctly, while the heart-lvs. of the rutabagas are normally entirely glabrous, fleshy, and remind one of the young shoots of sea-kale. The turnip usually produces seed freely if the bottoms are left in the ground over winter; and thereby the plant spreads, becoming a true annual and a bad weed, with a slender hard root. Oil-producing forms are var. *oleifera*, DC.

DD. Foliage not hairy.

5. *chinensis*, Linn. PAK-CHOI CABBAGE. Fig. 630. Radical lvs. broad and ample, glossy green, obovate or round-obovate in general outline, either entire or obscurely wavy or even crenate, tapering to a distinct and thick strong petiole, which is usually not prominently margined: pod large and tapering into a beak half an inch long: root sometimes tuberous (Fig. 631).—This plant is grown by the American Chinese, and is occasionally seen in other gardens (see Bailey, Bull. No. 67, Cornell Exp. Sta.). It is impossible to determine whether this particular plant is the one that Linnaeus meant to distinguish by his *Brassica chinensis*, but it best answers the description in his *Amœnitates* (Vol. IV). In Linnaeus' herbarium is a *Brassica* marked "chinensis" in his own handwriting, but it shows purple fls. and has lyrate-lobed lvs., whereas Linnaeus described his plant as having yellow fls. and cynoglossum-like lvs.; probably not the original.

6. *napiformis*, Bailey (*Sinapis juncea* var. *napiformis*, Paill. & Bois). TUBEROUS-ROOTED CHINESE

MUSTARD. Fig. 632. Radical lvs. comparatively few, the blade thin and oval in outline, and on long and slender, slightly feathered petioles, sharply and irregularly toothed, with a thin bloom: beak of the pod more abrupt: root distinctly hard and tuberous.

China.—This vegetable appeared in France in 1882 from seeds sent by Bretschneider, of the Russian legation, Pekin. It was offered by American seedsmen as early as 1889. The plant is a biennial, with thin bluish foliage, and a small tuberous root like a conical turnip. These roots reach a diam. of 3 or 4 in., and are scarcely distinguishable from white turnips in appearance, texture and flavor. In China the tubers are used as a winter vegetable, the seeds being sown in summer. The plant does not appear to have been brought to the attention of botanists until Bretschneider published

632. Lower stem leaf of *Brassica napiformis*.

an account of it in a French journal in 1881. Paillieux and Bois (Le Potager d'un Curieux) regard it as a variety of *Brassica juncea*, to which the Chinese mustard belongs, but it is very different from that plant. It is nearly related to pak-choi, and it may have sprung from the same species; but it is clearly distinguished by its sharply toothed lvs., one of which is shown in Fig. 632.

CC. Plant truly annual: foliage profuse, loose and soft.

7. *Pe-tsai*, Bailey PE-TSAI CABBAGE. Fig. 633. Numerous radical lvs., large and light green, oblong or ovate-oblong, crinkled and very veiny, and the margins

wavy, contracted into a flat and ribbed petiole 1-3 in. wide, which is provided with a wide thin notched or wavy wing; st.-lvs. sessile and clasping: pod of medium size, with a short cone-like beak.—The pe-tsai, or Chinese cabbage, is no longer a novelty in American gardens, although it does not appear to be well known, and its merits are not understood. Its cult. and peculi-

633. *Brassica Pe-tsai*.

arities were described in France as long ago as 1840, by Pepin, who says that, while the plant had been known in botanic gardens for 20 years, it was brought to notice as a culinary vegetable only 3 years before he wrote. It appears to have attracted little attention in Eu. until late in the last century, however. It began to attract attention in the U. S. probably about 25 years

ago. The lvs. tend to form an oblong loose head, like cos lettuce. *Cabbage*; also page 3582.

AA. *Whole plant green or but slightly glaucous when in fl.: lvs. on the fl.-sts. not prominently clasping: fls. small and yellow. Annuals. (Sinapis or Mustard.)*

B. Pod long, terete or nearly so: pedicels spreading.

8. *japonica*, Sieb. POT-HERB MUSTARD. Fig. 634. Annual, self-sowing: rather numerous radical lvs., oblong or oblong-obovate, the margins either crisped or cut into many very fine divisions, the petiole distinct at its lower end; st.-lvs. all petioled: pod very small, with a slender beak. —The very soft thin lvs. make excellent "greens." Long known, but with no designative name, in old gardens in this country, and sometimes run wild about premises. Intro. in 1890 by John Lewis Childs as California pepper-grass. A very worthy plant (Bull. 67, Cornell Exp. Sta.).

634. *Brassica japonica*, the radical leaves used for greens.

9. *junceae*, Coss. (*Sinapis juncea*, Linn.). CHINESE MUSTARD. Figs. 626, 635. Rank and coarse grower, in the common forms making great tufts of root-lvs. if sown early: radical lvs. usually abundant and often very large, oval or obovate in outline, the blade angled or toothed, tapering into a narrow petiole, which generally bears leafy appendages; lower st.-lvs. more or less toothed and petiolate, the upper ones oblong or oblong-lanceolate, entire and usually sessile or alternate: flowering sts. and lvs. more or less lightly glaucous: fls. bright yellow: pod slender, of medium size, tapering into a short seedless beak. Asia.—This species is held by Hooker and Thomson (Journ. Linn. Soc. v. 170) to include a great variety of forms, as *Sinapis levigata*, Linn.; *S. integrifolia*, Willd.; *S. ramosa*, *S. rugosa*, *S. patens*, *S. cuneifolia*, Roxbg.; *S. lanceolata*, DC., and others. There are two types of it in cult. in our gardens, one with the radical lvs. somewhat sharply toothed and nearly smooth below (sometimes grown as

635. Broad-leaved Chinese mustard.—Form of *Brassica juncea*.

*Brassica* [or *Sinapis*] *rugosa*), the other with root-lvs obtusely toothed and spinescent on the veins below (comprising Chinese mustard, Chinese broad-leaved mustard, and brown mustard). Linnæus founded his *Sinapis juncea* on a figure in Hermann's *Paradisus* (Hermann, *Paradisus Batavus*, t. 230, 1705), which represents a plant very like the former type mentioned above, and which Hermann described as "lettuce-leaved."

10. *alba*, Boiss. WILD MUSTARD. Tall: lvs. pinnatifid and rough-hairy: pods spreading, hairy, the lower part thick and few-seeded, the beak longer: seeds pale brown, large. Weed, from Eu.

11. *arvensis*, Kuntze (*B. Sinapistrum*, Boiss. *Sinapis arvensis*, Linn. *Sinapistrum arvense*, Spach). CHARLOCK. Tall: lvs. strong-toothed, or sometimes nearly lyrate: pods knotty, glabrous or hairy, the upper third indehiscent and 2-edged, usually 1-seeded. Weed, from Eu.

BB. Pod short, distinctly 4-angled: pedicels and pods appressed.

12. *nigra*, Koch. BLACK MUSTARD. Fig. 636. St. tall and upright, with wide-spreading branches: lvs. pinnatifid, somewhat hairy: pods short and erect, glabrous; seeds small and dark brown, pungent, supplying the mustard of commerce. Cult. in Eu., but a weed in this country.—Commercial mustard is the flour of the seeds of this species chiefly, but the seeds of *B. alba* and probably of *B. juncea* are sometimes used.

*B. adpressa*, Boiss. Annual or biennial, much like *B. nigra* but st. stiffer, lvs. less divided and plant somewhat hoary: pods with a short 1-seeded beak. Occasionally adventive from Eu.—*B. sinensis*, Hort. = *B. chinensis*.

Many forms of *Brassica* have been described that it is not necessary to endeavor to account for here. Studies in crossing may be expected to indicate some of the relationships. The writer has found no difficulty in crossing cabbage-kale-cauliflower and others. See Lund and Kjaerskou, *Landbrügets Kulturplanter* No. 4; and 'Morfologisk-anatomisk beskrivelse af *Brassica oleracea*, *B. campestris* og *B. Napus*.'

L. H. B.

**BRASSOCATTLÆLIA** (compounded from *Brassavola*, *Cattleya* and *Lælia*). *Orchidaceæ*. A small group of trigenic hybrids between the genera *Brassavola*, *Cattleya* and *Lælia*.

*B. balarucensis* (*B. Digbyana* × *L.-C. Schilleriana*).—*B. Fuerstenbergii* (*Brassolælia Gratrixia* × *C. Trianae*).—*B. Máckayi* (*B. Digbyana* × *L.-C. elegans*). See also *Adamara* and *Linneara*.

**BRÁSSOCÁTTLEYA** (compounded from *Brassavola* and *Cattleya*). *Orchidaceæ*. A genus established to include hybrids of the species of the genera *Brassavola* and *Cattleya*.

The following, among others, are offered in the American trade:

*B. Akèbenii* (*B. Digbyana-gigas* × *C. Luddemaneana*).—*B. Alexánderi* (*B. Digbyana* × *C. citrina*).—*B. Chámberlainiæ* (*B. Digbyana* × *C. quadricolor*).—*B. Cliftonii*, Hort. (*B.-C. Digbyana-Massia* × *C. Trianae* var. *Uplands*). G.C. III. 45:34. O.R. 18:48.—var. *Wellesleyæ*, Hort. G.C. III. 51:135.—*B. conspicua* (*B. glauca* × *C. Leopoldii*).—*B. Digbyano-Förbesii* (*B. Digbyana* × *C. Forbesii*).—*B. Digbyano-gigas* (*B. Digbyana* × *C. Gigas*).—*B. Eva* (*C. Lawrenceana* × *B. Digbyana*).—*B. gesneriæflóra* (*B. fragrans* × *C. maxima*).—*B. heatonensis* (*B. Digbyana* × *C. Hardyana*).—*B. Hólfordii* (*C. Forbesii* × *B. Digbyana*).—*B. Hyæz* (*B.*

636. Siliques of *Brassica nigra*. (×1)

Digbyana × C. Harrisoniana).—*B. langleyensis* (B. Digbyana × C. Schroederæ).—*B. Laurentiano-glauca* (B. Laurentiano × C. glauca).—*B. Leemannii* (B. Digbyana × C. Dowiana). O.R. 11:57.—*B. Mariæ* (B. Digbyana × C. Warneri).—*B. Maronæ* (B. Digbyana × C. Warszewiczii).—*B. nivâlis* (B. fragrans × C. intermedia).—*B. Peetersii* (B. glauca × C. Lawrenceana).—*B. Pocahontas* (B. Digbyana × C. Eldorado).—*B. Sânderi* (B. glauca × C. Schroederæ).—*B. sandhaghensis* (B. Digbyana × C. Setulleriana).—*B. striata* (B. fragrans × C. Mossiæ). Fls. rose-colored, fragrant. R.H. 1903:276, desc.—*B. Süssanæ*. (B. Digbyana × C. Thayeriana).—*B. Thônionii* (B. Digbyana × C. Gaskelliana). J.H. III. 61:601.—*B. Veitchii* (B. Digbyana × C. Mossiæ).—*B. Vilmoriniana* (B. Leemannii × C. Mossiæ).—*B. Wellesleyæ* (B. glauca × C. Mossiæ Wageri).

*Brassavola Digbyana*, Lindl., is now considered a *Lælia*, so the above hybrids, under that conception, might be designated *Lælio-Cattleya*.

GEORGE V. NASH.

**BRÁSSO-LÆLIA** (compounded of the genera *Brassavola* and *Lælia*). *Orchidaceæ*. Established to include hybrids between the two genera.

The following are to be found in the American trade:

*B. Canari* (B. Digbyana × L. xanthina).—*B. Digbyano-purpurata* (B. Digbyana × L. purpurata).—*B. fladôsa* (B. nodosa × L. flava).—*B. Helen* (B. Digbyana × L. tenebrosa). O.R. 10:169.—*B. Jéssopii* (B. Digbyana × L.-C. xanthina).—*B. Lellieixii* (B. Digbyana × L. anceps).—*B. Rölfei* (B. Digbyana × L. crispa).—*B. Thwaitesii* (B. Digbyana × L. grandiflora).—*B. Veitchii* (B. Digbyana × L. purpurata).—*B. westfieldensis* (B. glauca × L. flava).

*Brassavola Digbyana*, Lindl., is now considered a *Lælia*, so the above hybrids, under that disposition, might be designated as hybrid *Lælias*.

GEORGE V. NASH.

**BRÁSSO-LÆLIA-CATTLEYA**. *Orchidaceæ*. A trigenic hybrid. *B.-L.-C. Fowléri* (C. Schroederæ aurantiaca × Brasso-Lælia Mrs. M. Gratrix). Fls. yellow, tinged, and veined with salmon-rose. G.C. III. 41:303. *Brassavola Digbyana*, one of the elements, is now considered a *Lælia*, and the plant would then belong to *Lælio-Cattleya*.

GEORGE V. NASH.

**BRAVÔA** (Bravo, Mexican botanist). *Amaryllidaceæ*. A small genus, much resembling in some of its species the tuberose (*Polianthes*), and hardly distinct from it.

Stems slender, from small thickened rootstocks: lvs. mostly basal: infl. a lax spike or raceme; fls. always in pairs, more or less bent or curved; stamens 6, included within the perianth-tube: fr. 3-celled, many-seeded. Native of the mountain and tableland region of Mex.—Five species have been described formerly, but recent explorations have discovered some 5 or 6 additional species.

While the flowers are not so showy as the common tuberose, yet the genus should be found in every choice bulb collection. Only one species has been cultivated to any extent, and even this species is not well known. As the species often grow in the high mountains of Mexico, they ought to be hardy in the southern stretches of the temperate zone.

**geminiflora**, Llav. & Lex. MEXICAN TWIN-FLOWER. Sts. 1-2 ft. high: bulbs small, 1-1½ in. long, the outer scales cut into fine fibers at the top: basal lvs. linear, erect, 6 lines or less broad, smooth: fls. in a slender raceme, reddish or orange-colored; lobes minute, rounded. B.M. 4741.—Handsome, and worthy of more attention.

*B. Bulliana*, Baker. Basal lvs. described as lanceolate, 1-1½ in. broad: fls. in 5 or 6 pairs, white. Seemingly too near the little-known

*Polianthes mexicana*. Not in cult.—*B. sessiliflora*, *B. densiflora*, and *B. singuliflora*, are rare species, only known from herbarium specimens. The latter two, however, should probably be excluded from this group.

J. N. ROSE.

**BRÀYA** (Count de Bray, 1765-1831, German botanist). *Cruciferae*. Small tufted alpine or boreal perennial herbs, sometimes grown in alpine gardening. There are a dozen or more species in Eu., Asia and Amer. Plant glabrous or cano-tomentose: lvs. radical, spatulate or linear, entire or dentate: fls. on scapes that often are naked and sometimes only 1-fl'd. but mostly bearing racemes or corymbs, white or rose-colored or purple. *B. alpina*, Sternb. & Hoppe, is the usual species, with white fls. *B. pinnatifida*, Koch (probably properly *Sisymbrium pinnatifidum*, DC.), has white-lilac fls. Practically unknown in cult. in N. Amer.

**BRAZIL-NUT:** *Bertholletia*.

**BREAD-FRUIT:** *Artocarpus*.

**BREAD-NUT:** *Brosimum Alicastrum*.

**BREEDING OF PLANTS.** The definite producing of kinds of plants adapted to given uses and conditions is known now as plant-breeding. The existing varieties are of course the result of the action of natural tendencies and laws, but the producing of them has not been, for the most part, a conscious, or at least not a regulated, act on the part of man. The laws of variation and inheritance are now beginning to be understood, and the application of this knowledge is to produce orderly and more or less predictable results.

In beginning the artificial cultivation of plants, our early ancestors, even with their crude understanding and methods, probably selected seed for planting from the best wild individuals of any plant. The selection of seed from the best individuals has thus been continuing for thousands of years, ever since the dawn of civilization. While this is a crude method of breeding, if long continued on an extensive scale, it could not, as is now recognized, fail to have results. The greatness of the changes produced is shown by the fact that some of the most extensively cultivated crops, such as wheat and maize, have been so modified that the wild types from which they sprang cannot now be recognized, although the original wild ancestors probably still exist.

Breeding did not become established as an art until comparatively recently. The sexuality of plants was not established until it was proved experimentally by Camerarius in 1691; and the first hybrid of which there is record was made in 1719 by Thomas Fairchild, an English gardener, who crossed the carnation with the sweet william. The first exact knowledge of hybridization dates from about 1761 when Koelreuter began publishing the results of his observations, but even his work had little bearing on practical plant-breeding. The systematic breeding of plants may be said to have begun with the work of Knight and Von Mons about the beginning of the nineteenth century.

Knight worked mainly in hybridization and in 1806 said: "New varieties of every species of fruit will generally be better produced by introducing the farina of one variety of pollen into the blossoms of another than by propagating from a single bud." Von Mons worked mainly in selection and it is interesting to note that his experiments were made primarily with pears. He emphasized continuous selection and produced very many valuable varieties. It is probable that a large part of the success of Von Mons' work was due to the fact that pears are normally sterile to their own pollen, requiring cross-fertilization, and, therefore, many of his new varieties were probably hybrids. He was not aware of this fact, however, and it made no great difference in the establishment of the principle which has since proved to be so important.

A most important stimulus to the development of

plant-breeding was given by the publication of Darwin's famous works, particularly his "Animals and Plants under Domestication," in 1868. His extensive researches, masterful compilation and systematization of the existing knowledge may be said to have established breeding on a systematic basis.

Following Darwin, little advance was made in the knowledge of the principles of breeding until in 1900, when Mendel's papers on plant hybridization, describing his now famous principles or laws of inheritance, were rediscovered independently and brought to attention by DeVries, Correns and Tschermak. The discovery of these laws and the publication of DeVries' "Mutation Theory" in the same year, marked the beginning of a new era in plant-breeding. No matter what the final conclusions may be regarding Mendel's principles and the mutation theory, the stimulation which these two theories have given to breeding has already served greatly to modify and extend knowledge, both in scientific and practical directions.

The great advance that has been made in the discovery of the underlying principles of breeding puts experimentation in this field on a much surer basis and the breeder can now approach his subject with definite understanding.

637. Variations in size of wheat plants grown side by side in field.

#### Classification of varieties.

To understand clearly the character of organisms with which breeding deals, careful definitions of the different groups of cultivated plants which are ordinarily known as varieties are needed. One speaks of varieties of wheat, corn, apples and pears, yet it is known that these varieties differ from each other as natural groups. In order to distinguish clearly these differences, the following classification of varieties into races, strains and clons has been proposed:

**Races** are groups of cultivated plants that have well-marked differentiating characters, and propagate true to seed except for simple fluctuating variations. The different groups of beans, peas, wheat, oats, corn, cotton, and the like, referred to commonly as varieties, are thus in a more restricted sense races. Boone County White, Leaming, Golden Bantam, and so on, would be recognized as races of corn, and Turkey Red, Fulcaster, Fultz, as races of wheat, and Early Paris, Dwarf Erfurt and Snowball as races of cauliflower.

**Strains** are groups of cultivated plants derived from a race, which do not differ from the original of the race in visible taxonomic characters. When the breeder, by a careful selection of Blue Stem wheat, produces a sort of Blue Stem that differs from the original race only in the quality of yielding heavily, it would be called a strain of Blue Stem.

**Clons** are groups of cultivated plants the different individuals of which are simply transplanted parts of the same individual, the reproduction being by the use of vegetative parts such as bulbs, tubers, buds, grafts, cuttings, runners, and the like. The various sorts of apples, potatoes, strawberries, chrysanthemums, and so on, commonly denominated varieties, in a more restricted sense would be clons. Clons of apples, pears, strawberries, potatoes, and the like, do not propagate true to seed, while this is one of the most important characters of races and strains of wheat, corn, and others. The term variety would thus be used in a general sense, and would include races, strains and clons.

#### Heredity.

The laws of heredity are of primary importance to the breeder. It is a general principle that like begets like, but it is also true that like frequently gives rise to

unlike. In general, by heredity is meant the tendency which an organism manifests to develop in the form and likeness of its progenitors, and the study of heredity includes thus the inheritance of characters. It is of the utmost importance that organisms in general reproduce their kind, as otherwise the breeder would be confronted with confusion, but it is of equal importance that the offspring does not always reproduce the parental characters. There are thus apparently two conflicting principles in plant-breeding. On the one hand, the breeder seeks to produce variations in order to get new types as the foundations for improvement. On the other hand, when such a variation from or improvement on the normal type is secured, he reverses the process and tries to establish heredity and reduce the amount of variation, so that the aphorism, "like begets like," will hold true.

In pedigree- or grade-breeding, and in breeding to produce new varieties, the importance of hereditary strength cannot be overestimated, as it is only by rendering this power very great that any new form can be brought to what is called a fixed type.

In recent years, the ideas of fixity of type have been greatly modified, and it is now held that fixity of type is secured by purifying a race from all admixtures so that any character represented in a race will be pure.

#### Unit-characters.

The modern studies of heredity have led to a new conception of organic characters that should be clearly understood by the breeder. A careful study of species or varieties of plants or animals focuses the attention not on the generality of the differences existing but rather on the differences in certain characters; one observes whether a plant is smooth or hairy, cut-leaved or entire-leaved, much branched or simply branched, erect or procumbent, tall or short, and the like. This leads to the conception that a plant is not of simple organization but is comprised of a combination of characters. These characters or the physiological units which cause them are now thought of as in considerable measure independent of each other and as representing distinct organic units. The classical studies of Grego

638. Red cedar: a, Columnar form; b, Spreading form.

Mendel on the hybridization of races of peas that exhibited different characters established the fact that at least certain characters are inherited separately and may form permanent new combinations.

A unit-character, then, may be defined as any characteristic quality or set of qualities or expression of character in an organism that is inherited as a whole and independent of any other quality or set of qualities. They are the organic units of inheritance. The units that are considered in hybridization are not the species or varieties themselves, but the unit-characters of which they are composed. The origin of a new

variety would then consist in the acquirement of a new character by the organism or the loss of an old character or of the production through hybridization of new combinations of characters that already existed but in different combinations.

#### Nature of variation.

While, as indicated in the discussion of heredity, organisms are usually reproduced in the likeness of their parents, nevertheless it is well known that all plants vary. Individual plants differ from one another just as do men. The fact that plants can be improved by selection depends upon the occurrence of these so-called variations. One is accustomed to think of plants as very stable and uniform. Casually looking over a field of ox-eye daisies and admiring their beauty, one distinguishes no apparent variability; all seem to be alike. Nevertheless, if the plants are examined carefully and the different individuals studied, it is found that each one possesses certain peculiarities. Some have large flower-heads, others small flower-heads; some have very many rays or petals, others comparatively few; some have broad rays, others narrow rays. Some plants are tall, others short. No two plants can be found which do not differ from each other in some noticeable character. They present different facial expressions, the same as do people or cattle, so that different individuals may be recognized after one has studied them and made their acquaintance. This is one of the interesting studies which the breeder pursues. Careful gardeners learn to recognize the individual plants that they handle day after day as the shepherd recognizes the different members of his flock.

The inheritance of a character ordinarily does not mean its exact expression in the offspring as in the parent. In considering variations from the standpoint of the conception of unit-characters, it must be remembered that only the determiners of a character are inherited and the expression of the character in the new individual is influenced by the environment under which the individual develops. It must also be remembered that in the higher plants and animals with which the breeder ordinarily has to deal, an individual results from a fertilized egg-cell which contains the heritage determiners of two parents and, as there are a very large number of characters making up any individual and as different individuals possess different determiners which are brought together in fertilization, rarely or never can one individual be conceived to be an exact counterpart of another.

*Variations* are of very great difference in magnitude and kind; and while many different names have been given to the different types of variation, the most generally accepted usage at present is to classify all variations either as fluctuations or mutations.

*Fluctuations* are those variations that are supposed to be due to the direct action of environment and that are not inherited. The variation in size as a result of richness of soil, is such a fluctuating variation and, as well recognized, is not a heritable character. A similar illustration of such a variation is the difference in size of oat or wheat plants due to crowding in the field (Fig. 637). It is known that if a pole bean be transferred to the North, it tends to produce a bush type, and if a cowpea be transferred to the North, it tends to shorten up its vine and assume a bush habit. An interesting illustration of such modifications is shown in the ordinary red cedar, *Juniperus virginiana* (Fig. 638). In the rich, moist soils of Pennsylvania, Maryland and Virginia, this tree forms a beautiful tall columnar top with dense foliage (Fig. 638 *a*). On the dry, sterile, limestone hills of Kansas, Nebraska, and Kentucky, and in the sandy soil of Florida, the same tree produces a spreading, scraggly top of entirely different character (Fig. 638 *b*). If one of these trees is trans-

planted while young, from sterile barren soil to moist rich land, it assumes the tall columnar habit as a result of the environment.

Plant-breeders have sometimes assumed that such modifications, which are the result of environment (Fig. 639), are of great importance to them. This matter, however, is in grave doubt. The information at command indicates that these characters, which are physiological adaptations, are not hereditary, and are lost as soon as the plant is transferred again to its normal environment. If, for example, it is desired to produce a bush cowpea and the selection is undertaken in the South with a viny variety, a search should be made among the plants for the individual that approaches most nearly to the bush type, and it is probable that this plant would be as likely to transmit this character to its progeny as a similar bushy type selected under northern conditions. As a matter of fact, it may be that this tendency could be recognized much more

639. Variation in size of dandelion caused by growing at different altitudes. *a*, Plant grown in valley at low altitude; *b*, plant grown on mountain at high altitude. (From Bonnier.)

clearly in a southern location, where the plants normally produce vines, than in a northern location.

*Mutations*, on the other hand, are changes that are more profound and effect the germinal cells of the organism in such a way that the changes are inherited. The most typical illustrations of mutations are the striking large type-variations that are known to gardeners as sports, and which ordinarily reproduce true to seed. It must not be understood, however, that all mutations are large type-variations. This, it is true, was in large measure the meaning given to mutations by DeVries in his development of the mutation theory of evolution, but the more general interpretation of biologists at present is to consider any type of variation that is inherited as a mutation. Many small variations, such as a slight difference in height of ear in corn, may be regularly inherited, and in some instances differences that are so slight as to be distinguished only by careful biometrical analysis are regularly inherited, generation after generation, even under very different conditions. Recent scientific studies have emphasized

the great importance of such variations in the production of cultivated varieties and the evolution of species. As is well known to gardeners, these sports or mutations appear suddenly without warning or reason, so far as is known. They cannot be produced, and one must simply wait until they appear and then be prepared to recognize and propagate them. Mutations usually reproduce their characters without much reversion to the parental type except such as is caused by cross-pollination. Mutations of self-fertilized plants thus usually come true to type, while in cross-fertilized plants the mutation must usually be cultivated in an isolated place and carefully selected to weed out the effect of such crossing as has occurred. Many seedsmen examine their trial-grounds regularly for sports or mutations, and many of the best varieties have resulted from the selection of such sports. Livingston, of Ohio, who during his life was famous for the number of new varieties of tomatoes which he produced, made it a practice to search regularly the fields of tomatoes, which he grew for seed purposes, for such sports, and almost all of his numerous varieties were produced by the discovery of such striking variations.

A very interesting case of a variety that originated as a seedling sport or mutation is the now familiar case of the Cupid sweet pea. Until about fifteen years ago the only sweet peas known were the ordinary tall twining sorts which grow to a height of 3 to 6 feet, depending upon the richness of the soil. At this time there was found in California, a small dwarf sweet pea plant only about 6 or 8 inches high. This was growing in a row of the Emily Henderson variety, one of the ordinary tall sorts from which it evidently had sprung. Seed of this

different sorts, until now there are varieties of Cupids representing almost all variations of color and shape of flower known in the sweet pea family.

#### *Causes of variation.*

Understanding of the causes of variation is as yet very imperfect. Fluctuations are in general interpreted as the direct physiological action of environment on the plant, or, in other words, environmental reactions. There would seem to be no doubt of the correctness of this view for the cause of ordinary fluctuations, and it may be accepted as the cause of such fluctuating variations as the breeder will commonly meet. Such reactions as the changes in structure and form of the entire air-leaves and finely divided water-leaves of certain buttercups (*Ranunculus*) and the floating and submerged leaves of pondweeds or *Potamogeton* (Fig. 640), and the loss of knees on the bald cypress when cultivated on high land where the soil is well aerated, may be interpreted merely as extreme environmental reactions. Even these extreme changes are not inherited other than that the ability to react in this way under different environments is inherited.

To account for mutations is, however, a much more difficult matter and no definite conclusion as to their cause has yet been reached. Lamarck and his followers have strongly maintained the hypothesis that changed environment would stimulate the production of variations that would permanently effect the organism and its progeny in the direction of better adapting them to their environment. Many scientists, even today, believe in the effectiveness of environment in developing adaptive changes. Weisman and his followers, however, appear to have shown that characters acquired through external influences, the so-called acquired characters, do not affect the germ-cells, which are early differentiated in the development of the organism, and are thus not inherited.

While, in general, it is certain that the ordinary environmental reactions are not inherited, it is known that plants long grown under a certain environment become modified to suit that environment, and that such adaptive changes have in some way so modified the organism that the adaptive changes are rendered heritable. Thus the conclusion follows that in some way environment by its stimulation does occasionally affect the germ-cells and produce changes that are inherited. Plants that have long been cultivated under widely varying conditions almost invariably develop numerous heritable variations that would be classed as mutations. The older breeders strongly held to the belief that such conditions as change of food-supply, change of altitude, artificial cultivation, budding, and grafting, indeed the ordinary manipulation of agricultural cultivation, lead plants to vary in directions of importance to the breeder. Clearly, no problem is of more importance to the breeder than to be able to produce or cause such new characters to appear.

It is only very recently that the idea has developed that one can go farther than possibly to change the environment. With the publication of MacDougal's researches in 1906, describing mutations that were apparently caused by injecting the capsules of plants with certain solutions, such as zinc sulfate and magnesium chloride, a possible new method of forcing variations was introduced. MacDougal apparently obtained marked variations as a result of his treatment, that were inherited in succeeding generations.

Tower, by subjecting potato beetles during the formation of the germ-cells to extremely hot and dry or hot and humid conditions with changes of atmospheric pressure, was able to cause the development of marked changes or mutations that were found to transmit their characters true through several generations and which segregated as unit-characters following hybridization. He concludes from his experiments "that heritable variations are produced as the direct response to external stimuli."

Gager has produced similar changes in plants by subjecting the developing ovaries to the action of radium rays, and a number of similar studies by Hertwig and others indicate that radium emanations have a very active effect on both plants and animals.

While the evidence favoring the value of such external stimuli as the above in producing new heritable characters is apparently definite and positive, the extent to which the method can be used in

dwarf plant was saved and grown, and it was found to reproduce plants of the same dwarf character. The variety was designated the Cupid, under which name it was introduced to the seed trade and distributed over the world. The Cupid differed from other sweet peas not only in height but in its closely set leaves and general habit of growth. Indeed it is as distinct from other sweet peas as are distinct species of plants in nature. From the original Cupid, there have sprung many

practical breeding has not been determined, and indeed further experience must be awaited before the evidence, or the interpretation of the evidence presented in these very valuable and suggestive researches, can finally be accepted. Humbert has made experiments in which the capsules of a pure line of a wild plant (*Silene noctiflora*) were injected with the solutions used by MacDougal, and although the number of plants handled (about 15,000) was apparently as great or greater than was used in MacDougal's experiments, no mutations were found in the treated plants that were not also found in the untreated or check plants.

Some observations and experiments are recorded in literature which indicate that mutilations or severe injury may induce the development of mutations. Most noteworthy among such observations are those of Blaringhem, who by mutilating corn plants in various ways, such as splitting or twisting the stalks, apparently produced variations that bred true without regression and which he described as mutations. Observations on the great frequency of striking bud-variations on recovering trunks of old citrus trees in Florida, following the severe freeze of 1894-5, also furnished evidence in support of this theory.

While the evidence at command regarding the artificial production of mutations is not yet sufficiently exact and trustworthy to enable one to draw definite conclusions and formulate recommendations for practical breeders, it may be stated that this is apparently one of the most profitable lines of experimentation for the immediate future.

### Principles of selection.

Selection is the principal factor of breeding, both in the improvement of races and in the production of new races and varieties (Fig. 641). The keynote of selection is the choice of the best, and a factor of the highest importance in finding the best is the examination of very large numbers.

In evolutionary studies, it has long been recognized that variation is the foundation of evolution and that no evolution is possible without variation; but, to selection has been assigned an all-important part as guiding and even stimulating the variation in a certain direction. Darwin, and particularly some of his more radical followers, have assigned to selection a creative force, in that it has been assumed that when nature by a slight variation gave the hint of a possible change in a certain direction, natural or artificial selection, by choosing this variation and selecting from among its progeny the most markedly similar variants, could force the advance in the direction indicated. Since Darwin's time, this cumulative action of selection had been emphasized so forcibly that selection had come to be recognized as an active force in creation rather than merely as a determinative agency.

It is certain, of course, that, by careful observation and selection from any particular race, ultimately a new race may be produced. The question is whether the individual or individuals selected in producing the new race have not varied by mutation or seed-sporting rather than being merely representative of the cumulative result of the selection of slight individual variations. The sugar-beet furnishes an interesting illustration in this direction. It will be remembered that Louis Vilmorin started the selection of sugar-beets for richness in sugar between 1830 and 1840, selecting first by means of specific gravity, the method being to throw the beets into solutions of brine strong enough so that the great majority of them would float, the few that sank being of greater specific gravity and presumably of greater sugar-content. Considerable improvement was produced by this method. About 1851, the method of chemical analysis was introduced to determine the exact sugar-content. At this time, the sugar-content was found to vary from 7 to 14 per cent, and in the second generation of selection individuals with 21 per cent of sugar were found. The selection based on percentage of sugar, using the beets highest in sugar as mothers, has been continued regularly since that time, and the industry has come to rely entirely on careful selection for high sugar-content. It would be expected that under these conditions, the percentage of sugar would have increased sufficiently so that the selected plants could be considered a different race or strain. Yet, after fifty years of selection, the highest sugar-content found is only about 26 per cent, and this in a very few

instances, seldom over 21 per cent being found. At the present time, many thousand analyses are made every year, so that abundant opportunity is afforded to find individuals producing a high sugar-content. On the contrary, when Vilmorin's work was started, the determination of sugar-content was made by very laborious methods, and was limited to comparatively few individuals. It is not improbable that if Vilmorin had been able to make analyses of the sugar-content in many thousands of roots, he would have found certain individuals producing as high as 26 per cent. The inference from this illustration would be that the limitations of the variation within the race have not been surpassed as a result of selection.

641. Improvement of corn by selection. Boone County White corn on left, and original type from which it was developed by selection on right.

Of recent studies favoring the active influence of selection in creating or strengthening characters, the most noteworthy are those of Castle and Smith.

Castle and his assistants made an extensive series of experiments with hooded rats to increase the black-colored dorsal band on the one hand and to decrease or obliterate it, on the other. He appears to have obtained very positive evidence favoring the gradual cumulative action of the selection, as he succeeded in markedly increasing the amount of black in one strain until the rats were almost wholly black and in the other strain almost wholly obliterating the black. Castle has also obtained similar results in producing a four-toed race, and a change of coloring in guinea-pigs. His view may be summarized in the following quotation: "In Johannsen's view, selection can do nothing but sort out variations already existing in a race. I prefer to think with Darwin that selection can do more than this; that it can heap up quantitative variations until they reach a sum total otherwise unattainable, and that it thus becomes creative."

The experiments conducted by Smith and others at the Illinois Experiment Station on selecting high and low strains of corn with reference to oil- and protein-content, have resulted in markedly distinct strains possessing these qualities. Experiments have also been made in cultivating these varieties without selection and the new characters have been maintained for several years without marked regression.

The standard researches of DeVries, now familiar to all, challenged the correctness of the selection theory and sought to show that species originated by sudden jumps or mutations. It may be admitted that DeVries proved that species or new characters were formed suddenly as mutations, but this would not prove that they might not also be formed or actually induced to mutate by a continuous process of selection. Indeed, in his experiments on the production of a double-flowered variety of *Chrysanthemum segetum* ("Mutationstheorie," Vol. I, p. 523), a few generations of selection led to increasing markedly the number of ray-florets before the ligulate corollas appeared among the disk-florets, the change that he interpreted as the mutation that gave him the double variety.

Tower's experiments with the potato beetle in attempting to create by selection large and small races, albinic and melanic races, and races with changed color-pattern, although conducted carefully from ten to twelve generations, failed to give any evidence of producing permanently changed types. While strains of plus and minus varieties gave populations with a range of variation apparently markedly restricted to their respective sides of the normal variation range, still these selected strains did not greatly exceed the normal range of variation in either direction, and when the selection was discontinued, in two or three generations, again populations exhibiting the normal range of variation were produced. Jennings, in a series of selection experiments with *paramecium* extending over twenty generations, and Pearl, in an extensive experiment in the selection of chickens in an attempt to produce a breed of high egg-laying capacity, failed to secure any evidence favoring an accumulative effect of selection.

No series of experiments have had a more profound influence on the conception of selection than those of Johannsen, the Danish investigator. In studying commercial varieties of beans, he found that such characters as weight and size of seed fluctuated around a certain average, and when large seed or small seed was chosen, the progeny showed the influence of the selection, being smaller or larger in accordance with the direction of the selection. The progeny, however, did not exhibit the extreme sizes of the selected parents, there being a certain regression toward mediocrity. In investigating this matter, Johannsen was led to use the ordinary pedigree method of cultivating the progeny of different individuals separately and inbreeding or selfing all seed used to prevent the

crossing of different strains. By this method, he found that the progeny of each individual fluctuated around an average or typical size, as had the commercial varieties, but that while some strains were exactly the same in average size as the commercial variety, others fluctuated around a larger mean or a smaller mean than the commercial variety. He tried the experiment of selecting from these large and small strains extreme variants, and found that no advance was made as a result of the selection. He was thus led to conclude that in a pure self-fertilized strain from a single plant—what he called a pure line—no advance could be made by selection and that the commercial variety with which he first experimented was a mixed race. In the course of his experiments with pure lines, several variations were obtained which reproduced true to type, but these were interpreted by him as changes of type by mutation.

While, before the publication of Johannsen's results, breeders clearly recognized the importance of determining individual performance and using pedigree methods, still his pure-line conception was a distinct advance and forcibly brought to attention the fact that most commercial varieties and races consist of a number of distinct types—biotypes, as he called them,—and that much of our work of selection consists merely in isolating and purifying these types.

Is one, then, to conclude that the practice of breeders in continually selecting from the best for propagation is useless, and must one advise practical breeders to discontinue their selection? There can be no doubt that the practical breeders have made advances by selecting from the best individuals. No scientific breeder will deny this. It is simply the question of the interpretation of how the results were secured that is in doubt and whether these results can be considered as permanent new unit-characters.

It appears that one is dealing in breeding with two markedly distinct types of selection, based on different principles and arriving at different results, both correct in principle and productive of equally valuable practical results, but of very different value when considered from a strictly evolutionary standpoint. The first of these types would be that in which mutations are selected and new races established, while the second would be illustrated by that type of selection which is intended merely to maintain a maximum strain of the race.

It would seem that such cases of improvement as are illustrated by the sugar-beet indicate that the continuous selection, generation after generation, of maximum fluctuations shown by a character, will result in maintaining a strain at nearly the maximum of efficiency; and that within a pure race the progeny of a maximum variate which would probably be classed as a fluctuation, does not regress entirely to the mean of the race in the first generation succeeding the selection, but that there is only a certain percentage of regression similar to the regression determined by Galton.

These races or selected strains maintain themselves as long as the selection is continued, and when the selection is discontinued rapidly regress to the mean of the species.

The practical breeder should clearly recognize that the act of selection, the choice of the best, remains just as important whether it has a cumulative effect, thereby augmenting the character, or whether he is merely purifying an already existing superior race. The final result remains the same.

#### Methods of selection, or pedigree breeding.

By methods of selection is meant those practices that the breeder uses to find promising variations, determine their value, and purify or develop them into fixed races coming true to seed.

##### *Choosing superior plants.*

The first concern of the breeder is to find the valuable variations. How he had best do this will depend largely upon the plant with which he is working. In all cases, it is of the greatest importance to find the best possible plants and this is likely to require the examination of a very large number of individuals. This factor cannot be too strongly emphasized. If, for example, one attempted to find a man 7 feet high, one would probably

have to examine, or pass over, a million individuals to find him. The superior individuals fitted to be the progenitors of a new or improved race are very few. Certain individuals far above the average may be found by examining a comparatively limited number, but the very best possible individual is but rarely produced.

The plants from which selections are to be made should be grown under as uniform conditions as possible, so that the experimenter may have opportunity to examine and select the best. Two methods of growing plants for selection are in general use, and may be termed the nursery method and the field method.

*The nursery method*, which was first used by Hallett about 1868, consists in cultivating each plant under the most favorable conditions possible for its best development. By this method with wheat, for example, Hallett pursued the policy of planting the individuals in squares a foot apart, which would give each plant abundant opportunity for stooling, and also the investigator an opportunity clearly to distinguish each individual plant and determine its characteristics, total yield, and so on. In recent years, this method of growing the individual plants at a standard distance from each other, in order to test their yielding capacities and the like, has been used very extensively.

*The field method* was used by Rimpau about 1867, and probably by many others before that time. By this method, the selections are made from plants grown under normal field conditions. The advantages of this method are that it can be judged only what a plant will do in the field under ordinary conditions of field culture, by growing and selecting it under these conditions. In the large majority of cases, the first selections are probably made from plants grown in the field in the regular course of crop-production, which thus were not specially grown for the purpose.

If one is to use the nursery method, the plants must be especially planted. While the nursery method certainly allows the breeder to distinguish the individual plants more clearly, in wheat, oats, and other crops that are sown broadcast or drilled, it entails very much extra work and is probably to be recommended only for the use of experimenters who are giving their entire time to the work. In the greater number of horticultural crops, the individuals are normally cultivated one in a place, as in the case of tomatoes, cabbages, strawberries, currants and the like, and the examination of individuals in the field thus satisfies the requirements of both the above methods.

The breeder may have in mind either of two purposes in his work: (1) On the one hand, he may desire to secure an improved strain of a certain race, that is, by selection to keep his seed up to the maximum of efficiency. This may be called strain breeding. (2) On the other hand, he may desire to produce an entirely new race with different characters, and this may be called race-breeding.

He should clearly recognize which of these types of breeding he is following. As an illustration, suppose that the breeder is growing the Stone tomato and desires to maintain the best-yielding strain possible of this race. He would then attempt to choose from a very large number of plants of the Stone variety, the best-yielding plants having the largest number of perfect fruits and typical of the variety in habit of growth, quality, character of fruit, and the like, and would hope by a process of continuous selection to maintain his selected strain in a state of high productivity. This is the type of selection pursued by the sugar-beet breeders described earlier in this article.

On the other hand, if he desires to produce an improved new race, he would search among large numbers of tomato plants of any or all varieties for the appearance of mutations or sports, or plants of new type differing from any known variety. As a matter of experience,

it should be stated that it is very easy to find types of plants differing from the varieties or races ordinarily grown, but far the larger part of such variations are worthless types. Good new types, the superior or even the equal of the known varieties, are of very rare occurrence.

If the general improvement of a variety is the breeder's purpose, he should choose a considerable number of apparently superior plants of good type, which will form the basis of his selection work. Breeders who are conducting careful experiments will find it necessary and desirable to use careful methods of judging their plants. While one is breeding possibly for one primary improvement, as, for example, increased yield, it is necessary, at the same time, that one should keep the product up to the standard in other characteristics, namely, quality, disease-resistance, drought-resistance, and the like, and that one sees that all of the good qualities of the variety are retained. To do this properly necessitates the use of a score-card, on which each character of the plant that is important is given its relative weight or grade. By the use of such a score-card, the breeder can judge each character separately, and by the adding up of the score-card get the rank of different plants in a comparative way.

*Inheritance test.*—When a number of plants have been chosen, the next important factor is to test each individual as to its inheritance. It must be continuously remembered that a plant is valuable only as it produces good progeny. To determine the inheritance, the usual method is to plant the seed from each individual selected in a row by itself, or in a marked part of a row. This is the so-called "plant-to-row" method, and brings the offspring of a single individual together so that they may be readily compared with each other and their qualities carefully judged. These progeny rows should be grown in a special breeding-patch in which the soil is as uniform as can be secured.

It is frequently found that two select plants that are equally good so far as their yield is concerned will give progeny that, as a whole, differ greatly in this respect. In the progeny of one, almost every plant may have inherited the desired quality, while in the progeny of the other only a few of the plants may show, in any noticeable degree, the inheritance of the quality. To determine the degree of inheritance, it is necessary to grade carefully the progeny of each individual.

Finally, with the use of his best judgment, the breeder determines the superior progenies, and these would be the ones which have most nearly given the ideal type and produced the best yield of the highest quality. This would end the work of the first generation of the selection as the breeder now has the data which shows him which of the original plants selected was the superior one. It will be seen that this is a method of judging the individual by its progeny.

#### *Continuation of the selection the second year.*

Having determined the superior progeny or progenies at the end of the first year, the breeder then makes his selections of seed-plants from these best progenies for continuing the breeding. While one progeny may be and usually is superior to all others, this may be due to the season or other accidental conditions and for a few generations it is usually the best policy to make selections from several of the best progenies. Select from each of the superior progenies several of the best plants, using the same care in selecting these plants as was used in choosing the first plants. Preserve the seed from each of these plants separately and keep it carefully labeled so that its origin may be known.

The further work with these plants consists in planting each individual by the plant-to-row method, testing the inheritance as described in the first generation, and finally selecting again the best progenies. This would be followed by again selecting from the best pro-

genies a number of superior individuals to continue the selections in the third year.

The third and succeeding years of the selection would be conducted in the same way as long as it was thought necessary or desirable to continue the work.

#### *Securing general stock seed of the improved strain.*

In carrying out selection work as outlined in the preceding section, it is ordinarily the object of the breeder to secure an improved strain of the race with which he is working, and usually he desires to utilize such improvements as he can make at the earliest possible time. With ordinary annual crops such as beans, peas, tomatoes, corn, and cotton, it will be found a good policy at the end of the second year of the selection, after taking the seed from the few special plants used in continuing the pedigree breeding, to harvest the seed from a number of the best plants remaining in the chosen progenies and using this seed to plant a multiplication plat from which stock seed may be secured to plant a fairly large crop. Each year following this, seed may be taken in the same way from the best progenies in the breeding patch to plant a multiplication plat. By this method, seed of a gradually improving grade may be secured for planting a general crop.

#### *Control of parentage.*

In plant-breeding, as in animal-breeding, the isolation of the parents is a very important consideration. It is necessary that the character of both parents should be known whenever this is possible. In breeding plants, more attention is given ordinarily to the mother parent,

and in very many instances the characters of the father parent are entirely neglected. Animal-breeders, on the contrary, give more attention to the characters of the male parent, and much improvement in ordinary herds has been accomplished by the introduction of improved heritage through the male. In plant-breeding, it is desirable that the seed of the select individuals be planted in a field by themselves. This insures that only progeny of carefully selected individuals will be planted near together, and thus no ordinary stock will

642. *Aquilegia* flowers, illustrating the process of emasculation.

a, mature bud showing stage which should be chosen for emasculation; b, similar bud with the tips of the corolla pruned apart and the stamens removed; c, a bud opened naturally, too old to operate on; d, a bud of the stage shown in a and b, with corolla removed to show the internal organs; e, a bud the same as in d, but with the stamens removed; f, the same as e, but older, at the age when pollination normally takes place; g, pistil shortly after fecundation, the remnants of the stamens having fallen away.

enter as a contamination. One can be certain that each plant of the progeny is fertilized with pollen from another similarly good plant, or at least from a plant derived from good parentage. One difficulty, however, has been experienced by plant-breeders in planting continuously their selected stock in such isolated plats. If this method is continued year after year, it results in fairly close inbreeding, which, in the case of plants, frequently results in loss of vitality and vigor. In animals there is frequently no noticeable effect from close inbreeding, and many of the most famous animals have been produced as a result of the closest in-and-inbreeding. In plants, however, it is possible to secure much closer inbreeding than in animals, as in many cases a plant can be fertilized with its own pollen.

Within recent years, much activity has been shown

in the careful breeding and improvement of corn. The corn plant has been shown, as a result of experiments made by various investigators, as, for example, the Illinois Experiment Station and the United States Department of Agriculture, to lose vitality very rapidly when self-fertilized. Within three or four generations, by the most careful inbreeding, it is possible to reduce corn almost to total sterility. The

643. Plant of aquilegia with flowers covered with bags in hybridization work.

general practice of corn-breeders who have been giving attention to the production of pedigree strains is to plant the rows of corn from different select ears side by side, giving a row to each select ear, and each year selecting, from the progeny of those rows that give the largest yield, plants to continue further the selection. Planting these select ears together every year, therefore, means that they are more or less inbred, as the closest relatives are planted together in the same row. While in following this practice at first no effect was visible, corn-breeders are now finding in some cases an apparent decrease in yield, which seems

to be traceable to the effect of inbreeding. It seems necessary, therefore, in corn and in other plants that are affected by inbreeding, to use methods that will avoid close inbreeding. The detrimental effect of inbreeding is largely limited to those plants that are normally cross-fertilized, this fact being strikingly brought out in Darwin's "Effects of Cross and Self Fertilization in the Vegetable Kingdom." Tobacco, wheat, and some other plants that are normally self-fertilized do not show this decrease in vigor as a result of inbreeding.

Considerable effort has been made within recent years, in the selection of certain crops, particularly corn, to follow both parents, choosing good males and good females of known parentage and crossing these by artificial means. There can be no doubt but that by the use of such methods more rapid progress could be made, but in the greater number of cases the methods thus far devised require so much work as to be almost prohibitive.

A method of breeding has recently been devised by J. B. Norton in the improvement of asparagus, which is worthy of careful consideration and may be applicable, at least in modified form, to use in the improvement of various crops. Asparagus is dioecious, the male and female flowers being borne on different plants. The first part of the process consists in selecting a number of superior plants of both sexes, attention being given to all important characters such as yield, quality, rust-resistance, and the like. This having been done, the next process consists in crossing each female with each selected male plant and testing the progeny produced by the cross. If, for example, ten superior females and ten superior males were chosen, a sufficient number of flowers on female No. 1 would be crossed with pollen of each of the ten males to obtain sufficient seed to test the comparative value of the progeny of female No. 1 with each of the ten males. The ten lots of seed from the crosses on female No. 1 would be grown separately and the comparative value of the different progenies determined by careful observations on vigor, rust-resistance, quality of product, yield, and the like. In this way, it would ultimately be determined which of the ten male plants was the superior one to use in crossing with

female No. 1. In like manner, female No. 2 would be crossed with each male and the progenies tested to determine the superior male in this combination. Finally the combination of each female with each male can be compared and if the work has been conducted with sufficient care and for a long enough period, it can be determined which combination has uniformly given the best results.

Asparagus is perennial and is easily propagated vegetatively by separation of the roots, so that when once the superior male and female combination has been determined, these may be propagated vegetatively as clons, in alternate rows in an isolated place so that all seeds developed will be of the desired combination. Asparagus produces numerous seeds and by such a method an indefinite quantity of seed of the desired combination can be produced. It would doubtless be possible in a few years, if desired, to have all of the seed used commercially grown from a single superior combination.

If experiments of this nature could be made on an extensive scale so that the males and females of the highest or maximum grade could be discovered, they would be of almost fabulous value. The importance of this method of breeding may be better appreciated by imagining the value of the best bull and the best cow in the world if they would live indefinitely and if it were possible for them to reproduce rapidly enough to supply all of the individuals desired.

The direct application of this method is possible only with perennial dioecious plants that can be propagated as clons and that develop numerous seeds. The hop is another plant to which this method of improvement could be applied.

### Hybridization.

Aside from selection, hybridization has played the most important rôle in the formation of the varieties and races of our cultivated plants; but the results obtained are in many cases closely connected with selection. Ever since the time of Knight, hybridization has been used extensively in plant-breeding, and it seems that this is the only sure means that the breeder can use in producing new and desirable combinations of characters. In hybridization, as generally used, the breeder does not expect to cause or produce new unit-characters, although such changes may occasionally occur under the stimulus of hybridization. What he can do with certainty is to secure hybrids combining the different characters of two distinct sorts. The extent to which such recombination of characters can be carried is almost unlimited. In many cases, two or three or even four distinct species and the characters represented in their various varieties have been recombined in hybrids.

In older literature, the term hybrid was restricted to crosses resulting from the combination of distinct species, while combinations of different races of the same species were known as crosses or mongrels. The term hybrid is here used as designating any product of a cross when the parents were noticeably distinct from each other, whether the parents belonged to different clons, races or species. This broader use of the term hybrid has become almost universal in recent years. If, in discussion, it is necessary to refer to the degrees or grades of difference in the parents, the hybrids may be characterized as species hybrids, racial hybrids, clonal hybrids and the like.

### Choosing varieties to hybridize.

In starting any work in hybridization, the first important step is the choice of the varieties to be hybridized. It is interesting to make crosses of any two plants with distinct characters and observe the recombinations of characters which result, but this haphazard work takes too much time and is not to be recom-

mended. The breeder, in general, should hybridize with some definite aim in view and use systematic methods in attempting to accomplish that aim. One cannot ordinarily expect to obtain in hybrids of any two varieties any characters which are not present in the parents. The unit-character conception explained in the beginning of this article is of fundamental importance in understanding hybrids. The breeder, by a careful study of varieties, determines the good characters and the poor or weak characters of each variety. He may, as an illustration, if working with tomatoes, find all of the varieties with yellow pear-shaped fruits to be large bushy plants, the so-called standards, and he may desire a dwarf type of plant and red fruits. By examining the different races of tomatoes, he would soon find a variety, such as the Quarter Century, which possesses the characters of dwarf plant and red fruit. By crossing these two varieties, he would obtain new combinations of the characters of the two sorts, and if he grew a sufficient number of the second generation of these hybrids, he would be certain to find some plants in which the pear-shape had been combined with the red color and dwarf habit of the Quarter Century variety.

The study of the varieties of any crop thus gives the breeder an idea of the characters available, and he must then use his originality and judgment in determining what combinations of these characters would form the best commercial variety. If this combination does not already exist, he may start out with considerable confidence that it is possible for him to obtain such a combination and thus a valuable new variety. Plants, however, are not simple in their organization and the reaction of different characters on one another in different combinations may not always be what one expects. Again, in no plant has a complete analysis been made of all characters, and it may be impossible for us ever to reduce all the characters of a plant to a unit-character basis; thus there is always an element of doubt as to the value of any new combination of characters until this combination has been produced and tested.

#### *Methods of crossing plants.*

Plants, like animals, bear male and female organs, and an act of fecundation is necessary in all ordinary cases to insure the development of seeds. In probably the larger number of plants, the male and female organs or the stamens and pistils are borne in the same flowers on one plant. In some cases, as in the castor bean, corn, and the like, both sexes are borne on the same plant but in different flowers. In still other cases, as in the date palm, asparagus, hop and hemp, the sexes are on different plants.

In hybridizing plants, it is necessary to insure that the plants are not fertilized with their own pollen or with pollen from any other source than that desired. If, therefore, the plant to be operated on has the stamens and pistils in the same flower, the stamens must be removed from the buds before they burst and discharge the pollen. This act of removing the stamens, or emasculation, as the process is called, is necessary in order to prevent self-fertilization. In some plants, it is necessary to emasculate the buds very early, as the pollen develops considerably in advance of the pistils. In other cases, the pistils reach maturity or a receptive condition before the pollen is shed. In this latter case, the emasculation may be delayed until a time just previous to the normal opening of the flower.

The process of emasculation may be illustrated by the columbine. Here large-sized buds are chosen just before they open normally (Fig. 642). The tips of the petals can then be easily pried apart so that the stamens may be pulled off with small forceps. This process should be performed carefully to avoid crushing or injuring the pistil. The bud should then be inclosed in a small light paper bag in order to prevent pollen from any foreign source being brought to the pistil by insects or wind (Fig. 643). The bud should remain covered until sufficient time has elapsed to allow the pistil to reach normal maturity, when the bag should be removed and the pollen from the desired variety dusted over the pistil. After this act of pollination, the bud should again be covered with the paper bag, which should not be finally removed until several days later, after fecundation has taken place. As soon as a flower is pollinated, it should be labeled with a small tag of some sort which may remain attached to the flower-stem until the fruit is ripe. In some cases, the pollen may be placed on the immature pistil without injury, when the flower is emasculated, and this is a great saving of time when it can be done. However, in most cases, premature pollination is liable to injure the pistil and prevent the setting of seed. One should ordinarily attempt to pollinate the pistil at as nearly the normal time as possible. Many

plants are difficult to hybridize and every process must be as natural as possible to insure results.

Many handy methods have been devised to use in pollination work and are described in breeding literature. In all work fine copper wire is better to attach bags and labels than is string. In emasculation work also, it will often be found convenient when some pollen has accidentally fallen on the pistil to wash it off with water by means of a small dental syringe. In many cases, such as apples, pears and cotton, the best means of emasculation is to remove the outer floral envelopes by cutting them off, using a sharp scalpel. With a little practice this can be done quickly and with minimum injury to the essential organs (Fig. 644).

Difficulty is frequently experienced when hybridizing different varieties, in getting plants of each variety to bloom at the same time. This difficulty may be overcome in many cases by keeping the pollen, which can be done for a limited period by slightly drying the pollen without allowing it to become desiccated, and preserving it in a tightly corked bottle.

After the pollen has been placed on the stigma of the pistil by the act of pollination, each pollen-grain develops a small tube which grows down through the pistil to the ovary. Through this tube, the male germ-cells pass down and finally a male germ-cell comes in contact with each egg-cell of the different ovules in the ovary (in most plants there are several ovules in each ovary) and fuses with them. This constitutes the act of fecundation or fertilization. This fecundated egg-cell is then the beginning of the hybrid and from the seed containing it, when grown, there develops the hybrid plant. The plant developed directly from this hybrid egg-cell is known as the first-generation hybrid ( $F_1$ ). Seeds from this first-generation hybrid, when grown, give second-generation hybrids ( $F_2$ ). The expressions  $F_1$ ,  $F_2$ , and  $F_3$ , meaning first, second and third filial generations, are used very commonly to designate the first, second and third generations of hybrids.

#### *Laws of inheritance in hybrids.*

When plants of different pure races are crossed, as, for example, different races of wheat, corn or cotton, the hybrids are usually all very similar to each other in the first generation, exhibiting in general the same characters. And this is the case also when different fixed species are crossed. If, however, individuals belonging to unfixed races are crossed, there is usually a considerable variation in the first generation. This is well illustrated by the crossing of different clones of apples, pears, oranges, and the like, when the different so-called varieties are merely transplanted parts of the same individual seedlings which have not been bred to a purity of type. It is well known that if seeds of an apple variety be planted, the resulting plants exhibit many different variations in the first generation. The parents, themselves, therefore, not being of pure type, when they are hybridized produce progeny which in the first generation is variable. In the crossing of races which have been bred true to type, whether of the same or of different species, the first-generation hybrids, however,

644. Cotton flowers, illustrating the process of emasculation.

a, mature bud showing the stage which should be chosen for emasculation; b, a similar bud with the corolla cut off ready to emasculate; c, a similar bud with the stamens removed,—emasculated.

are nearly uniform in the characters presented, and in such instances it is necessary to secure a second generation of the hybrids in order to accomplish the segregation of the characters and the production of a large number of variations. Ordinarily, therefore, desirable variations are looked for in the second generation. This, as has been explained above, is true only in the case of hybrids of species and races that are fixed in type.

*Mendel's law of hybrids.*

The preceding discussion represents fairly well the general understanding of hybrids until about 1900, when DeVries and Correns rediscovered what is now termed "Mendel's law of hybrids." These laws or principles are of great value from an economic standpoint, and are, furthermore, of the greatest scientific interest. They should thus be thoroughly understood by every practical breeder of plants. It has been known for many years that a splitting-up and redistribution of parental characters occur in hybrids, and it is on this fact largely that the practical application of hybridization in plant-breeding depended. Until Mendel's law was discovered, however, there was no understanding of why or how such a recombination could be made, and it was necessary to experiment extensively in order to determine what could be accomplished.

If one carefully studies a number of first-generation hybrids with special reference to the characters of the parents exhibited in the hybrids, it will be found that certain characters possessed by the male parent are plainly represented in the hybrid, while other characters possessed by the female parent are also represented in the hybrid. Many characters of the parents are thus plainly represented in the hybrid, but it is probable that other characters will be blends of the similar parental characters, or possibly differ from any definite characters distinguishable in the parents. Attention has already been called to the complexity of organisms in general and the difficulty of recognizing all of the unit-characters. Thus far it has been possible only to follow carefully certain plainly marked characters. This commingling of the different characters of each parent gives the hybrid a mosaic appearance, as if certain characters had been taken from each parent and thrown together to make up a hybrid individual.

*Character-pairs.*—To understand this commingling of characters in the first-generation hybrids, it is necessary to know that the parents used in the hybridization differed from each other in certain characters. One parent may have had red fruits, hairy stems, and dwarf habit, while the other may have had yellow fruits, smooth stems, and tall habit. Such characters are opposed to each other, and such opposed qualities or characters are termed "character-pairs." A plant may have red fruits and smooth stems, but it could not have red fruits and yellow fruits at the same time. As an illustration of such character-pairs, may be cited, scarlet and yellow fruits of peppers, reversed or erect fruits of peppers (Fig. 645), starchy and sweet kernels of corn, standard and dwarf size in tomatoes, stringy and stringless pods of beans, and the like. Such pairs of characters have been termed by Bateson "allelomorphic pairs of characters," and this terminology is commonly used in the literature on hybrids. When parents possessing opposed or contrasted characters are crossed, the hybrid egg-cell receives, through the male and female germ-cells uniting in the fecundation, the determiners which represent the different contrasted pairs of characters, and all cells making up the first-generation hybrid will contain in like manner the determiners representing these characters, and are thus hybrid in nature. This

being the case, it might be expected that all characters in the hybrid would show as blends of the parental characters or exhibit some stage of intermediacy between the characters of the parents. This is indeed frequently the case, but more commonly one of the characters is very strong, or "dominant," as Mendel expressed it, and only this character will show in the first-generation hybrid, the other character remaining recessive or masked, although present. As an illustration, in the character-pairs mentioned above, scarlet fruits of pepper, reversed fruits of pepper (this is true only in certain varieties), starchy kernels of corn and standard size of tomato plants, are dominant over their corresponding contrasted characters. Illustrations of blended or intermediate characters are found, for example, in first-generation hybrids of round with pear-shaped tomatoes, and large with small fruits of tomatoes or peppers.

*The law of segregation and purity of the germ-cells.*—The second important principle of Mendel's law is what is termed the law of segregation and purity of the germ-cells. It seems certain from the researches that have been conducted that, when the germ-cells of the first-generation hybrids are formed, the determiners which represent the two different characters under consideration, and which were united by the hybridization, ordinarily segregate again in the cell-divisions, which lead to the formation of the germ-cells, so that certain germ-cells include the determiner of one only of the two characters. There are thus two kinds of germ-cells formed with respect to this one character-pair. Choosing as an illustration a hybrid of a pepper having scarlet fruits with one having yellow fruits (Fig. 645), when the germ-cells were formed a segregation of the determiners representing the two opposed characters would take place and there would be germ-cells of one kind, both male and female, containing the scarlet fruit determiners and of a second kind, both male and female, containing the yellow fruit determiners. This segregation takes place in the formation of both the egg-cells and the sperm-cells or pollen-grains. It is thus seen that the first-generation hybrid, when two such allelomorphous characters are combined, forms two kinds of egg-cells and two kinds of sperm-cells, so far as this one character-pair is concerned. This segregation of characters, which has been termed the law of segregation, is one of the most important facts of inheritance and, in enabling us to get recombinations of characters, is of the highest importance in breeding.

*The law of probability in recombination of characters.*—The third important principle of Mendel's law is what is termed the law of probability, and explains what may be expected in plants of the second generation of such a hybrid. Remembering that there are formed in the first-generation hybrid, as explained above, two kinds of egg-cells and two kinds of sperm-cells with reference to the opposed characters, what would happen if the hybrid were bred with its own pollen; or, in the case of an animal, if it were bred with another hybrid of the same parentage? For the purpose of illustration, suppose that a hybrid of a scarlet-fruited pepper with a yellow-fruited pepper be fertilized with its own pollen, and that 100 egg-cells be fertilized with 100 pollen-grains of the same hybrid. There are two kinds of egg-cells produced, some carrying determiners of the scarlet fruit, and others determiners of the yellow fruit, and the same is true of the pollen-grains. Taking the egg-cells and pollen-grains without choice, as equal numbers are produced of each kind, one would expect to have of the egg-cells fifty with scarlet determiners and fifty with yellow determiners. In the pollen-grains, also, one would expect to have fifty with scarlet determiners and fifty with yellow determiners. If, then, the 100 egg-cells and 100 pollen-grains are brought together in fertilization by chance, as would occur in nature, according to the law of probability, there would be twenty-five scarlet uniting with twenty-five scarlet; twenty-five scarlet uniting with twenty-five yellow; twenty-five yellow uniting with twenty-five scarlet; and twenty-five yellow uniting with twenty-five yellow. Representing scarlet determiners by the capital letter S because scarlet is the dominant character, and the yellow determiners by the small letter y, as yellow is recessive, the unions may be represented as follows:

## ONE HUNDRED EGG-CELLS BY 100 SPERM-CELLS.

Female Cells	Male Cells	Composition of hybrids	
25 S	× 25 S	= 25 SS	These do not contain determiners of y and will reproduce true.
25 S	× 25 y	= 25 Sy	
25 y	× 25 S	= 25 yS	These are hybrids so far as this character-pair is concerned,—exactly the same as in the first generation and contain determiners of both S and y. These will not reproduce true to type and will break up like second-generation hybrids.
25 y	× 25 y	= 25 yy	
			These do not contain the determiners of S, and will reproduce true.

The above illustration explains the law of segregation, and the probable ratio of recombination when hybrids are inbred with their own pollen, and when only one pair of characters is considered. When an egg-cell with scarlet determiners unites with a sperm-cell with scarlet determiners, this gives rise to a pure germ-cell, or zygote, containing only scarlet determiners, and the progeny in subsequent generations will breed true so far as this character is concerned. Also, when an egg-cell with yellow determiners unites with a sperm-cell containing only yellow determiners the result is a pure germ-cell, containing only yellow determiners and the progeny would reproduce true, so far as this character is concerned, in subsequent generations. In the other two cases, when in fecundation

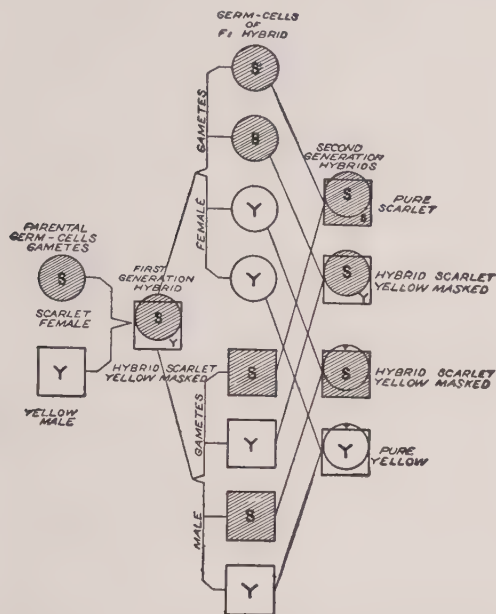

645. Pepper plants: *a*, with scarlet-colored reversed fruits; *b*, with yellow-colored erect fruits. The number and form of branches are also markedly different.

gametes with scarlet determiners unite with gametes with yellow determiners giving the combinations Sy and yS, which amount to the same thing, there result in reality, hybrids exactly the same as in the first generation and the progeny from these in the next generation behave exactly the same as did the first-generation hybrids in the second generation.

In such a case as the one under consideration, in which the scarlet is a strong dominant character, all combinations that contain the determiners of this character, whether pure or of hybrid nature, show this character only. Thus in the above 100 combinations the twenty-five yy would come with yellow fruits while the seventy-

646. Representing Mendelian inheritance of scarlet S, and yellow Y, color of fruits in pepper hybrids.

five other combinations would have scarlet fruits, although fifty of these would be of hybrid nature. To determine which of these seventy-five scarlet-fruited plants are the combination Sy, that is, scarlet with yellow, and which are SS, that is, scarlet with scarlet, requires the growing of self-fertilized progeny from them to determine which are reproduced true to type, as these would be the pure scarlet. The progenies of any of these plants that produced both scarlet- and yellow-fruited plants would show that the parent of such progeny was a hybrid.

In the hundred combinations there is thus produced a ratio of one pure scarlet to two hybrid scarlet and yellow to one pure yellow, 1 SS:2 Sy:1 yy, or three scarlets to one yellow and this is the famous 3:1 Mendelian formula.

This process of union of an allelomorph pair of characters in hybridization, the formation of four kinds of germ-cells, both male and female, by the hybrid, and their four different unions, is graphically illustrated in Fig. 646.

While in certain hybrids of parents possessing two opposed parental characters, this ratio of probabilities is not produced, if large numbers are used the ratio will be found in many cases with little deviation. A sufficiently large number of cases have now been studied with various plants and animals to place this conclusion beyond question. It is not known, however, how many characters follow Mendel's law, nor is it yet entirely certain whether those character-pairs that sometimes follow the law of segregation always follow it.

The individuals of the second generation which contain the determiners of both characters of the pair, if self-fertilized or bred with similar individuals containing the determiners of both characters, exhibit in the third generation exactly the same nature that first-generation hybrids exhibit in the second generation. The two determiners are commingled in their cells, and to all intents and purposes they are exactly the same as first-generation hybrids. When such self-fertilized hybrids are grown they give again, in the third generation, the regular Mendelian proportion of 1 SS:2 Sy:1 yy. Here the individuals containing only determiners of one character, that is, SS and yy, would come true to these characters in succeeding generations, while those individuals containing the determiners of both characters, S and y, would be expected to segregate again in the fourth generation in similar proportions.

When dealing with more than one character-pair, ratios of segregation become complicated but are easily understood. If the character of reversed fruits (R) and erect fruits (e), two plainly marked characters of ordinary garden peppers, caused by the pedicel of the fruit curving backward in one case and remaining straight in the other, are combined with the above allelomorph

characters, it can be foretold exactly what combinations will occur and the relative number of each. This is a second allelomorph pair of characters that behaves in inheritance the same way as did the two colors of fruit. In this case, the reversed pedicel is the dominant character, as in the F<sub>1</sub> hybrids of reversed with erect sorts the pedicels are always or very generally recurved. These characters would thus be represented by R for the recurved or dominant character and e for the erect or recessive character. In this character-pair one would expect a splitting and segregation to have occurred in the formation of the germ-cells of the first generation so that the hybrid plants of the second generation would exhibit these characters in Mendelian proportions as in the character-pair first described. The progeny in the second generation would thus exhibit these characters in the following combinations and proportions: 1 RR:2 Re:1 ee. This theoretical proportion should hold rather constantly, either in small or large numbers of hybrids, though in large numbers it would be more nearly realized. The determiners of the four characters, or two character-pairs, are commingled in the cells of the first-generation hybrid. When the egg-cells and pollen-grains are formed, however, a segregation of the determiners of the two character-pairs occurs, but independent of each other. Each egg-cell or pollen-grain will receive only the determiner of one character of a certain character-pair but will, at the same time, receive determiners of other characters belonging to other character-pairs. Considering the two character-pairs described in peppers, an egg-cell receiving the determiner of the scarlet color of fruit S, might also receive the determiners for either R or e representing the characters of recurved or erect fruits. These two character-pairs would thus give egg-cells of four combinations, SR, Se, yR, and ye.

In the formation of the pollen-grains, the same combination occurs, so that with reference to the two character-pairs described, the pollen-grains that would be formed have the same combinations of determiners as the egg-cells, namely, SR, Se, yR, and ye. There would thus be four kinds of egg-cells and four kinds of pollen grains so far as these two character-pairs are concerned. If these are brought together, sixteen combinations are possible as follows:

SRSR	SeSR	yRSR	yeSR
SRSy	SeSy	yRSy	yeSy
SySR	SySe	SyRS	SySe
SySy	SySe	SyRS	SySe

Examining these combinations carefully, and placing together those combinations that contain the same character-determiners as indicated by the letters, and this can properly be done as it does not matter in the fecundated egg whether a certain determiner is furnished by the egg-cell or the pollen-grain, there result the following nine combinations, all of which are different in germinal constitution with reference to these two character-pairs:

TABLE SHOWING NUMBER OF GERMINAL COMBINATIONS AND CHARACTER OF F<sub>2</sub> PEPPER HYBRIDS WITH TWO ALLELOMORPHS.

No. of combinations	Germinal constitution	Visual characters of hybrid	Nature of hybrid
1	SRSR	Scarlet recurved	Pure scarlet and recurved
1	SeSe	Scarlet erect	Pure scarlet and erect
1	yRyR	Yellow recurved	Pure yellow and recurved
1	yeyy	Yellow erect	Pure yellow and erect
2	SRSy	Scarlet recurved	Pure scarlet and hybrid recurved x erect
2	SySR	Scarlet recurved	Hybrid scarlet x yellow and pure recurved
2	SySe	Scarlet erect	Hybrid scarlet x yellow and pure erect
2	yRyS	Yellow recurved	Pure yellow and hybrid recurved x erect
4	SySe	Scarlet recurved	Hybrid scarlet x yellow and hybrid recurved x erect

An examination of the preceding table, in which are grouped the sixteen possible combinations when two allelomorph pairs are concerned in the hybridization will show that among these sixteen there are nine groups with different germinal constitutions. The visual character of the hybrid plants of these nine different groups is given in the third column and is easily understood by examining the germinal constitution and remembering that scarlet S, and reversed R, are the dominant characters in the two allelomorphs and that the presence of one determiner of either of these characters will cause the appearance of that character in the hybrid plant. It will be observed that by grouping the hybrid plants according to the characters they show, there will be nine scarlet and reversed, three scarlet and erect, three yellow and reversed, and one yellow and erect. This is the Mendelian formula: 9:3:3:1. The nature of the nine different groups of hybrid plants with different germinal constitution is given in the fourth column of the table. When a character is pure, it may be expected to reproduce true in succeeding generations but in those cases in which both determiners of a character-pair are present, the character is of hybrid nature and will segregate in succeeding generations.

In the illustration of the character-pair, scarlet and yellow fruits and the probable ratio of number of unions in F<sub>2</sub> hybrids, it was shown that out of 100 unions one should expect 25 SS:50 Sy:25 yy. If now the second character-pair recurved and erect fruits is con-

sidered in connection with these same 100 unions, there would occur the following combinations, according to the law of chance:

25 SS	50 Sy	25 yy
$6\frac{1}{4}$ SRSR	$12\frac{1}{2}$ SRyR	$6\frac{1}{4}$ yRyR
$12\frac{1}{2}$ SRSe	25 SRye	$12\frac{1}{2}$ yRye
$6\frac{1}{4}$ SeSe	$12\frac{1}{2}$ Seye	$6\frac{1}{4}$ yeye

These nine combinations are the same as given above, but the percentage of each combination out of the 100 unions is shown.

If a third character were considered, the proportions of the combinations can be determined in exactly the same way. Each one of the above nine possible combinations would be again divided into three different unions in the same way as the three combinations of the one character-pair gave nine different combinations with the second character-pair. In the consideration of the three character-pairs, there would thus be twenty-seven different combinations of parental characters. And again in each ovary fecundated, when only one determinant of each character-pair occurred, the opposing character-determiner being in each case eliminated, such a cell should give a plant that would reproduce its character true to type. It is well known that almost any two different races or species that may be chosen for hybridization will ordinarily differ from each other in numerous characters. When there are a

647. Pepper hybrids distinct from parental types, formed by recombination of characters; *a*, dwarf type with few small horizontal branches; *b*, giant type with many large erect branches.

number of these opposing characters which form Mendelian character-pairs, the determination of the possible combinations by Mendel's formulae becomes very complex and difficult to understand. It is only by taking a few well-marked character-pairs and carefully studying them that the segregation and new combinations according to Mendelian proportions can be followed and understood.

Any character-pairs following Mendel's law would segregate as indicated above, in the case of scarlet and yellow fruits and reversed or erect fruits of the pepper. A very large number of characters of various plants and animals are now known to be Mendelian and while many modifications of the principles have been necessary to harmonize them with special cases, still it may be said that there is no other general law of heredity and Mendel's law has thus furnished us with a working basis of great value.

The study of hybrids has been resolved into a study of unit-characters and their relation to each other. By hybridizing related types having opposed characters and observing the segregations which occur in the later generations, the characters of each type are analyzed and it is determined when a character-pair occurs. The researches on this subject by Mendel, Bateson, Davenport, Castle, Punnett, Shull, Hurst, Correns, Tschermak, East and dozens of other now well-known investigators, have developed a science of heredity of which there was no conception a few years ago.

The characters presented by the different varieties of a plant or of different species, which can be crossed with it, can now be studied, and one can definitely plan the combination of characters desired in an ideal type, and can with considerable confidence estimate the number of plants it will be necessary to grow to get this combination. It is now known in general how characters behave in segregation and inheritance, so that one can go about the fixation of a desired type, when one is secured, in an orderly and intelligent way.

The further the study of characters is carried, the more it is coming to be realized that the appearance of apparently new types following hybridization is due to recombinations of different units which in their reactions give apparently new characters. As an illustration, in a study of pepper hybrids, which has been conducted during the past four years, it has become evident that the form of plant and branching is due to three pairs of characters or allelomorphs; namely, first, erect or horizontal branches; second, large or small branches; and third, many or few branches. In crossing two medium-sized races, one with large horizontal and few branches, and the other with small erect and numerous branches, there result many new combinations of characters, among which appear some with small horizontal and few branches, which gives a dwarf plant, and others will have a combination of large erect and numerous branches, which gives a giant plant (Fig. 647). These dwarfs on the one hand and giants on the other appear as distinct, new creations, though they are very evidently merely the recombinations of already existing unit characters, and dwarfness and giantness are the results of the reaction of the different units combined.

When the large number of distinct characters that are presented by the very numerous varieties of any of our cultivated plants is remembered, an understanding is secured of the possibilities of improvement which the field of hybridization affords.

### The development of hybrids into pure races.

When hybrids have been produced between species or varieties possessing certain characters that it is desired to unite in a variety, the recombinations of characters as explained in the preceding section become visible in the second generation, and it is thus among the plants of this generation of the hybrid that one should expect to find the combination of characters desired. The breeder would thus very carefully examine a large number of second-generation plants and choose for further experimentation those plants that were found to have inherited the characters which he desired to combine. The entire batch of  $F_2$  plants should be carefully examined to determine what characters behave as character-pairs and also the dominant or recessive nature of each character. This knowledge is necessary in order to determine the practice to be pursued in choosing plants in which the characters desired will be pure with reference to these characters. If, for example, the breeder is working to get a combination of two characters only, such for instance as a yellow- and erect-fruited pepper, from the combination of character-pairs discussed above in explaining Mendel's law he would discover that both of these characters are recessive, and thus when a hybrid was found in which these two characters were united, he could be sure that by self-fertilizing such an individual it would reproduce true with reference to both of these characters in the next and succeeding generations. He would know furthermore in dealing with only two pairs of characters that he should, according to the law of chance, secure on an average about one such combination in sixteen hybrids.

If, however, the combination desired was a scarlet reversed fruit, both dominant characters, the process would be much more difficult. As shown in the preceding section describing the segregation and recombination of characters, nine plants out of the sixteen possible combinations would have red, reversed fruits, while only one of the nine would be pure with reference to both of these characters. The breeder would thus be compelled to self-fertilize a number of the plants having red and reversed fruits and grow a number of plants from each in order to determine which one, if any, was pure with reference to both characters. If, then, the progeny from any one of the plants chosen and self-fertilized came true to type with reference to both characters, he would be certain of its purity and would again self-fertilize some of the best plants of this progeny, which should give him a pure type.

If a combination of a dominant and recessive character is desired, the examination of the  $F_2$  hybrids would enable the breeder to choose a pure plant so far as the recessive character is concerned, but he could not determine the purity of the dominant character and would be compelled to self a number of plants exhibiting the two characters and grow progenies in the third

generation, when he should be able to select a pure type with reference to both characters.

If, as frequently occurs, neither character of an allelomorph pair is dominant, but gives in the hybrid an intermediate form, the fixation becomes simple, as in such cases those hybrids in which either character is pure can be recognized.

While these methods appear very complex at first, they will be easily understood with careful study, and are far simpler than the methods breeders were compelled to employ in fixing hybrids before they had an understanding of Mendel's law.

When more than two characters are concerned in the recombination, the process becomes more difficult, and indeed one cannot limit one's consideration to two characters in practical breeding unless one is combining standard varieties where all characters are good. As in simple selection work, one must necessarily consider all important characters that go to make up a good variety, and usually one will be able to recognize Mendelian segregation only in a few prominent differential characters. The breeder should use the knowledge of inheritance that he possesses with all characters which he can recognize, but at the same time the plants which he inbreeds to secure purity of type should be perfect plants of all-round good type, and in every generation of the hybrids grown he should exercise his best judgment in selecting the best plants for seed-bearers.

In the fixation of cotton hybrids, the policy was pursued of selecting for inbreeding the most fruitful and best-shaped plants of those hybrids having the desired characters, using very large numbers of hybrids from which to choose. The self-fertilized seed of a certain type was then planted by the plant-to-row selection method in an isolated plat, in order to give an opportunity to select not only the pure combination of the desired characters but the best all-round plants. As soon as the plants in such an isolated plat were sufficiently developed to show their characters and it could be recognized that certain ones had inherited the desired qualities, the fields were carefully searched and all plants not true to type were pulled up, leaving only a few good plants of the correct type. This process of roguing, as the seedsmen call it, insures that at least the greater part of the seed developed would be fertilized with pollen of similar plants of good type. This sort of selection and purification of type will probably in most cases be found necessary even after such Mendelian characters as can be recognized have been secured in a pure state.

The inheritance of many fundamental characters will doubtless remain obscure for many years.

#### The use of impure first-generation hybrids.

In the case of very many of the most important horticultural crops, fortunately, it is possible to use hybrids without the necessity of purifying or fixing them as described in the last section. Plants such as apples, pears, oranges, grapes, roses and strawberries, which are grown as clonal varieties, being propagated by buds, grafts or slips, are merely parts of one individual and it does not matter whether they are germinally

pure, as seeds are not needed. This makes it possible to use  $F_1$  hybrids and, as hybrids are notoriously vigorous, this is a factor of very great importance. Again, characters which blend and give intermediates in the  $F_1$  generation may, in such cases, prove very valuable.

The work that has been carried out by the Department of Agriculture in the breeding of citrus fruits very clearly indicates that valuable intermediates may sometimes be secured. The writer, in conjunction with Walter T. Swingle, hybridized the hardy cold-resistant trifoliolate orange (*Poncirus trifoliata*) with several varieties of the tender sweet orange, and as a result at least five different varieties of hardy oranges or citranges have been produced. These hybrids are nearly intermediate between the two parents, having the characters in the first generation nearly blended.

The leaves are trifoliolate, but are much larger than the leaves of the ordinary trifoliolate orange tree, and show a tendency to drop off, the lateral leaflets producing an unifoliolate leaf. The trifoliolate orange is deciduous, while the sweet orange is evergreen. The hybrids are semi-deciduous, holding a large share of their leaves through the winter. In hardness they also seem to be intermediate, being much more cold-resistant than the ordinary orange, but not so hardy as the trifoliolate orange. They are sufficiently hardy so that they doubtless may be grown with safety as far north as South Carolina, or 300 to 400 miles north of the present orange region. Some of the

fruits produced are as large as the ordinary orange, but most of them are very nearly intermediate in size. They are very variable, however, in the first generation. At least five of the fruits that have been produced are juicy and valuable. It is not probable that they would be reproduced true to seed, but orange varieties are clonal, and the different types will, of course, be normally reproduced by buds or grafts, so that from a practical standpoint it does not matter whether or not they would reproduce true through the seed. In the second generation it is probable that these different characters would split up, possibly according to Mendel's law, and it is likely that still more valuable varieties will be secured when a second generation has been grown. See *Citranges*.

Similar groups of valuable intermediate types of fruits have been produced by Wm. Saunders, until recently the Director of the Canadian Experimental Farms, by crossing varieties of the ordinary apple, such as the Pewaukee and Wealthy, with a very hardy cold-resistant crab (*Pyrus baccata*). Saunders has produced already numerous hardy intermediate types which bid fair to be of very great economic value, particularly in the cold regions of Manitoba and Saskatchewan (Fig. 648). Second generation seedlings of these valuable types may be expected to yield still more important improvements.

The reproduction of such unfixed hybrids may be said to form the basis of fruit-culture, as all of the apple, peach, pear, plum, orange, lemon and grape varieties, as well as the varieties of small fruits, are of mixed parentage and do not reproduce true to seed. Most of the varieties of these fruits are either known to be hybrids or are superior seedlings that have been selected and propagated. These latter, doubtless, in the

648. *Pyrus baccata* above, and three named crosses with forms of *P. Malus*.—Alberta, Columbia and Robin respectively from top to bottom. ( $\times \frac{3}{4}$ )

greater number of cases were of hybrid nature as all of these fruits are normally cross-fertilized and natural hybridization is exceedingly common.

The same may be said of most flowers, such as carnations and roses, that are cultivated extensively for the cut-flower trade. Practically all of the varieties are unfixed hybrids.

#### The selection of bud-variations.

No consideration of the methods of plant-breeding would be complete without a mention of the improvements that can be produced by what may be termed the selection of bud-variations.

While, in general, all buds of a plant are practically the same, as is shown by the fact that buds taken from the Baldwin apple almost uniformly produce Baldwin apples, yet there is considerable variation frequently in the product from different buds, and it is evident that bud-variations may be classified like seedling-variations, into fluctuations and mutations or the so-called bud-sports (Fig. 649).

649. Bud sport of *Cupressus* to fastigiate type, with branch of similar fastigiate variety on right.

Hybrid plants also frequently, for some cause, show segregations of characters in different buds similar to the segregations shown in  $F_2$  hybrid seedlings. It would thus seem natural to suppose that these variations could be utilized in producing new varieties much as the similar types of seedling-variations are used.

In violets, for example, the propagation is normally by slips that are developed from different buds. These slips when grown into plants frequently show considerable difference, and B. T. Galloway and P. H. Dorsett, of the national Department of Agriculture, have demonstrated that by the selection of slips from plants which are very productive the yield in the number of flowers to the plant can be increased considerably. In the case of the orange, seedling trees are almost always very thorny, yet certain branches may show a tendency to be more nearly thornless, and by the selection of buds from such branches the thorny character of almost all the standard varieties has been reduced. By the systematic selection of vegetative parts, such as buds, slips, suckers, and the like, in many cases very important improvements could doubtless be secured, and the plant-breeder should have a thorough understanding of this method of improvement. In hybrids of mixed parentage, frequently a bud on one side of a plant will sport, showing different tendencies, and many of our new varieties of roses, chrysanthemums and carnations have been produced by the selection of such bud-sports. Many standard varieties of carnations have produced bud-variations that have proved valuable; the Lawson has given rise to the Red Lawson and White Lawson; the Enchantress has produced the Pink Enchantress and White Enchantress. The practice of exercising care in choice of chrysanthemum or carnation cuttings and of

cions for fruit trees is, therefore, seen to rest on rational reasons.

Variations in the character of the seed from different bolls, in the case of hybrid cottons, are frequently found and may be of value to the breeder even in cotton that is propagated by seed. In the study of cotton, similar bud-variations have been found, showing in the lint characters of hybrids. In a number of instances, certain bolls have been found which produced much longer lint than other bolls on the same plant, and similar variations in strength and uniformity of length have been observed. Experiments indicate that such variations, which are doubtless to be classed as bud-variations, are inherited in considerable degree. This being the case even in seed-propagated plants, it becomes desirable to observe and search for bud-variations.

The importance of bud-selection in oranges and lemons has recently been called to attention by the investigations of A. D. Shamel, of the United States Department of Agriculture. It has been found that groves planted with the Bahia or Washington Navel, which is grown extensively in California, frequently show a number of different types with reference to productiveness and form of fruit and that these conditions remain the same from year to year. The same has been found to be the case also in lemon groves, several distinct types not infrequently being produced on the same tree (Fig. 650). These barren trees, and trees producing poor fruit, greatly reduce the production of the grove and in many cases are a serious handicap. Evidence has been collected showing that when buds are taken from productive trees of good type they may ordinarily be expected to produce good types.

In experiments which have been conducted during the last six years in the selection of potatoes, it has been clearly demonstrated that, in a family of potatoes developed from a single tuber and thus positively known to be pure, low- and high-yielding strains can be produced by selecting from low- and high-yielding hills (Fig. 651). Such low- and high-yielding strains have now maintained themselves for three years in over thirty different cases representing work with eighteen different varieties.

The importance of bud-selection is only beginning to be realized and further data is necessary before it can be determined how important this is in different cases. The evidence now at hand, however, clearly indicates that this method of improving plants should be given careful consideration.

H. J. WEBBER.

**BREVOÛRTIA** (J. Carson Breevoort, naturalist, Regent N. Y. State University). *Liliaceæ*. Differs from *Brodiaea* in the long-tubular and 6-saccate corolla: stamens 3, with 3 broad and truncate staminodia: caps. stalked.—One species.

650. Two types of fruit, good and poor, borne on same tree of the Eureka lemon.

**Ida-Mäia**, Wood (*B. coccinea*, Wats. *Brodiaea coccinea*, Gray). **FLORAL FIRE-CRACKER**. Lvs. slender, grassy: scapes slender, 1-3 ft. high, with 3-6 pendulous tubular-saccate fls. 1-2 in. long, which are brilliant crimson-red, tipped with pea-green. N. Calif. to Ore. in wooded foothills. B.M. 5857. G.C. III. 20:687. Gn. 46, p. 503.—The fls. are very lasting and beautiful.

Half-hardy. Needs partial shade and a deep, loose soil, thoroughly drained, and with some leaf-mold. Corm the size of a nutmeg.

CARL PURDY.

**BREWÈRIA** (Samuel Brewer was an English botanist of 18th century). *Convolvulacæ*. Perennial herbs, rarely somewhat woody: fls. much like those of *Convolvulus* but the styles distinct or partly so, the corolla

651. Low- and high-yielding strains of Rural New Yorker potato developed by hill-selection within the progeny of a single tuber.

pubescent outside in the bud: lvs. simple, entire.—Trailing plants of 30 or more species in warm climates.

**grandiflora**, Gray. Root tuberous: st. pubescent: lvs. broad-ovate or oblong-ovate and very short-stalked: peduncles 1-fl'd.; fl. very large (3 in. long), bright blue and showy, funnel-shaped: caps. large and globose-ovoid or ovoid. Fla.—Intro. by Reasoner Bros. One species of *Breweria* (*B. Pickeringii*, Gray) occurs from N. J. and Ill. south, and a few other species are also native farther south in the U. S.

N. TAYLOR.†

**BREYNIA** (for J. P. Breyn, a German botanist of 17th century). *Euphorbiacæ*. Tropical shrubs or trees, rarely cult. Lvs. alternate, simple: fls. small, in short axillary clusters, monœcious, apetalous; calyx imbricate; styles 2-parted: fr. a red berry. Related to *Phyllanthus*: about 15 species in Trop. Asia and Pacific Isls. *B. turbinata* (*Phyllanthus turbinatus*, Sims). B.M. 1862. L.B.C. 8:731, may be the same as *Andrachne fruticosa*.

J. B. S. NORION.

**BRICKÉLLIA** (Dr. John Brickell, an early American naturalist). *Coleosanthus*, Cass. *Compositæ*. About 40 species of herbs or small shrubs in the warmer parts of the U. S. and Mex., only one of which seems to be in the trade. Somewhat allied to *Eupatorium*, from which it differs in having 10-ribbed achenes. Lvs. veiny, either opposite or alternate: fls. white, cream-colored or flesh-colored, small, with pappus either scale-like or somewhat plumose, involucre bracts striate-nerved: achenes striate. Prop. by cuttings under a bell-jar.

**grandiflora**, Nutt. TASSEL FLOWER. Nearly glabrous, 2-3 ft., branchy above: lvs. triangular-cordate or triangular-lanceolate above, coarsely toothed: heads about 40-fl'd., drooping, in large panicles, tassel-shaped and yellowish white. Rocky Mts.—Recommended for moist shady borders, and best grown in a mixture of leaf-mold, loam and sand.

N. TAYLOR.†

**BRIDAL WREATH:** *Spiræa prunifolia*.

**BRIER.** In America, commonly applied to brambles or thorny plants of the genus *Rubus*, especially blackberries. In the Old World, it is applied to large wild-growing roses.

**BRITISH NORTH AMERICA, Horticulture in.** The vast territory of British North America, as understood in this article, comprises the Colony of Newfoundland and the Dominion of Canada. Much of the territory is so little developed horticulturally, and most of the provinces are so very large, that rather extended attention is given here to the adaptabilities of the different political divisions. The map (Fig. 652, page 560) shows the outlines of the territory under consideration, and its relation to the northernmost part of the U. S.

Horticulture in Newfoundland has so far not developed to a great extent and the island is not thought of as a horticultural region; but the colony has great possibilities in this direction. The winter temperatures are not so low as in some parts of Canada where apple trees grow well; and with care and protection from wind the hardiest summer and autumn varieties can be grown. The Canada plum (*Prunus nigra*) is a native of the southern part of the island and no doubt good varieties of this could be produced. The European or domestic plums can also be grown successfully near the coast where protected from the high winds, but owing to the moist air they are very liable to become covered with moss and lichens. Bush-fruits thrive, and strawberries and gooseberries succeed particularly well, and English varieties of both these fruits, which do so poorly in Canada on account of the hot, dry summers, are giving admirable results. In winter the plants are well protected by a deep covering of snow. The hardier vegetables flourish, and large quantities of potatoes are grown by the settlers.

Owing to the relatively moist summer, annuals and herbaceous perennials do particularly well, it being possible to have almost or quite as beautiful a garden there as in eastern Canada.

In the Dominion of Canada, horticulture has become one of the most important industries. In fruit-growing, in floriculture, in vegetable-culture and in the beautifying of cities, towns, and private grounds, Canadians are fully alive to the possibilities of their country; and the rapid development of horticulture in all its branches is an indication of the success that has attended those engaged in its pursuits.

The history of horticulture in Canada dates from the early settlement at Annapolis Royal in Acadia, now Nova Scotia, in 1605, and from the founding of the city of Quebec, now in the province of Quebec, in 1608. There is a definite statement as early as 1663 that apple trees were growing near the banks of some of the rivers in Acadia. There are also records of trees growing in the province of Quebec about that time. In the province of Ontario, it was about the beginning of the eighteenth century before horticulture began appreciably to develop, while in British Columbia, which has made such rapid advances in recent years, fruit trees were not planted until about the middle of the nineteenth century. Owing to inadequate means of transportation, the development of fruit-culture was not rapid in any part of Canada until within the past half-century, but now the extension of orchards, small fruit-plantations, glasshouses, and truck-farms is very marked every year.

The census of Canada for 1911 gives the following figures: Total number of fruit trees in Canada, 20,812, 556; area occupied by fruit trees in Canada, 376,322 acres; estimated capital value of fruit trees in Canada, \$127,000,000. The quantity of fruit grown in Canada is not known, but the Trade and Navigation Returns for the year ending March 31, 1912, show the exports of fruit from all ports to be:

	Value
Dried apples, 3,149,620 pounds....	\$248,035
Fresh apples, 1,664,165 barrels....	5,104,107
Berries.....	106,486
All other fruits.....	159,293
Canned and preserved fruits.....	257,590

652. British North America, showing Newfoundland, the nine Canadian provinces, and the vast territory beyond.

The larger proportion of this fruit is produced in the provinces of Ontario and Nova Scotia, but rapidly increasing quantities are grown in British Columbia.

The fruit areas of Canada are large enough to supply Canada and a large part of the world with some kinds of fruit, and particularly with the apple, for many years to come. In the great province of Ontario, 220,000 square miles in area, larger than the states of New York, Ohio, Illinois and Michigan together, there are large districts in which apples, pears, peaches, plums, cherries, grapes and the small fruits can be grown to perfection. The province of Quebec is considerably larger than Ontario, and while the tender fruits do not succeed except in the most favored parts, apples are grown in large quantities yearly. From east to west in the provinces of Quebec and Ontario there is a belt of about 700 miles in length in which apples and other hardy fruits can be grown; while in the province of Ontario alone the best winter apples, pears, and plums can be grown successfully over an area about 350 miles long and 30 to 150 miles in width. The successful cultivation of peaches in Ontario is confined to the Niagara district and to points along Lake Erie and Lake Huron, but the area suitable for this fruit is extensive enough to supply a large population.

Nova Scotia has long been noted for its apples. The most favored districts are the Annapolis and Cornwallis valleys, where apples, pears, plums and cherries can be grown and where even peaches can be successfully raised. These valleys have a total length of about 100 miles and vary in width from 6 to 11 miles. Fruit-culture is not confined to this district, as over most of the province the harder fruits can be grown successfully. New Brunswick has not yet developed a fruit industry to any great extent, but in some of the valleys apples and other hardy fruits of the finest appearance and best quality can be produced. In recent years there has been a marked awakening in this province and, owing to the cheapness of land and the beauty and quality of the fruits that can be produced, there would seem to be a good future for horticulture.

Prince Edward Island, the smallest province of the Dominion, produces excellent tree fruits, and, owing to the late season, the apples keep better than in any other part of the Dominion. Means of transportation are not yet good, but it is hoped that this will soon be much improved.

British Columbia, the area of which is about 370,000 square miles, or more than twice the size of California, has large sections admirably adapted to fruits. Like the states of Oregon and Washington, with which its natural conditions may be compared, British Columbia has a number of districts with special conditions. Three of these are, (1) that in the damp coast climate of Vancouver Island and the Lower Mainland; (2) in the dry interior country where irrigation is, as a rule, necessary; (3) in the Kootenays, east and west, where irrigation is necessary only in places. In these districts all the best fruits, including peaches in some places, can be grown to great advantage. There are, however, many valleys that are being found suitable for fruit-culture, varying much in climate and extending from the American boundary far north.

British Columbia is expending its efforts mainly to supplying the prairie provinces of Canada; and it has been very successful in placing fruits on these markets in good condition. The trade abroad is growing also. Ontario is a close competitor of British Columbia for the prairie trade, but the increase in population is so rapid that it will require both provinces to supply the demands for a long time to come.

The prairie provinces of Manitoba, Saskatchewan and Alberta and the great territories to the north pro-

duce excellent bush fruits, but the tree fruits have for the most part not done well up to the present, although the hardiest varieties of apples succeed in some of the more favored localities and plums are native to Manitoba and the early varieties can be grown successfully over a wide area.

Some of the influences affecting Canadian horticulture may be mentioned. The Dominion Experimental Farms, now sixteen in number, work upon which was begun twenty-five years ago, have played an important part. There are six Provincial Agricultural Colleges, all of which have Experiment Stations that disseminate information both through the students and by literature. The Provincial Experiment Stations and demonstration orchards are also doing much to explain the possibilities of fruit-culture in their several districts. Seven Provincial Fruit Growers' Associations lend their aid in spreading a knowledge of the best methods of fruit-culture and of uniting the growers in coöperation and legislation. The horticultural periodical literature of Canada, although represented by few papers, has done much to aid fruit-, flower- and vegetable-growers.

The Farmers' Institute and orchard meetings organized by the Provincial Governments and assisted by the Dominion Government, are very practical and helpful. In the province of Ontario, a large proportion of the

653. The fruit regions in eastern Canada.

counties have the District Representative, a Government official whose duty it is to instruct the people by word, by experiment and by demonstration.

The horticultural societies assisted by the Provincial Government, of which there are seventy-five in Ontario, are doing excellent work in awakening a greater interest in horticulture and in spreading information, especially in regard to ornamental plants.

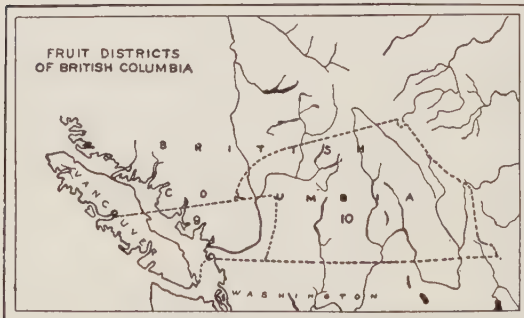

The apples originated by Wm. Saunders in crossing the wild Siberian crab-apple, *Pyrus baccata*, and the varieties of the apple, have enabled the settlers in the prairie provinces to grow at least small apples where larger ones do not succeed; and the larger-fruited varieties obtained by Saunders, by introducing more of the blood of the apple into the first crosses, are now being tested for hardiness, and, if found worthy, will mark a step in advance.

All these factors affecting horticultural conditions and progress have been made still more effective by the coöperative movement that has in recent years made much progress in Canada. In the provinces of Ontario and Nova Scotia are many coöperative associations that now have central organizations where plans affecting the welfare of all the associations are discussed. These associations are doing much to make the fruit marketed of more uniform character and to bring better returns to the producer. One of the best influences in the improvement of horticultural products in Canada is the Fruit Marks Act (now the Inspection and Sales Act) passed in 1901, and operative over the whole of Canada. By this Act, growers are compelled to pack

their fruit according to certain standards and are liable to fine if they do not do so. Inspectors are stationed at packing-houses, on the markets, and at the ports of export, who examine the fruit to determine whether it is packed according to law. A marked improvement has been noticed in the Canadian fruit exported since this law went into effect. There are also standard barrels, boxes and baskets for the whole of Canada.

While floriculture is growing very rapidly, the area under glass in Canada is not very large yet, it being estimated at about 120 acres or 6,000,000 square feet in 1912. The estimated capital invested is \$1,500,000 and the value of the output \$1,800,000. The flowers most grown under glass in Canada are carnations and roses, although many other kinds are also raised. Some of the Canadian growers have an international reputation for the quality of the flowers they produce. The official organ of the florists in Canada is "The Canadian Florist," a trade paper published every two weeks.

Many kinds of vegetables succeed admirably in Canada and there are a large number of skillful growers. Owing to the rapid development of the larger cities and the many new towns in the newly settled parts, there are many openings for market-gardeners. Large quantities of vegetables, including particularly tomatoes and corn, are grown for the canning factories in southwestern Ontario where the season is earlier than in any other part of eastern Canada. Early vegetables are

654. The fruit region (within dotted lines) in British Columbia.

grown on a large scale, and have proved very profitable to those engaged in the business. Perhaps the most noted vegetable grown in Canada is the Montreal muskmelon, which is well known for its high quality in many cities of the United States. The production of such a high-class melon is a good indication of the summer climate of Canada, which in many parts is hot enough to mature melons well. The market-gardeners are represented in Ontario by the Provincial Vegetable Growers' Association, branches of which are to be found in a number of the cities and towns. This organization has done much to assist market-gardeners and to make them feel that their calling is as important as any other branch of agriculture. W. T. MACOUN.

#### Nova Scotia.

Nova Scotia (Fig. 655) is a peninsula on the extreme eastern side of Canada. It extends in a northeasterly and southwesterly direction and is crossed by the forty-fifth parallel of north latitude. No part of the interior is more than 30 miles from the sea. The surface is gently undulating, with no high mountain ranges. The principal farming and fruit-growing sections are mainly in the valleys through which the rivers run and around the headwaters of the Bay of Fundy, where the high tides have left extensive deposits of rich alluvial soil. The annual rainfall is about 42 inches.

The French Acadians early made plantings of the apple in this province. When the New England settlers

came, in 1761, to occupy the lands of the deported French, they found apple trees in bearing, many of which lived and continued to bear fruit well along into the last century. The leading horticultural industry is fruit-growing. Its most important division is apple-culture, although pears, plums, cherries and small fruits are successfully grown. These soft fruits are necessarily sold in the local markets, which, though steadily growing in size, are as yet of too limited capacity to justify an extensive development of the culture of such perishable products. Apples, on the other hand, are shipped to the British and other foreign markets where, in their season, they successfully compete with those from other parts of the northern hemisphere.

The strictly horticultural region of Nova Scotia is a small section of the western part of the province generally called the Annapolis Valley. This region, except in its extreme eastern part, is separated from the Bay of Fundy and protected from the direct force of the northerly and westerly winds by a range of hills, some 400 to 500 feet in height, known as the North Mountain. It includes the valley of the Annapolis River, which flows southwesterly to the Annapolis Basin, and the valleys of the Pereaux, Habitant, Canard, Cornwallis, Gaspereau and Avon Rivers, which flow into Minas Basin on the east. It is a narrow strip of country 6 to 10 miles wide and less than 100 miles long.

Here apple-culture, from being a side line to general farming down to about forty years ago, has grown to be the leading branch of agriculture. The yield of apples in this district, packed and sold in 1911, was 1,734,000 barrels. The yield for 1912 is estimated at 1,100,000 barrels. These figures do not include, in either case, those that were used by the canneries, evaporators and vinegar factories, or that were consumed in the district in which grown. About one-tenth of the output finds a market in the towns and the villages of the non-fruit-growing sections of the maritime provinces, the remainder being exported to Great Britain, Germany and other European countries, and to Newfoundland, the Canadian West, the West Indies and South Africa. The varieties of apples grown have been selected chiefly with reference to the English market. The leading commercial sorts are Gravenstein, Blenheim, Ribston, King, Yellow Bellflower, Cox Orange, Wagener, Baldwin, Stark, Spy, Golden Russet, Fallawater, Roxbury Russet and Ben Davis. Some of these have long been known in England and were introduced from that country. The Gravenstein, especially, reaches a high quality here. The winter varieties also do well and mature just as the cool weather of autumn comes on.

As a rule, orchards are carefully cultivated, fertilized, pruned and sprayed. A large quantity of commercial fertilizer is used every year, as the area in orchards has outgrown the supply of stable manure. Cover-crops are grown to furnish humus, the clovers, vetches and buckwheat being the crops chiefly used for this purpose. The practice of thinning apples has lately been adopted by many of the best growers and is likely to become more general as competition in fruit-raising increases.

A system of frost-proof apple warehouses, that has come into existence during the last sixteen years, is an important element in the carrying-on of the fruit business in Nova Scotia. These—numbering one hundred in all—are found at the railway stations throughout the fruit district. The usual width is about 40 feet, the length from 80 to 120 feet, affording room for packing and storage for 5,000 to 10,000 barrels. Formerly, the fruit-grower packed his apples at home, or in his barn. Then, when a steamer was ready to load at Halifax, the apples had to be hauled to the railroad station, often several miles distant, and loaded into the waiting cars. Now the apples are generally taken in barrels directly from the orchard to the warehouse where they are stored until ready to be packed out for shipment.

XVIII. Canadian orchard development.—The tidewater country in Nova Scotia.

Under this system, it is possible with very little delay to pack and place on cars a steamer-load of apples. A railway haul of four or five hours brings the cars to the side of the steamer so that the danger from frost, even in zero weather, is largely avoided.

A further advance was made in the business of packing and marketing apples when coöperative fruit companies were formed. The first company of this kind was organized in Berwick in 1907. During the next five years, more than thirty similar companies were formed. Under provincial legislation enacted in 1912, these were organized into a central association known as the United Fruit Companies of Nova Scotia, Limited. All the apples of the companies affiliated in this central association are sold through its agency. It controls the sale of fully one-half of the apple crop of the province. A uniform standard of grading is maintained, an official of the central association inspecting the packing in all the warehouses of the affiliated companies. Coöperation in the marketing of apples was quickly followed by the coöperative manufacture of barrels and purchase of fertilizers, feeds and seeds, greatly to the convenience and financial advantage of the members of the companies. In the near future, all farmers' supplies will probably be purchased coöperatively.

The establishment of evaporators, canneries and vinegar factories throughout the fruit district, some of them owned by coöperative companies, furnishes a market for defective fruit and has also the effect of improving the grade of apples packed. There are now eight evaporators, two canneries and four vinegar factories in operation.

Local nurseries, chiefly for the propagation of apple trees, are to be found at Annapolis, Berwick, Waterville and Wolfville. While these have received good patronage in the past, the larger quantity of nursery stock in recent years has been imported, chiefly from Ontario. With a view to avoiding the danger of introducing noxious insects and plant diseases, the provincial department of agriculture has lately passed strict regulations governing the importation of nursery stock. The effect of this has been to stimulate the home nursery industry.

Pears, plums and cherries are grown for home use and the local markets. Bartlett and Clapp Favorite are the varieties of pears most largely grown. Moore Arctic, Lombard, Yellow Egg, the Gages, Damsons and Burbank are the chief plums. The cherries are the Morello and other varieties of the sour type. Peaches are grown to some extent in the western part of the province, Alexander, Early Canada and Fitzgerald proving hardy.

Cranberries constitute an important part of the fruit crop of Nova Scotia. They are grown on reclaimed bog lands that would be unsuitable for any other farm crop. There is much land of this kind in the province still unused. In 1908, the cranberry crop in the vicinity of one railway station, Auburn, amounted to nearly 5,000 barrels and netted the growers \$25,000. A good market for Nova Scotia berries is found in Montreal and the Canadian West.

Truck-gardening is conducted to some extent on the light sandy soil of the central part of the Annapolis Valley. In the vicinity of Berwick, Aylesford, and Kingston, such crops as strawberries, raspberries, tomatoes, green beans, asparagus and rhubarb, are grown for the local markets. Some of the tomatoes go to the cannery.

Only one important variety of apple originated in Nova Scotia, the Banks Red, a bud-sport of the Gravenstein. John Burbidge, who settled in the Cornwallis Valley in 1764 introduced the Nonpareil (Roxbury Russet). Charles Inglis, first Bishop of Nova Scotia, who received a grant of land in Aylesford Township, in 1790, introduced the Yellow Bellflower, which

thence came to be known here as Bishop Pippin. Charles R. Prescott introduced Ribston in 1814, Blenheim in 1829, Gravenstein and Alexander in 1835, Baldwin and Greening in 1820 and Northern Spy shortly after 1852.

The Nova Scotia Fruit-Growers' Association, founded in 1863, is the oldest in the Dominion, and receives an annual grant from the provincial government. For several years it assisted in maintaining a school of horticulture at Wolfville. In 1905, this school was merged into the College of Agriculture at Truro.

In 1911, a fruit experiment station was established at Kentville. This is maintained by the federal government at Ottawa. The provincial government has established thirty-five demonstration orchards in parts of the province outside the fruit district proper. The purpose of these orchards is to discover the fruit-growing possibilities of the different sections of the province, to find out the varieties best suited to these sections, and to give a demonstration of what orchard practice is considered most effective in such localities. Horticulture is taught at the Agricultural College which was established at Truro in 1905.

PERCY J. SHAW.

655. Nova Scotia, showing the present fruit district and two centers (Bridgewater and Brookfield), where the industry is beginning to develop.

#### Prince Edward Island.

In the Gulf of St. Lawrence, and separated from the continent by the Northumberland Strait, lies the province of Prince Edward Island (Fig. 656), the "low and beautiful land" that Cartier saw on the afternoon of June 30, 1534. It is situated between  $46^{\circ}$  and  $47^{\circ} 7'$  north latitude and east of  $64^{\circ} 27'$  west longitude, and is distant from New Brunswick 9 miles, from Nova Scotia 15 miles and from Cape Breton 30 miles. In form, it is an irregular crescent, concaved toward the north with such an exceedingly indented coastline that no part of the country is far distant from the sea. Sand-dunes extend along the north shore for a distance of 50 miles. The surface is gently undulating. Ranges of low hills traverse the island from New London to Hampton, from Brooklyn to Wood Islands, and from Red Point to Rollo Bay. The highest elevation is less than 300 feet. Small flat areas occur in the western part of Prince Co.

The climate is temperate and not subject to rapid changes. For the past five years, the average temperature during the winter months was  $36.6^{\circ}$ , the lowest registered being  $-19.5^{\circ}$ , and during the summer months  $70^{\circ}$ , with  $86.5^{\circ}$  the highest. The yearly precipitation varies from 38 to 42 inches, a little less than half falling during the months May to October in light showers at more or less regular intervals.

The whole population is engaged in agriculture and fishing and in the merchandise connected therewith. Horticulture is yet in its infancy and only very few of the inhabitants have begun to realize its possibilities.

Nearly every farmer has a few trees producing sufficient apples for his own family. But few have seriously

656. Prince Edward Island. The shaded parts are horticultural sections.

considered apple-growing as a revenue-producing branch of agriculture. The first trees were planted shortly after the English occupation in 1763. The stock was brought out from the Old Country and was nearly all of the cider varieties. On this account it was generally believed that good apples could not be grown in this province. For over a century very little improvement was made.

The development of the apple industry in Nova Scotia stimulated the planting of more trees in Prince Edward Island and led to the setting out of nurseries in 1886 by William Taylor at Lower Freetown and by Condon at Kensington. They received a great many orders for trees but the orders were so small (very few people wanting more than half a dozen) that there was not much profit in the business and it was not continued.

A few men, however, were enthusiastic over the possibilities of fruit-growing and at the call of Lieutenant-Governor Howlan met in Charlottetown on March 30, 1896, and formed the Fruit-Growers' Association of Prince Edward Island. It received the encouragement of the Department of Agriculture and was given an annual grant of \$100, for the purpose of holding a fruit show.

This again gave a further stimulus to tree-planting, and nurseries were set out by D. A. Sharp at Summerside, Thomas Moyses at Central Bedeque and John Robertson at New Perth. Many trees were sold but the business does not seem to have been very profitable, and at the present time all the stock is imported. A few men, however, set out commercial orchards and between the years 1897 to 1900 some shipments of apples were made to the British market. It was very difficult, however, to find more than a few barrels of one variety in a district. This added very much to the expense of packing and shipping, and as the business was at best very uncertain, it was soon given up.

In 1909 the Coöperative Fruit Company was formed. The purpose was to provide proper packages and to get together sufficient quantities of apples of one variety to make a profitable shipment. The Department of Agriculture provides the Company with a secretary and makes a small annual grant, sufficient to cover truckage expenses.

In 1909, eighty-four barrels were shipped; in 1910, some 350 barrels. The expenses of getting their apples together, graded, properly packed and marketed were too great and in 1911 each grower shipped his own. This, however, proved even less satisfactory and the Company is preparing to pack again this autumn. They hope, however, to get a number of barrels of apples together at certain centers, and with this end in view, all the orchards in these vicinities are being sprayed.

For a number of years the question of varieties has been taken up by the Fruit-Growers' Association. The following are now recommended: For home orchard—Yellow Transparent, Crimson Beauty, Duchess of Oldenburg, Wealthy, Wagener, King, Northern Spy, McIntosh Red, and Stark. For commercial orchard—

Wealthy, Alexander or Wolf River, McIntosh Red, Ribston Pippin and Ben Davis.

The feeling is general that the next few years will witness a great development of the apple industry in Prince Edward Island.

Very few pear trees have been planted, but when given good cultivation and properly sprayed, they have done well. The most popular varieties are Clapp Favorite, Bartlett, Vermont Beauty, Flemish Beauty, Howell and Anjou.

The cool, moist climate of Prince Edward Island favors the growing of plums of the very finest quality, and of late years quite a number of trees have been set out. Among the varieties best suited to Island conditions are Glass Seedling, Moore Arctic, Quackenboss, Yellow Egg, Victoria, Bradshaw, Prince Englebert and Blue Damson.

Cherry trees were introduced by the early French settlers and, as they were able to take care of themselves, met with great success. Nearly every farmstead has a few trees. The crop is, however, very uncertain, as a late frost catches the blossoms about every third year. They are nearly all sour cherries of the Richmond and Montmorency varieties. In a few orchards sweet cherries are being tried with indifferent success. They bloom too early and are caught by the frost.

Grass lands that have not been manured with mussel mud invariably grow a crop of strawberries in every part of the province. The increased cost of labor has made the picking of the wild ones unprofitable and for the last few years the cultivated varieties have taken their place on the market. From 8,000 to 10,000 boxes to the acre is considered an average crop. Some progressive farmers have had very large returns from strawberry-growing, with the result that prospects are very bright for a large industry. The chief varieties grown at the present time are Splendid, Glen Mary, Senator Dunlap, Williams and Wilson.

Among the bush fruits, raspberries and blackberries are being cultivated but not to the same extent as gooseberries and currants, which are in greater demand. All, however, are being grown very successfully. Dewberries are not grown to any extent. They have been introduced at the Experimental Farm and their cultivation will likely be extended.

As wild strawberries are found in the higher grasslands, wild cranberries are found in the bog-lands and marshes. In a few districts they are being cultivated and giving very large returns. When the plantation can be flooded, the crop is fairly sure, but when it cannot be flooded the frost frequently does much damage. The average crop is about eighty bushels to the acre.

There are several thousand acres of blueberry barrens in the province, from which about twenty carloads of berries are shipped annually. They do not, however, seem to improve by cultivation and the increasing cost of labor will likely lessen the amount marketed. Now and again the crop is a comparative failure, due to frost or to severe drought.

Prince Edward Island is peculiarly adapted to the growing of fruit. The reason that more progress has not been made is the inadequate transportation facilities. Last year, however, arrangements were made for three calls of an ocean steamship at Charlottetown on the way from Montreal to Manchester. The car ferry, also, that is about to be built between Carleton and Cape Tormentine will further help to overcome this difficulty, and it is expected that the next few years will witness a great development in horticulture in this

province. The census returns for 1911 give the following figures of the industry:

	No.	Product
Apple trees .....	205,979	160,124 bushels
Peach trees .....	546	13 bushels
Pear trees .....	2,439	773 bushels
Plum trees .....	20,625	27,480 bushels
Cherry trees .....	53,094	7,576 bushels
Other fruit trees .	9,998	1,479 bushels
Grapes .....		1,641 pounds
Strawberries .....		186,692 boxes
Currants and gooseberries .....		48,429 quarts
Other small fruits .....		1,860 boxes

THEODORE ROSS.

#### New Brunswick.

The province of New Brunswick (Fig. 657) lies mainly between 45° and 48° north latitude, and 64° and 68° west longitude. Its boundaries are: On the south the Bay of Fundy, on the east the Strait of Northumberland and the Gulf of St. Lawrence, on the north the Bay of Chaleur and the province of Quebec, on the west the state of Maine. The greatest length of the province from north to south is 230 miles, and its greatest breadth is 190 miles. It has an area of 27,985 square miles and about 600 miles of seacoast. It is a rolling country of no great elevations with the more hilly sections formed by an extension of the Appalachian Mountains in the northern and northwestern parts of the province. Few countries are so well watered as New Brunswick. Lakes and small streams are numerous all over the country. The St. John River, which flows into the Bay of Fundy, is 450 miles long. The Miramichi and Restigouche Rivers, both of which are over 200 miles long, drain into the Gulf of St. Lawrence. The Petitcodiac and St. Croix are important rivers situated respectively in the eastern and western ends of the province and flowing into the Bay of Fundy. The yearly record for continuous sunshine is excelled by only one other province in the Dominion. The average hours of sunshine recorded yearly at Fredericton is 1,983. The average annual precipitation for the last thirty-eight years at Fredericton is 45.6 inches.

The province contains 17,393,000 acres, of which 7,750,000 are Crown land, 5,000,000 acres are settlement land and 4,643,000 acres are private timber land. According to the report of the Agricultural Commission, which investigated farming conditions all over the province in 1908, there were at that time 32,480 farms, and 1,474,076 acres of cleared land.

Potato-growing is the leading horticultural industry. The province is particularly adapted for the production of this crop, as the comparatively cool moist climate enables the potatoes to grow for a long period of time, and they are green and vigorous until the frost comes, hence their firmness, full starch content, good keeping quality and pleasant flavor. An additional advantage is the ease and cheapness with which the potato can be shipped to tide-water, since the St. John River and its tributaries water an area of 2,000 square miles. Carried in scows, potatoes are delivered in St. John from York County for 5 cents the barrel. Carleton County on the western border, watered by the upper reaches of the St. John River, has long been the banner county for potato-growing. In 1910, it had 8,786 acres under cultivation, with a production of 1,127,680 bushels, or 128.3 bushels to the acre. In 1909, from 8,940 acres, it derived 1,800,676 bushels, or 201.4 bushels to the acre. The same year the province averaged 187.4 bushels to the acre. Victoria County, to the north of Carleton County and immediately adjoining Aroostook

County, Maine, affords considerable excellent potato-raising land. In fact, the entire valley of the St. John River is well suited for this purpose and potatoes are also grown extensively in the eastern counties of Kent and Westmoreland.

The entire acreage under potatoes in the province in 1910 was 47,744 and the yield 6,067,276 bushels. In 1909 it was 47,853 acres and the yield was nearly 9,000,000 bushels. In 1911, the acreage was 47,304 and the yield 8,493,212 bushels. Large quantities of potatoes are now being shipped annually to Ontario, the West Indies and Cuba. Experiments conducted during the past few years by experimental stations and practical farmers in Ontario show that potatoes produced in the maritime provinces gave a much larger yield than those from Ontario-grown seed. This has led to an increasing demand from Ontario for New Brunswick potatoes for seed purposes.

Apples were undoubtedly grown in the province in the early part of the nineteenth century, but it remained for Francis Peabody Sharp, New Brunswick's pioneer horticulturist, to demonstrate the possibilities of commercial apple-growing in this northern climate. His operations were conducted at Upper Woodstock on the St. John River, and there, in 1844, he set out his first trees. Sharp planted many large orchards, did extensive work in hybridizing and introduced many of the standard varieties into New Brunswick from the United States and elsewhere. His death occurred at Upper Woodstock in December, 1903. From that time an impression that apple-growing could not be made a success seemed to gain ground, but of late years this has been swept away and the outlook for the future of the industry is now very bright.

The list of apples recommended for New Brunswick covers the season and provides a class well suited for export shipment, as well as for supplying the local markets. With cheap and rapid transportation by water, with an over-seas market close at hand, with plenty of suitable land at a moderate cost, with the knowledge that has been secured as to the proper varieties to plant, and with the active coöperation of the government, the success of New Brunswick as a fruit-producing area seems assured.

Many commercial orchards are now being planted, chiefly in the St. John River valley and in the eastern part of the province, and apple-growing bids fair in the near future to take first place in the horticultural crops of the province. The provincial Department of Agriculture established a horticultural division in 1910 and there are now a provincial horticulturist and three assistants actively engaged in promoting the fruit-growing industry. Preparations for an export trade are being made by experimental shipments of apples

657. New Brunswick. The shaded parts represent the chief fruit-growing and horticultural areas of the province.

to the European markets and the placing of exhibits in the principal cities of the United Kingdom and Canada. The following varieties of apples are grown very successfully: Crimson Beauty, Red Astrachan, Duchess, Sharp New Brunswick, Yellow Transparent, Wealthy, Dudley, Alexander, Wolf River, Fameuse, McIntosh Red, Bishop Pippin, Golden Russet and Bethel. Northern Spy, King of Tompkins and Rhode Island Greening are grown to a limited extent. The Moore Arctic, Lombard and Yellow Egg plums and Flemish Beauty and Clapp's Favorite pears are grown successfully.

Wild raspberries, strawberries, blueberries and cranberries grow in abundance. Strawberry-culture was first introduced into New Brunswick at Kingston, Kings County, about 1862, by the late D. P. Wetmore, Inspector of Schools. Large quantities are now produced, and as the season of maturity is comparatively late, many shipments are made to Boston and Montreal, where they are much in demand, as the strawberry crop is then finished in other sections. Blueberries grow wild in enormous profusion and are canned in large quantities.

Truck-gardening is practised extensively on the

but in the extreme north arctic conditions prevail and the country is sparsely inhabited. The greater part of the province, however, is well suited to agriculture, and the returns per acre compare favorably with other agricultural areas of Canada. The rainfall, although quite scanty at certain seasons, is usually sufficient. Irrigation is seldom or never practised and is usually unnecessary.

When horticulture began in Quebec is not known, as it is older than the oldest records. When the country was first explored by the French, the Indians knew the melon and cultivated it with some success, as well as a number of other crops of interest to horticulturists. Father Charlevoix (S.J.), the historian, is very plain on this latter point. In a letter dated Chambly, April 1, 1721, while referring to Montreal, he asserts that "The Indians, before our arrival in Canada, were familiar with both ordinary melons and watermelons." He said, "The former are as good as any in France, especially those raised on the island of Montreal, where they grow in rich profusion" (Vol. III, Journ. d'un Voyage, etc., p. 164).

That melons in ordinary seasons were common enough in Montreal may be gleaned from the appended

quotations from a letter of Father Claude Chauchetiere (S.F.), dated Montreal, August 7, 1694: "We have had no melons to speak of this year; we shall barely have enough for seed. This is something I have never yet seen before in Montreal, and every one is surprised at it."

The "Relation par lettres," 1709, attributed to Father Antoine Tiley (S.J.), is authority for the statement, "The savage had the small squash, the watermelon, the gourd and the sunflower before the French came to the country." Although horticulture is old in Quebec, it has never been extensively practised, and the industry is expanding slowly. In the vicinity of Montreal, vegetables are

extensively cultivated for the home market, but the home market is not nearly supplied by native-grown produce and will not be for some time to come.

The present fruit areas are indicated on the map by parallel lines, while those partly in fruit are dotted. The areas in which fruit might be grown are inclosed by a dark line surrounding the section. It will be seen that the total area is not large. Much of the province south of the St. Lawrence possesses great horticultural possibilities and expansion may there be looked for. Rouville, Chateauguay, Hochelaga, Jacques Cartier, Two Mountains, Stanstead, L'Assomption are regarded as fruit counties; Huntingdon, Argenteuil, Vaudeuil, Soulange, La Prairie, Napierville, Kamouraska, L'Islet, Montmagny and Bellechasse are partly in fruit; while Compton, Missisquoi, Brome, Beauce, Shefford, Bagot and counties on the St. Lawrence to Champlain County may be regarded as possible fruit areas, but are not as yet extensively planted.

The present status of horticulture may be gleaned by a study of the census of 1911 so far as the fruit industry is concerned. It would seem that many of the old trees have fallen victims to the ravages of time; but that young trees are being set in larger numbers. Better methods and a more thorough dissemination of knowledge are constantly crowding out the old, so that there

658. Horticultural regions of Old Quebec.

northeastern bank of the St. John River, in the vicinity of Maugerville and Sheffield. The soil there is a dark loam, several feet deep and exceedingly fertile, being the old river-bed, and large quantities of cabbages, cauliflowers, tomatoes, cucumbers, and the like, are grown and shipped to Fredericton and St. John.

A. G. TURNEY.

#### Quebec.

Old Quebec (Fig. 658) occupies a unique position in the Dominion of Canada because it is the oldest province, the largest province and the province in which the English-speaking people are in the great minority. Although not regarded as maritime, yet it possesses considerable coast; and the mighty St. Lawrence takes on the character of an open sea. The St. Lawrence and the numerous rivers and lakes that feed it are the principal physical features of the province, and these features have made of Montreal, Quebec's chief city, the importing, exporting and distributing center of Canada. The Appalachian Mountains extend into Quebec under the name of Notre Dame, but in no place do they reach any great height. The greater part of the country is decidedly level, while some sections are gently undulating.

South of the St. Lawrence the climate is not severe;

is no doubt that a few years hence the number of bearing trees will be much increased. The census figures are as follows:

	1901	1911	Increase or decrease	Per cent of Increase or decrease
Orchard and nursery (acres)	34,289	34,376	Inc. 87	Inc. 0.2
Vineyard (acres)	119	641	Inc. 522	Inc. 438.6

Other small fruits....		194,901		

The nursery business is popular in the province. Considering the size of the horticultural areas, the number of nursery firms doing business is large. Under the name of "northern-grown stock" the sale has been pushed. All nursery produce is carefully inspected by government officials, and all imported stock must be inspected before planting may be made.

Many varieties have originated in Quebec. The most of these are of minor importance, but the Montreal melon and the Fameuse apple have done more to advertise horticulture in Quebec than all other causes combined. The Montreal muskmelon is a melon of great size, often weighing nineteen and a half pounds. There are many cases on record in which they became much heavier, but these exceptionally large ones are not sought after. It has been stated that early French Jesuits brought melon seed to Quebec and that the present Montreal melon evolved from this source, but there is no such record. If this ever happened, the event was deemed of so little importance as to be unworthy of record. There can be no doubt, however, that the Indians were cultivating the melon in Quebec when first explored by the French in 1645 to 1649. Father Bressani (S.F.) mentions a plant he had seen in the country of the Hurons, now Simcoe County, which he says was similar to the melon of India (Bresse Relation, Martin's translation, p. 68). The Journal of a "person of merit," name not given, 1663, who was sent out expressly to report on the resources of Canada, and

who spent one year in the colony, has this to say on the matter in question: "Thence we proceeded up the river to Montreal. Its latitude is that of Bordeaux, its climate most agreeable, its soil excellent; a gardener here has but to cast his melon seeds into a little patch of loosened earth among the stones and they do not fail to thrive without further care on the part of the man" (Relations 1663, quib, ed. p. 28, 2 col.; Chiv. ed., Vol. 48, p. 169). He adds, "Squashes are raised there with still less labor, but differ much from ours [in France] for some have the flavor of apples and pears when cooked." The Montreal melon has not been an equal success in other sections. The peculiar soil-formation and climatic conditions on the island of Montreal combine to give the fruit a flavor which is not equaled elsewhere. At the beginning of the melon season moderate-sized specimens bring on the Montreal market \$18 per dozen and retail at \$2.25 each. The Fameuse apple is now commonly spoken of as the national apple of Quebec. No definite records exist concerning the exact origin of the Fameuse. There can be no doubt, however, that the Fameuse is a seedling arising from seed brought from France by early French priests. The Fameuse in Quebec is a very striking apple; in form, color and flavor it is par excellence. No province to the west can compete with Quebec's Fameuse. Specimens are produced here as nearly ideal as may be found, as comparative exhibitions have shown. Fameuse apples from this province are easy winners.

The local government grants \$12,600 as an aid to horticulture. From this sum \$7 a month is allowed all students from Quebec attending the regular agricultural courses at the colleges; \$1,500 is granted to three pomological societies. Aid is also given to horticultural extension work, such as demonstration trains, demonstration orchards and various forms of institute work. Horticulture is taught in three colleges, Macdonald College, Oka, and St. Anne de la Pocatiere, which deserve special mention. Macdonald College is unique in agricultural development along educational lines. It sprang into being fully equipped and ready for efficient service at once. This was made possible by the munificence of Sir William Macdonald, a public-spirited capitalist of Montreal. It was Macdonald who financed the undertaking; but it was James W. Robertson, a man of great vision, who, by means of lectures, literature and personal persuasion, aroused widespread interest in agriculture; and who, by his work and ideals was able to attract the attention of Sir William and to gain his financial support. The college property comprises 561 acres, and boasts the largest horticultural department in similar institutions in America. The courses run over four years, leading to the degree of B. S. A. The agricultural school conducted by the Trappist fathers is of great interest to visitors. These Trappist monks, by their industry and skill in agriculture, have changed the face of the countryside in the region of the Lake of the Two Mountains since 1880. The scientific and practical training at the college is given by twelve to fifteen fathers and lay teachers. The average number of pupils at present is about one hundred, who come largely from the province of Quebec. Students who have passed all examinations successfully obtain the degree of B. S. A. from Laval University. The agricultural school of St. Anne de la Pocatiere teaches horticulture as well as allied agricultural subjects. A limited number of students are in attendance, who secure diplomas upon completing the courses.

E. M. STRAIGHT.

#### Ontario.

The horticulture of Ontario is undergoing very rapid evolution. The province is so situated geographically and topographically as to enjoy a climate much milder than that of most parts of Canada. Within the prov-

ince, towns and cities are growing very rapidly, and markets are thus being provided for high-class products of all kinds. The Canadian Northwest, also, is rapidly becoming an important market and is attracting every year a large volume of trade that formerly went to Great Britain and western Europe.

Ontario (Fig. 659) includes a vast extent of country, being over 700 miles from extreme north to extreme south and approximately 1,000 miles from east to west. The outline of the province is very irregular. The most noticeable feature is the vast extent of boundary line which borders on the Great Lakes. The altitude of the lakes varies from 250 to about 600 feet and inland Ontario ranges from lake-level to 1,700 or 1,800 feet. Practically all of the fruit-growing districts lie below 1,000 feet and all the important fruit districts border the Great Lakes.

The early settlers paid less attention to horticulture than to other branches of rural activity, but of late years very rapid development has begun, especially in connection with fruit-growing, although commercial vegetable-growing and commercial floriculture are becoming increasingly important. Landscape art is newer and less developed than are the commercial branches of horticulture, but many of the towns and cities possess active horticultural societies, part of the work of which is a propaganda looking toward the beautifying of home surroundings. Ontario, as a province, possesses great natural beauty. Few sections are entirely level and the general character is undulating or more or less rolling. There are many beautiful homes in towns and cities and many also throughout the countryside.

The many local horticultural societies and the provincial federation of them are exerting profound influence

Old Ontario lies farther south than any other part of Canada, the most southerly part, as a matter of fact, lying in the same latitude as Boston, Mass., and on a level with the northern boundary of the State of California. In this southern district, the production of early vegetables, both under glass and out-of-doors, has become an important industry. In the vicinity of many towns and of the large cities, such as Hamilton, Brantford, London, Toronto and Ottawa, there have also grown up important local industries in the production of vegetables. The extensive production of such truck-crops as onions, cabbage, and celery is conducted in a few small districts only, but with the rapid development of markets this phase of vegetable-growing is taking on increased importance. In certain sections, such as Prince Edward County, the vegetable industry takes the form of production for canning factories. In that county, there are some sixteen large commercial canning plants, and many additional factories are located in other sections and devote themselves to the canning of full lines of vegetables and fruits. The industry is growing.

The apple is by far the most important fruit produced within the province, but certain sections have for years been producing peaches in a large way. The Niagara Peninsula has long been famed as an important fruit center, and many fine commercial plantations of peach and other fruits are found there. Peaches from this locality are being successfully shipped to Winnipeg and northwestern markets, and a few shipments have also been landed in Great Britain in excellent condition. On the accompanying map, the three districts marked No. 1 produce peaches successfully in a commercial way. The peach section bordering on Lake Huron is of comparatively recent development, but the climate and soil

are perfectly adapted to this fruit, and a great extension of acreage has taken place in that locality within recent years. That part of district No. 1 which lies to the north of Lake Erie does not produce peaches as extensively as its area would indicate, but there are numerous localities that can and do grow large quantities of this tender fruit. The section marked No. 1 which lies south of the west end of Lake Ontario is the Niagara district of Canada, and is world-famous.

The sweet cherry as a commercial crop is found only in very few localities, and these are practically all in district No. 1. This district is also the only part of the province that grows grapes extensively, as the more northerly sections have not sufficient length of season to ripen

659. Fruit-regions (numbered) in lower Ontario.

throughout the country on all kinds of amateur horticultural work, and floriculture especially is a feature of very many home gardens and of many school and public grounds as well. In commercial floriculture, the Dale greenhouses in Brampton were until recently said to be the largest range of houses in America, and there are many other up-to-date glasshouse plants in various parts of the province.

the crop. District No. 2 produces most of the plums and pears grown commercially in the province, but the Niagara section of district No. 1 also grows these two fruits extensively. The part of district No. 2 bordering on Georgian Bay was formerly one of the most important plum districts. The only district in the province that produces pears extensively is the Burlington section, lying at the west end of Lake Ontario.

The commercial cultivation of strawberries, raspberries, gooseberries, blackberries, and of sour cherries, is extensive in many districts of the province. Local conditions, such as the presence of urban markets or of canneries, together with the availability of labor, seem to determine the localities which can engage profitably in the production of these fruits. Large quantities of even the most tender fruits, such as strawberries, are shipped west to points in the prairie provinces, and eastward in some cases to Quebec, New Brunswick and Nova Scotia.

The most important apple districts of the province are all included in districts Nos. 2 and 3. The northern, or, more correctly, the upper limit of district No. 2, forms approximately the limit of the commercial cultivation of the Baldwin apple. Other important varieties grown in district No. 2 are Northern Spy, Greening and King. That part of district No. 2 lying to the north of Lake Ontario produces few Baldwins and some Greenings, but the leading variety is probably Northern Spy. District No. 3 grows winter varieties for storage purposes and Northern Spy grown here keeps well until March or April. The counties north of Lake Ontario also produce large quantities of Ben Davis, Gano and Stark. These varieties have been exported in large quantities for many years to European markets.

The area marked district No. 4 in western Ontario lies at a much higher altitude than the surrounding districts and is consequently much colder. There are few apples grown commercially, but the climate corresponds very closely to that of the St. Lawrence River Valley, part of which on the map is also marked district No. 4. The St. Lawrence River Valley has long been noted for its McIntosh Red and Fameuse. The McIntosh Red, by the way, had its origin in Dundas County, not far from the St. Lawrence River, about 1790. (See page 317.)

District No. 5 and the large extent of country lying to the north of Lake Huron and Lake Superior, and extending to James Bay, is comparatively new and untried with regard to its possibilities in fruit-growing. In one or two districts of the great northland, apples are grown successfully in a commercial way. This is true of St. Joseph's Island, Algoma, and of the mainland of Algoma District bordering on the north shore of Lake Huron.

One of the most interesting features of Ontario horticulture is the existence within the province of a large number of very successful fruit-growers' selling organizations. The story of the work done by some of these organizations in reviving the fruit industry in certain previously neglected counties reads like romance. In Norfolk County, on the north shore of Lake Erie, the production of apples increased in ten years from nothing to approximately 50,000 barrels, and this tremendous development came about simply through the care given to the old orchards, many of which had been standing uncared for and idle thirty or forty years previous to the organization of the fruit-growers' association. There are some forty of these associations now doing business within the province, and by their aid Ontario expects in the future to be able to dispose of her fruit successfully in the face of all competition.

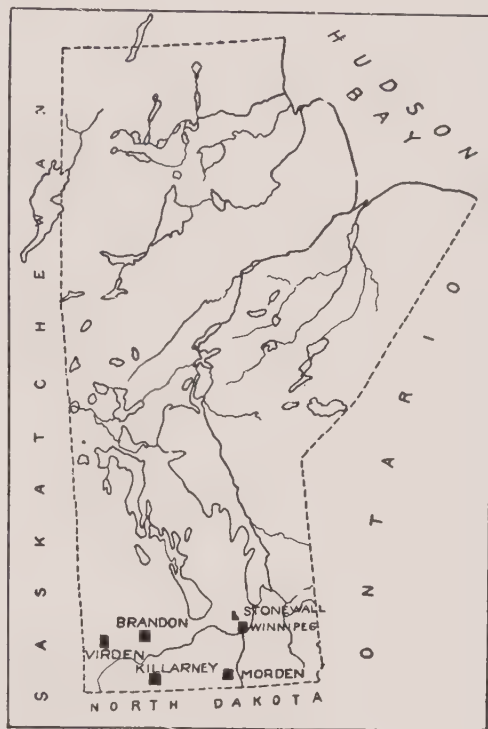

J. W. CROW.

#### Manitoba.

In considering the agricultural possibilities of the province of Manitoba (Fig. 660), the subject of horticulture is too frequently overlooked or given scant consideration. The fact that cereals can be grown with great success has been very clearly demonstrated, but up to the present time comparatively few of the persons residing in western Canada have had sufficient confidence in the fruit-growing possibilities of the country to enter the industry on a very extensive scale. However, a few pioneers have opened the way, and to the results of their work one looks for encouragement and guidance.

Geographically, Manitoba lies just north of the international boundary line, extending from longitude 95° W. to 101½° W., or about 276 miles. Since the extension of the boundary, the northern limits are on the shores of the Hudson Bay. The altitude varies from 760 to 1,500 feet above sea-level.

The annual precipitation in the Red River Valley varies from 20 to 25 inches, and in the western part of

660. Manitoba.

the province from 15 to 20 inches. The average rainfall for the growing season—May, June, July and August—varies from 8 to 11 inches.

The annual sunshine is 47 per cent of the possible, and during the growing season is 56 per cent, making an average of 8.5 hours of bright sunshine a day, which accounts for the phenomenal growth which is made by most plants.

The average monthly temperature in degrees Fahrenheit is as follows: January, 1.9; February, .5; March, 14.4; April, 38.2; May, 50.4; June, 60.6; July, 64.6; Aug, 62.1; September, 52.8; October, 40.7; November, 20.7; December, 7.5. Average temperature for the growing season from the first of May to the first of September is 59.2° F.

In a country of such rich agricultural resources as Manitoba, in which excellent crops of cereals can be produced on an extensive scale with a minimum of labor, one would naturally expect that the people would turn rather slowly to the production of fruits, which require much greater care and a much more intensive and exact system of cultivation. The growing of this finer class of agricultural products is usually delayed until the country has become thickly populated and the land has been brought into a fairly good state of cultivation. Making an allowance for the difficulties that must be overcome in the production of fruits, some excellent work has been done and substantial progress made.

Among the valuable introductions is the *Pyrus baccata*, or Siberian crab-apple, which was first planted on the experimental farm at Brandon, in the year 1890,

the trees having been grown at the Central Experimental Farm, Ottawa, from especially selected seed that had been imported from Russia. The introduction of this hardy Russian apple has done much for the advancement of apple-growing in Manitoba. It furnishes a hardy stock on which the tenderer standard varieties may be grafted and their hardiness very much increased. An effort has also been made to increase the hardiness of some of the standard varieties by hybridizing them with *Pyrus baccata*. Several promising hybrids have been produced in this way and are now being grown to some extent in the province. (See page 557).

Among the earliest attempts in fruit-growing in the district of Winnipeg, may be mentioned those of the late W. B. Hall, of Headingly. In the early sixties, some not unsuccessful experiments were conducted by him with currants, tomatoes, gooseberries, Siberian crab-apples and rhubarb. The results were indeed so satisfactory that he and others in the neighborhood were induced to undertake fruit-growing on a limited scale. Among other pioneers whose experiments on fruit-growing have been of value, may be mentioned the late Thomas Frankland, of Stonewall, A. P. Stevenson, of Dunstan, and D. W. Buchanan, of St. Charles. Mr. Stevenson has experimented with apples, plums, cherries, grapes, gooseberries, currants, raspberries and strawberries, and his untiring efforts have been a great incentive to others. He has been very successful in growing apples, particularly the hardy Russian sorts. He has at the present time a number of the better varieties of this class growing in his orchard, practically all of which are yielding good returns, his annual crop being usually over one hundred barrels. The various hardy crab apples also yield good returns. Mr. Stevenson is convinced that apples can be successfully grown in Manitoba if the proper varieties are chosen and the proper conditions provided.

The experimental farm at Brandon has accomplished much for Manitoba horticulture. Hundreds of varieties of the various classes of fruits from different parts of America and Europe have been tested there and the results published. In the month of April, 1899, about 500 fruit trees, consisting of apples, crab-apples, plums and cherries, were placed under test at the experimental farm. These included many of the large standard varieties together with a number of hardy imported kinds. Numerous varieties of grapes, currants, gooseberries, raspberries, blackberries and strawberries were also tested. Many of these plants did not survive the first winter and in a few years only the hardiest sorts were found to be alive. Since the first planting, many other varieties of fruits have been introduced and experimented with and much valuable information has been gained. Among the numerous introductions made was the Russian berry-crab, *Pyrus baccata*. Its extreme hardiness makes it eminently well suited to this country, where it is used as stock on which the less hardy sorts are grafted for the purpose of increasing their hardiness and thereby adapting them to an environment that would otherwise be uncongenial to them.

Small-fruit culture in the province of Manitoba has always been attended with a fair degree of success. Currants, gooseberries, red and black raspberries, and strawberries have been grown since the early settlement of the country. They yield profitable returns when intelligently cultivated. They apparently possess an inherent hardiness not shared by many tree fruits, which renders them much more suitable for the severe climate. It is only a matter of a few years until these smaller fruits will be grown in all parts of the province, in sufficient quantities to supply the local demand.

Another phase of horticultural work to which considerable attention is being given, is the decoration of home- and school-grounds by the planting of ornamental trees, shrubs and flowers. The prairie is bare and unattractive and around many prairie homes there has been

a lack of trees and shrubs. The work of beautifying the surroundings of residences is one of the most necessary steps in the horticultural work of Manitoba. Much has already been done in the cities, towns and rural districts by horticultural organizations to increase their attractiveness by ornamental planting.

Practically all garden vegetables, with the exception of a few that require a long season, may be grown to a high state of perfection. The richness of the soil and the shortness of the seasons tend to give a flavor and tender crispness to the vegetables not attainable elsewhere. The heavy yields that may be obtained from these gardens make vegetable-growing a very profitable branch of horticulture, as there is an abundant demand for vegetables in the home market.

The work of fostering horticulture within the province is borne largely by the Agricultural College and certain societies; among the latter are the Manitoba Horticultural and Forestry Association, the Brandon Horticultural and Forestry Society, and others of a more or less local character. The objects of these societies are to bring together those persons interested in horticulture, to assemble horticultural literature, and to stimulate in every possible way a greater interest in horticultural pursuits. Much good work has been accomplished by these societies and to their efforts is largely due the increasing interest that is being taken in the various lines of horticultural work within the province.

There are several directions in which progress may be made in Manitoba horticulture; for example, a better selection of varieties; an improvement by breeding and selection of wild and native fruits and varieties grown in the country; and improved systems of culture. Much is being done in plant-improvement in other parts of the country, and Manitoba also offers an excellent field for the improvement of native fruits. Various wild fruits grow very abundantly in many parts of the province, and if a combination could be effected whereby the hardiness and productiveness of these could be combined with the larger size and better quality of the cultivated fruit, a great step in advance would be achieved.

F. W. BRODRICK.

### Saskatchewan.

In the map (Fig. 661), all that part of Saskatchewan that need be considered here is shown in the numbered districts, the remainder farther north being still beyond the reach of settlement, although many parts of it will no doubt be found, amidst its lakes and forests, eminently suited to the growing of farm and garden products, where now the lonely trapper and the mink and marten roam. Districts Nos. 2, 3, 5 and 6 are mostly bare prairie, being slightly wooded about some of the hills, river-banks and coulees; district No. 1 has also considerable prairie, but about the center is situated the Moose Mountain Forest Reserve, while mixed prairie and scattered groves of poplar extend over the northeastern part and through districts Nos. 4, 5 and 9, with heavier timber towards the northeast in district No. 7.

The average annual precipitation has been about 17 inches, but hardly more than 15 inches in districts Nos. 2, 3 and 6. Over 12 inches of this occurs from April to September. The elevation is also greater in this southwestern portion of the province, being 2,439 feet above sea-level at Swift Current, 1,884 feet at Moosomin near the eastern boundary, and 1,432 feet at Prince Albert on the Saskatchewan River in the north.

The average mean temperature of Saskatchewan for ten years has been: January, 2.9°; February, 3.8°; March, 14.5°; April, 37.4°; May, 50.2°; June, 57.5°; July, 63.3°; August, 60.5°; September, 50.1°; October, 40.9°; November, 25.0°; December, 10.4° F.

Horticultural industries have not yet been developed

to any extent, and consequently imports of canned fruits and vegetables, fresh fruits and flowers, have been very heavy in proportion to the population, and of exports there have been none. A rapidly increasing resident and floating population, combined with the attractions of grain-farming, to some extent account for this. There is no adequate reason why vegetables, small fruits and flowers should not be grown in quantity sufficient at least to meet the demand of the home market. There is ample evidence at any of the fairs held in the various parts of the province that the soil and climate are suitable for the production of a large variety of vegetables of unexcelled quality. It has been proved that vegetables and flowers can be grown profitably under glass during the coldest winters. The most important points to consider in locating such industries are access to market and cheap fuel. A glance at the map will show many favorably situated distributing points on the network of railway lines, while the lignite of the Souris Valley in the south and the wood of the northland, readily

661. Saskatchewan.

solve the fuel problem without considering the possibilities that lie hidden in the straw piles that accumulate or are burned on the millions of acres of grain fields each season.

Small conservatories and nurseries located at Prince Albert, Moose Jaw and possibly other points, are devoting their attention mostly to winter vegetables, while at Saskatoon 25,000 feet of glass is used in the production of pot- and cut-flowers. There is also a large demand for shrubs and ornamental trees for the beautifying of the homes so rapidly growing in numbers in village, town and city, but few nurseries are specializing in that line. The abundance of native small fruits such as the currant, gooseberry, raspberry, Saskatoon, blueberry, cranberry, cherry and strawberry, has to some extent delayed the introduction of cultivated varieties into the gardens of the residents in those portions of the province most suitable for successful fruit-growing, and, on the other hand, those living on the open prairie have first to grow shelter-belts before they can hope for good gardens. When shelter is provided, the hardier varieties of small fruits and crab-apples may be grown

without difficulty. There are, however, peculiar weather conditions that should be considered before anything of this kind be attempted on a commercial scale. Bright warm days and cold nights in April, and frosts in May, determine the extent of the fruit crop. It is true, however, that some of the evil effects of freezing and thawing can be avoided by protection of the stems from the direct rays of the sun.

In isolated instances, in sheltered gardens, some of the hardiest varieties of standard apples, such as Hibernian, Anisette and Blushed Calville, are growing and some are producing fruit, but the day is yet distant when it can be said that apples are commonly grown here. The late Director of the Dominion Experimental Farms, Wm. Saunders, since the beginning of these farms, took a keen interest in the finding of suitable fruits for the prairie provinces and in the encouragement of horticulture, and has been ably assisted in this by Angus Mackay, Superintendent of the Indian Head Farm, where the Siberian crab has been found hardy enough to withstand the most severe climatic vicissitudes. This hardy crab has been used in the production of most promising hybrids and as stock on which to root-graft hardy cross-breeds. At the same station varieties of the native Manitoba plum of good quality have been developed. Work of this kind is also being undertaken at the more recently established experimental stations at Rosthern and Scott. Another institution that, under the superintendence of Norman M. Ross, has aided greatly in demonstrating to the people the possibilities in the way of landscape gardening and floral beautification of home surroundings, is the Dominion Forestry Farm at Indian Head, from which many millions of trees are distributed yearly to the farmers on the open plains to be planted, as windbreaks and shelter-belts, under expert supervision. Much encouragement was given to the horticulture of the Northwest Territories, and Saskatchewan especially, by the interest displayed by A. E. Forget, recently Lieutenant-Governor, and the skill and success of his popular gardener, George Watt, who was ever ready to advise and assist the inquiring amateur. Probably no farm in the province could boast of so attractive a garden as that of Gerald Spring-Rice near Pense, where in typical Old Country fashion its labyrinth of walks mid the choicest of flowers and shrubs, was centered by a sun-dial. Another farm on which the possibilities in the way of garden and fruit-culture have been demonstrated is that of George Harvey in the Indian Head district, where shelter-belts, shade trees and hedges provide the protection so necessary for success in horticulture and nesting-places for the birds that are of so much assistance in controlling insect form. Personal mention should also be made of John Ashworth, a member of the legal fraternity, who, from love of flowers and the pleasure of overcoming obstacles, established the Saskatoon Nursery Company, which is now a profitable industry.

So closely is bee-keeping associated with successful fruit-growing, that it may not be out of place to say that very few in this province have yet turned their attention to the production of honey, although it has been amply demonstrated that bees make honey of excellent flavor from the abundance of wild flowers on the prairie; and bees may be safely wintered notwithstanding the severity of the frost at times.

There are now only two horticultural societies in the province, one being located at Regina and in receipt of an annual civic grant, the other having been just started at Saskatoon. No direct aid to horticulture is given by the provincial government, but through the Extension Department of the University of Saskatchewan, the agricultural societies and the homemakers' clubs may draw grants founded on their prize lists, in which horticultural competitions may assume a prominent place and expert judges are furnished when required. There is no

horticultural school at present in the province, but a department of horticulture is planned for the College of Agriculture and will no doubt be equipped in the near future, but at present the only instruction given is through qualified practical horticulturists sent out by the Extension Department to address meetings throughout the province.

T. N. WILLING.

#### Alberta.

Alberta (Fig. 662), is the farthest west of the three prairie provinces of Canada. Its eastern boundary is the 110th parallel of longitude, and its western boundary for about 500 miles north is the summit of the Rocky Mountains; and beyond this point, its western boundary is the 120th parallel.

662. Alberta.

From a climatic point of view, the province naturally divides itself into four principal regions,—southern Alberta, central Alberta, northern Alberta, and the foothills or highlands district. The latitude of the northern part of the province is offset to a great degree by its lesser elevation.

Northern Alberta may be said to be that part of the province lying north of a line drawn east and west through Athabasca Landing. The whole of this district is still practically unsettled, although people are going in; a few small older settlements are scattered here and there about the fur-trading posts, and all the common garden vegetables, as well as farm crops, are grown at these places, as far north as 400 miles beyond Edmonton. Wild currants, gooseberries, strawberries, raspberries, and saskatoons or Juneberries are plentiful throughout the region. The country is more or less bush-covered or park-like, and is, in this way, protected from the winds that sweep over the open country in the

south. In view of what has been accomplished in fruit-growing in the south, at a higher altitude and under wind-swept conditions, it is reasonable to expect that at least some of the hardier apples and crabs will in time be grown successfully in the far north. The soil of northern Alberta is a deep black humous loam, and its very richness constitutes a danger from a horticultural point of view. There is usually an abundance of rainfall, and the difficulty with fruit trees under such conditions is to get them matured-up before winter. No reports are at hand as to attempts at growing fruit in northern Alberta. The distance from the railways is so great that plants are usually dried out before reaching their destination, but as railways are now being pushed north, it will doubtless not be long before promising results will be secured.

Central Alberta may be said to comprise the region lying south of northern Alberta as far as a line drawn through Red Deer to Provost near the Saskatchewan border. Its soil, climate, and other features are similar to those of northern Alberta, although the altitude in the central part of the district is greater, rising at Lacombe to over 2,900 feet. It is the oldest settled part of Alberta, and is covered with well-handled farms, whose owners, having been some years in the country, have had time to make experiments in fruit-growing. Apples have been produced near Edmonton, Ponoka and Red Deer, and crabs have been grown at the Dominion Experimental Farm at Lacombe and also at Calgary. Small fruits are grown successfully all over the district. The influence of the difference in altitude is very marked in this territory, as ornamental trees, such as the soft maple (*Acer saccharinum*) and the American basswood (*Tilia americana*) are hardy in Edmonton, while they are a failure farther south at higher altitudes, and with similar soils, shelter, and rainfall.

The Highlands of Alberta may be described as the country south of the Red Deer River, east as far as a line drawn north of the main line of the Canadian Pacific Railway, and thence running southwest to Stavely on the Calgary and Macleod line, and from that point south to a point north of Cardston, and thence east through Spring Coulee. Its western boundary is the boundary of the province. This is the highest part of the cultivable land of Alberta, rising to a height of over 4,000 feet. A very small area of the northern part of this region is wooded, the remainder being open and often wind-swept prairie, with the additional harassment in the south of the warm chinook winds. In appearance, this southern section is not unlike the country east of it, while it is still in the "dry" belt, with a rainfall reaching in certain places at times over 20 inches. It has a little more precipitation than southern Alberta to the east of it. This increased precipitation causes longer and thicker grass, and this growing and dying down for generations has left a richer soil, which in turn encourages late growth in trees. This, coupled with the often shorter season between frosts, incident to its higher altitude, will probably preclude the possibility of apple-growing becoming general in the higher districts unless in favored spots. The hardier varieties of small fruits do well in this region, and at Cardston, 12 miles from the United States boundary line, at an altitude of approximately 4,000 feet, apples have been grown by a number of persons. At Joe McFarlane's ranch about 6 miles from the Livingstone Range of the Rocky Mountains, at an altitude of over 4,000 feet, Hyslop crabs have been ripened. These successes were in sheltered situations; and while this district may never become known as apple-producing, still these cases serve to show what may be done in isolated instances in which conditions are favorable, and may be accepted as an indication of what may become more general in years to come.

Southern Alberta proper is the district lying east of the foothills, and south of central Alberta. It also has conditions peculiarly its own. The prairie is bare of trees, and while the soil is of excellent quality, it is not the black, deep, vegetable mold of the other parts of the province. It is what may be classified as a friable clay loam, that is, a rich clay loam containing enough sand to enable it to be worked easily. It is in the dry belt, and the rainfall ranges from 12 to 15 inches per annum. Being bare, it is often windswept, and gardening without shelter-belts will never be successful. It is the home of the warm chinook winds, and these may come at any time, and often in a few hours, or even minutes, a rise of temperature from 30° below zero to 8° or 10° above freezing will take place. This is an extreme change in temperature, and if the warm wave is followed, after a few days or weeks, by a cold spell, it cannot fail to be a severe trial to growing trees. These rapid changes in winter have been declared by many of the old settlers to be the cause of the scarcity of trees on the prairie. This, however, is to a large extent a fallacy, as is being now proved constantly by the successful growth of shelter-belts of suitable species all over the country, and exposed in the fullest degree to the influences of the chinooks. The lack of rainfall, however, does constitute a menace to successful fruit-growing, for if there is a scarcity of moisture in the soil in the fall, there is invariably greater risk of dead trees in the spring. Snow cannot be depended on to preserve the moisture, or to supply it, as only about twice in thirty-eight years has it lain steadily the whole winter. The dry winds drift the snow off, and the chinooks melt it, so that in winter for weeks at a time the ground may be bare of snow. Cultivation to preserve the moisture is a necessity, though irrigation in the fall, in some districts in which it can be done, is of great assistance in carrying the trees over winter. Notwithstanding all these untoward circumstances, a number of apple trees are growing and producing fruit in southern Alberta. Settlement has been general only in the last ten years, and yet in that time many successful experiments in fruit-growing have been made, possibly more in the same time than in the history of any of the other prairie provinces. Apples, crabs and plums have been growing in several gardens for the last seven or eight years in Medicine Hat, Irvine, Lethbridge, Magrath, Calgary and Macleod, and they also have been grown in several instances at Stirling and Raymond. Thus, although southern Alberta would appear at first sight to have natural conditions unfavorable to large-fruit-growing, experience shows that, in spite of these, it is possible to do so. It would seem as if the dryness of the country, intensified perhaps by the influence of the chinook, tends to ripen the annual growth before frost comes in the fall, so that the trees do not winterkill. There is no doubt, also, that the nature of the soil has much to do with this early ripening, lacking as it does the stimulating effect of the more vegetable soils of the north. Experience in grain crops and forest trees serves to bear this out. However, it is still doubtful whether southern Alberta will ever become a fruit country. The high winds that occur at any time in the spring and fall may interfere greatly with the setting or maturing of the fruit, and, as a consequence, the regularity of the supply. There is no doubt, however, about the farmer in time being able to grow fruit enough for his own use, with the help of shelter-belts. When fruit is grown under irrigation in Alberta, care must be taken to avoid irrigating after the last of June. If water is applied after that time, there is usually grave risk of winterkill, or rather fallkill, as the trees continue growing late into the fall and are not mature when the first frost comes. Even cultivation to preserve the moisture should not be carried on later than July 15.

There is no provincial horticultural society, and no state aid devoted purely to horticulture, although much

good work is being done by the experimental farms, maintained by the Dominion government. These, however, have not been able to do much as yet, having been established only six years. The chain of demonstration farms which is being established by the provincial government will probably be of some assistance in this direction. There are two fairly strong local horticultural societies at Edmonton and Calgary.

ARCH. MITCHELL.

### British Columbia.

In the time since the *Cyclopedia of American Horticulture* was published, horticulture in British Columbia (Fig. 663) has passed through the experimental stage. Although the province is one of the largest in area in Canada, its population in 1891 was only 98,000; in ten years it had almost doubled; and in twenty years the census of 1911 shows a population of 362,000, of which over half is urban in character, and located on the coast. While practical experiment has shown that different forms of horticulture can be most successfully conducted commercially under the widely diversified conditions existing throughout southern British Columbia, development has been so recent that only the fringe of its possibilities has been touched. Yet, even now the province has gained such a reputation as a fruit-growing country as to warrant a rather full description here.

Fruit-growing in British Columbia has been inspired by the success that the industry has attained in the states of Oregon and Washington directly to the south, in which conditions of climate and soil are not dissimilar, and by the rapidly increasing demand for fruit, not only by the growing population of the province, but by the phenomenal increase in demand from the Canadian prairie provinces, which cannot possibly produce all their own fruit. Early dreams of possible markets for all the horticultural products of the province have been far surpassed by the actual development of the market. The population of western Canada was in 1911 over three times as great as in 1901. On the other hand, fruit-growing is now firmly established as one of the commercial industries of the province and though lumbering, manufacturing and mining surpass agriculture in the amount of wealth now being produced, fruit-growing will in a few years aid in bringing the returns from agriculture well to the front.

In general physical features British Columbia is mountainous, the greater part of the area being covered by the Rocky, Selkirk, Cascade and Coast ranges, between which lie the valleys of the rivers and lakes in which agriculture is being practised. It is probable that about one-twentieth or one-thirtieth of the entire land is cultivable. The land is, therefore, usually fertile, and in many districts unusually so. The climate is remarkably varied. The greater part of the cultivated area of British Columbia lies within the upper austral and transition zones. On the coast the atmosphere is humid, the rainfall copious and the annual temperature has a very limited range. In the interior, continental temperature conditions prevail, and in most of the interior valleys it ranges from zero to 90° or 100° as the extremes. Some of the interior valleys have a total precipitation of only 8 or 9 inches, while others run from 35 to 40 inches. Irrigation is essential in the first-mentioned, not in the latter. A large percentage of British Columbia horticulture is conducted under irrigation. The altitude of the horticultural districts on the coast varies from a few feet above sea-level to 400 or 500 feet above. In the interior valleys the altitude runs from 800 to 2,800 feet, and even to 3,300 feet, above sea-level.

Among the tree fruits grown in the province, the apple holds preëminence, and especially is this true in the arid and humid valleys of the interior, in which many varieties of apples reach a degree of perfection

not excelled elsewhere. The interior valleys now ship about 600 carloads of apples to prairie and coast markets, and to Australia, China, Japan and England. Pears are largely planted, not only in the interior, but also on the coast where they are relatively more successful than are apples, the principal varieties being Bartlett, Clairegeau, Anjou and Flemish Beauty. Plums and prunes are also of considerable commercial importance, the Pond Seedling or Hungarian being the principal plum, although the Italian prune is more largely grown commercially than any other variety of either plum or prune. Peaches are practically confined to the Lower Okanagan valley, and the Triumph, Early Crawford, Yellow St. John and Elberta are most largely grown commercially. The total shipments probably aggregate about 100 carloads. Cherry trees are planted throughout the province on a commercial scale, the hardier sweet cherries, especially the Bing, Lambert and Royal Anne throughout the interior, while on the coast the Olivet and English Morello, both preserving cherries, meet with particular success, the growers obtaining an average of 11 cents a pound for a period of years. Not the least important among the tree fruits are the crab-apples, particularly Transcendent and Hyslop, grown most largely in the Okanagan Valley. The Transcendent is thought to be the most profitable apple for a period of years in the province. Prairie markets have recognized the superiority of the British Columbia crab-apple and are paying prices extremely satisfactory to the fruit-grower. The apricot is grown to some extent in the warmer interior valleys. Nut trees are being experimented with throughout the province and indications are that some varieties of walnuts will prove commercially profitable on the coast.

In small-fruits British Columbia has some areas, especially those contiguous to the delta of the Fraser River, that are preëminently adapted to the strawberry and raspberry; the loganberry also flourishes in the coast regions and is proving profitable. Blackberries are grown to some extent on the coast, as are currants and gooseberries, although the latter are inclined to mildew, with the exception of the Oregon Champion, a western variety now grown almost exclusively. The interior valleys, especially those having a more humid climate, are growing strawberries and raspberries commercially to an increased extent. Taken as a whole, however, the acreage in small fruits is only a small fraction of that devoted to tree fruits, and this is quite likely to be the case indefinitely.

Vegetable-growing is practised throughout the province, the white potato, onions, tomatoes, cabbage, and celery being the principal crops in the order named. The potato is grown as a field crop in practically all districts and the average yield an acre in 1911 was 230 bushels. British Columbia potatoes won the Stillwell trophy at the National Land and Irrigation Exposition, New York, 1911, which proves the general excellence of the soil and climate of the province for the crop. The potato-beetle is unknown and blight is not usually serious enough to warrant preventive measures. Potatoes are shipped in commercial quantities to the Yukon, to northern British Columbia, to the coast cities, to the mining camps and to the prairie provinces. The acreage in 1911 was about 13,000 acres and this was increased in 1912. The onions, of which the Yellow Globe Danvers is grown in the Okanagan Valley to the extent of about 100 carloads a year, are shipped to coast and prairie markets. The summer nights are too cool for the tomato except in the arid interior valleys where they are grown in large quantities both for shipping fresh and for canning purposes. Cabbage, celery and other vegetables are grown on an extensive scale commercially on suitable soils throughout the province, notably at Armstrong.

The greenhouse business surrounding the cities of the

coast, has trebled in volume in three years, and openings still remain for its extension throughout the province. Bulb-culture is making progress in the district surrounding Victoria, and will become an important commercial industry when labor becomes cheaper.

The regions are shown on the map (Fig. 663). Horticulturally British Columbia is as yet almost confined to the southern part, and only the different areas so indicated are here discussed.

Districts Nos. 1 and 2 on the map are distinctly coastal in character. The Japanese current tempers the climate throughout the entire year so that zero weather is very uncommon, and the summer temperature very rarely reaches over 80°. The humidity is high almost throughout the year, and the annual

663. Horticultural Regions of British Columbia.

precipitation (which is nearly always in the form of rain) runs from 30 to 120 inches, the average in the horticultural areas being around 55 inches. This falls largely in the winter months, and July and August are often so very dry as to cause a loss from drought. This area has a remarkably long growing season. Owing to the coolness of the nights, tomatoes, corn, and the like do not ripen. Early apples do well, but winter apples cannot be matured successfully. Fungous diseases also restrict apple-culture to a serious extent. Pears, however, do well; small-fruits do exceptionally well, and preserving cherries are very profitable. District No. 1, being the southeastern part of Vancouver Island, with an annual precipitation of about 40 inches, is rather drier than the lower mainland district No. 2, but this difference has no great influence on the character of its products. In these districts only a small proportion of the land suitable is being made to produce what it is capable of producing. The local markets still import considerable quantities of produce from California, Oregon and Washington.

XIX. Canadian orchard development.—The bench lands of British Columbia.

The second great horticultural region of southern British Columbia is the dry-belt. It lies just east of the Cascade Mountains, is about 200 miles wide and extends northwest from the interior boundary about 250 miles. In it are districts Nos. 3, 5, 6 and 7 as indicated on the map. Its valleys lie at an elevation of 800 to 1,500 feet above sea-level. The annual precipitation totals from 9 to 15 inches, distributed fairly evenly throughout the months of the year. The atmosphere is dry and bracing. Sunshine is plentiful and in the summer months almost constant. The winter extremes of temperature are lower than on the coast, and the summers are very much warmer. It is the great apple-, peach-, tomato- and potato-producing district of the province, all of its products being grown under irrigation, and mostly marketed in carloads on the coast and in the prairies. Of its valleys, the Okanagan (No. 5) is the most advanced and the largest shipper; Thompson River (No. 3) and the Kettle River (No. 7) produce winter apples and potatoes as their staple crop, while the Similkameen Valley (No. 6) produces principally peaches and winter apples.

The third great horticultural region in British Columbia may be called the semi-humid interior belt, embracing districts Nos. 4 and 8. Here irrigation for most crops is not necessary, although for small fruits it is desirable. The annual precipitation runs from 18 to 45 inches, a considerable portion of which falls as snow, while June is a month of considerable rainfall. The air is more humid than in the dry-belt and extremes of temperature of winter and summer are not so great. The humidity makes fungous diseases a problem and spraying for apple-scab is necessary. Unlike the dry-belt, it is a timbered country, and the cost of land-clearing offsets the cost of irrigation systems in the former. District No. 4, in the water-shed of Shuswap Lake, is as well advanced as the Okanagan Valley, the principal shipments from Armstrong and Salmon Arm being apples, potatoes, celery and cabbage. District No. 8, the West Kootenay, has not thus far been a shipping district, the local demand in the mining camps of Rossland, Slocan and the Crow's Nest consuming more than the locality produces.

The following tabular statement indicates the adaptabilities of the different regions:

District	Present greatest production	Best commercial plantings
1. Island.....	Strawberries, King and Wealthy apples, pears, plums, and Italian prunes.	Olivet and English Morello sour cherries, King apple, Bartlett, Clairegeau and Anjou pears.
2. Lower mainland.....	Strawberries, raspberries, plums and prunes.	Strawberries, raspberries, King apple; also the above pears.
3. Thompson Riv.	Various winter apples.	Wealthy, McIntosh, Jonathan and Wagener apples.
4. Shuswap Lake Section.....	Various winter apples.	Jonathan, Wagener, Spy and Grimes apples.
5. Okanagan Val.	Various fall and winter apples, pears, plums, peaches and prunes.	Hyslop and Transcendent crabs, Duchess, Wealthy, McIntosh, Jonathan, Wagener, Y. Newton, Spitzenberg, Northern Spy, and Rome Beauty apples.
6. Similkameen ..	Peaches and winter apples.	Jonathan, Wagener, Y. Newton, Spitzenberg, Winesap, and Rome Beauty apples.
7. Kettle River...	Fall and winter apples.	Wealthy, McIntosh, Jonathan, Wagener, Rome Beauty and King apples.
8. W. Kootenay...	Strawberries, fall and winter apples, plums, prunes and pears.	McIntosh, Gravenstein, Wagener, Jonathan and Northern Spy apples.

The Dominion census of 1891 credited fruit with a total of 6,500 acres. By 1901 this had been increased only to 7,500 acres, but in the decade just passed tree-fruit-planting has had a tremendous impetus and the acreage at the beginning of 1912 was thought to be around 40,000 acres, of which 93 per cent is apples, 4 per cent pears; the remainder, plums, prunes, cherries, apricots and peaches. The report of the provincial statistician shows that in 1911 there were 15,454 acres of vegetables, of which potatoes constitute some 13,000 acres, tomatoes and onions supplying the majority of the balance. Potatoes average 6.9 tons or 230 bushels to the acre, while other truck crops average 11.4 tons to the acre. The value of the fruit and vegetable products of 1911 was \$5,084,241.

In floriculture and in landscape gardening, British Columbia is only making the first steps. In the cities, especially those of the coast, there are many fine gardens and estates, and the coast cities are developing admirable park systems.

The exact records of the first fruit trees imported, it has not been possible to obtain. It has been learned that the Hudson Bay Company was instrumental in bringing the seeds or seedling apples from California to its forts Camosun and Langley sometime previous to 1850. These old orchards are not now in existence. Orchard-planting on the coast during the period 1850 to 1885 was almost altogether of an experimental character, and nothing commercial was expected from it. From that time, and especially after the formation of the British Columbia Fruit-Growers' Association in 1890, experiments in commercial orcharding were begun. Among the first orchards in the interior country might be mentioned those of Thomas G. Earl of Lytton; that of Fred Gartrell at Trout Creek; and that of Frank Richter at Keremeos. Later on came the planting of the Coldstream orchards owned by Lord Aberdeen, under the supervision of John Craig, and T. W. Stirling's orchard at Kelowna. All of these orchards are still in bearing and have produced the wonderful fruit that has done so much to stimulate the large plantings that occurred between 1900 and 1912.

The British Columbia Fruit-Growers' Association, founded in 1890, has been in continuous activity since that time, and has done a great deal to stimulate and encourage the fruit industry and to secure governmental aid and recognition for it. With the British Columbia Fruit-Growers' Association are affiliated all the fruit-shipment and educational fruit-growers' organizations of the province.

The provincial Department of Agriculture has done very much to stimulate interest in the industry, and to protect it from the invasion of insect pests. The Horticultural Board, organized under the auspices of the Department to study the problems connected with the industry, and especially the control of pests, has through its inspectors succeeded in keeping the province free of codlin-moth, San José scale, Colorado potato-beetle, plum curculio and many other insect pests which increase the cost of production in other districts.

Four years ago the Department organized the Horticultural Branch, which is devoted to supplying information on horticultural subjects to the many new settlers embarking in the industry. The Horticultural Branch maintains sufficient assistant horticulturists to forward this work in the various districts. It has inaugurated a series of schools to teach fruit-packing, publishes literature including a list of fruits recommended for planting, and is generally at the service of the fruit industry along these lines. The Department has done much to make the possibilities of the province known by means of advertising and inspection work, British Columbia having won the highest possible awards from the Royal Horticultural Society in London, England, against all the other colonies of the

Empire for six years in succession, fruit being every year exhibited. There are no horticultural schools in British Columbia, the nearest approach to these being the short courses conducted by the Horticultural Branch of the Department. Provision has, however, been made for an agricultural college, which is now being put under way, and in this institution ample provision will be made for investigation and experiment as well as education in horticulture. R. M. WINSLOW.

**BRÏZA** (ancient Greek name for a kind of grain, probably rye). *Graminææ*. **QUAKING GRASS**. Annual or perennial grasses, with open panicles of handsome spikelets; grown in gardens.

Spikelets several-fld., flat, triangular or heart-shaped; glumes strongly concave, these and the lemmas usually horizontally spreading.—Species 12, in temperate regions, 3 intro. into the U. S.

These and one or two others also cult. for ornament, the panicles being suitable for bouquets.

**A. Plants perennial.**

**média**, Linn. **COMMON QUAKING GRASS**. Culms erect or decumbent at base, 1–2 ft.; panicle pyramidal, many-fld., the branches stiffly spreading; spikelets nodding, 3 lines long, triangular-ovate.

**AA. Plants annual.**

**máxima**, Linn. Fig. 664. One to 2 ft.: panicle drooping, few-fld.; spikelets ovate, large,  $\frac{1}{2}$  in. long, 5 lines broad, the pedicels slender, drooping. G.M. 47:175. V. 3:246.

**minor**, Linn. Four to 15 in.: panicle erect, many-fld., the branches stiffly spreading, the branchlets capillary, spreading; spikelet triangular-ovate,  $1\frac{1}{2}$  lines long.—This species is known to gardeners also as *B. gracilis* and *B. minima*.

*B. geniculata*, Thurb. = *Eragrostis obtusa*, Munro.

A. S. HITCHCOCK.

**BRIZOPYRUM**: *Desmazeria*.

**BROCCOLI**: *Cauliflower*.

**BRODIEÆ** (J. J. Brodie, a Scotch botanist). *Liliacææ*. **BRODIEÆ**. West American cormous plants of low growth, a few of which are now becoming popular in some parts of the country for spring bloom.

Flowers several on a scape; pedicels jointed: the perianth mostly funnelliform and non-saccate, not contracted in the throat, ranging from purple to red, white and yellow; stamens 6, 3 of them sometimes reduced to staminodia: lvs. all radical, narrow, usually few, sometimes evanescent. Monographers include under Brodieæ a number of genera erected by other authors, as *Hookera*, *Triteleia*, *Milla*, *Calliprora*, *Hesperoscordum*. (The oldest generic name of the group thus constituted is *Hookera*, but Brodieæ is one of the "nomina conservanda" of the Vienna code, retained because of its general use in the 50 years following its publication and since). For horticultural purposes, it is better and more convenient to merge all into Brodieæ. In this

broad sense Brodieæ includes about 30 species, which must be divided into several groups. Monogr. by Baker, in G.C. III. 20, pp. 213, 238, 459; also Watson, Proc. Amer. Acad. Arts and Sci. 14:236. Closely related genera are *Bloomeria*, *Brevortia* and *Stropholirion*.

The brodieas are valuable for naturalizing in California and the West, as they can be grown very easily. In colder climates they are worthy a trial for the same purposes but probably better for specimen-beds or the coldframe for cutting. They bloom during May, June and early July. *B. capitata* is the earliest to flower. The flowers are very lasting and beautiful for cutting. Unless planted in large numbers they are of little value for color-massing in beds, but most beautiful and dainty when planted in rockwork or with delicate plants such as ferns, heucheras, or columbines. While there is room for much variation in the treatment of the different species, several growing well in very wet soils while others can be grown even in rock fissures or grit, it will be found that the following general treatment will bring success.

On the Pacific slope, brodieas will grow well and can be naturalized in any soil or situation except in heavy shades or generally wet places or in heavily manured or much-watered soils. When the soil is somewhat sandy or gritty, or has been lightened with road grit, spent tan-bark, leaf-mold or any light material, they will usually thrive best. It is questionable whether they are quite hardy east of the Rockies and north of Virginia. The soil should be well drained, and a winter covering of leaves should be given. Plant in the fall before the ground is frozen up, from 2 to 3 inches apart and not deeper than  $2\frac{1}{2}$  inches, water sparingly, and ripen well after flowering. It is unnecessary to lift the bulbs in the summer on the Pacific slope but probably advisable east of the Rockies, unless they are kept dry in summer by placing glass over them.

All brodieas grow readily from seeds, but it requires several years to flower them. Many species produce offsets which, if detached, soon flower. If potted early and placed in coldframes, they can be forced gently.

In the following taxonomy, the species have been thrown into four more or less marked horticultural groups.

**Group 1.**—In this group, which contains some of the best species in cultivation, the plants have a fibrous-coated flattened corm, resembling that of the crocus; not usually bulbiferous. The lvs. are few, all radical and grass-like: scapes slender but stiffly erect, naked except for bracts below the many-fld. umbel; fls. usually broadly tubular, borne on slender pedicels, in purples, white and yellow; anther-bearing stamens 6. All are hardy, but a protection of straw or lvs. is advisable in the colder regions. A light, loose, well-drained, sandy or loamy soil best meets their needs, and an excess of moisture and very rich soils are to be avoided.

A. Segms. equaling or exceeding the perianth-tube.

1. *ixioides*, Wats. Dwarf, 3 in. to 2 ft.: lvs. linear, fleshy; fls. few to many, on pedicels 1–4 in. long, in shades of yellow and often purple-tinged, 1 in. or less long; filaments winged, 2-toothed above. S. Calif. to Ore. B.R. 1590. B.M. 3588 (as *Calliprora lutea*). G.C. III. 20:459.—Many handsome varieties. The best is var. *splendens*, Hort., with large, bright yellow fls..

664. *Briza maxima*. ( $\times \frac{1}{2}$ )

the limb wheel-shaped. Var. *minor*, Hort. Dwarf: fls. yellow, with dark band and blue anthers. Var. *erecta*, Hort. Dwarf.

2. *hyacinthina*, Bailey (*Triteleia hyacinthina*, Greene). From 1–2 ft.: lvs. linear: fls. 10–30, 1 in. or less long, milky white or purplish. Calif.—Perhaps this and *B. lactea* are forms of one species.

3. *lactea*, Wats. (*B. hyacinthina* var. *lactea*, Baker). In the type, has the habit of *B. laxa*, but the fls. have a short tube with a rotate corolla, and are white, with green midvein; filaments deltoid. Calif. to Brit. Col., in many forms. Watson combines the *Hesperoscordum lacteum* and *H. hyacinthinum* of Lindley, B.R. 1639, into this species *B. lactea*, thereby not recognizing a *B. hyacinthina*. Baker, however, unites the *B. lactea* form with *B. hyacinthina*, describing var. *lactea* as “more slender than the type, with white fls. and longer pedicels.” G.C. III. 20:459.—Var. *lilacina*, Wats., is much stronger, very bulbiferous, grows in wet, heavy soils, and has a larger fl., which is usually lilac-colored. Var. *major*, Purdy. Like var. *lilacina*, but fls. white.

4. *gracilis*, Wats. A tiny species, with small yellow fls.: scape 2–4 in. and purplish: lf. 1: fls.  $\frac{1}{2}$  in. long, on pedicels of equal or greater length; filaments elongated and very slender. S. Ore.

AA. Segms. shorter than the tube.

5. *laxa*, Wats. Strong plant, 1–2 ft.: lvs. linear: fls. many, broadly tubular, purple; tube very narrow, and exceeding the segms.; filaments very slender; stamens in 2 rows. N. Calif. B.R. 1685 (as *Triteleia laxa*). G.C. III. 20:241.—Showy, and one of the best. There are many variations.

6. *candida*, Baker (*Triteleia candida*, Greene). Much like *B. laxa* in character of bloom, but fls. only 6–10, and segms. white or bluish with a green vein, and the fls. set at an angle on the pedicel, so that they all face one way: further distinguished by early flowering and the very broad and glossy, scarcely carinate lvs. Calif.

7. *pedunculâris*, Wats. (*Triteleia pedunculâris*, Lindl.). Still stouter (1–2 ft.), with smaller and fewer white fls. on pedicels a few inches to a foot long; filaments short or none. N. Calif. G.C. III. 20:243.—This species grows in wet, heavy ground close to water, and is very cormiferous.

8. *Bridgesii*, Wats. Fig. 665. Similar to *B. laxa*, but stamens in one row, corolla with a spreading limb and sub-cylindrical tube, and color reddish purple; filaments deltoid. Cent. Calif. G.F. 1:126 (adapted in Fig. 665).—Grows a foot or more high.

9. *Hendersonii*, Wats. Resembles *B. Bridgesii*: yellow, banded purple: filaments somewhat winged, but not deltoid: small-flid. S. W. Ore.

Group 2.—Corm not flattened, bearing many strong offsets, the coating hairy and reddish: lvs. linear and grassy: scapes stiff, few-flid.; fls. large, of a thick, waxy opaque texture, funnellform (except *B. Purdyi*), very lasting, usually purple, in an open umbel; perfect anthers 3. These brodieas are native to a heavy soil, in rather moist situations, and are hardy. They will thrive under conditions recommended for Group 1. (*Hookera*).

A. Fls. funnellform, with a prominent tube.

B. Scape not rising above ground.

10. *terrestris*, Kellogg (*H. terrestris*, Brit. & Greene). Scape short or practically none, the umbel sitting on the earth: lvs. nearly terete: fls.  $\frac{3}{4}$ –1 in. long; staminodia emarginate, yellowish; anthers sagittate-oblong. Cent. Calif., along the coast.

BB. Scape evident.

c. Staminodia as long as anthers, or longer.

11. *grandiflora*, Smith (*H. coronaria*, Salisb.). Scape 4–10 in. high: lvs. nearly terete, dying before the fl.-st.

appears: fls. 3–10, bright blue, of good size (1 in. or more long), segms. longer than tube, very lasting; staminodia obtuse; anthers linear. Calif. to Brit. Col. B.R. 1183. B.M. 2877. G.C. III. 20:213.

12. *californica*, Lindl. (*H. californica*, Greene). Much like *B. grandiflora*: scape longer (12–30 in.); fls. 10–25,  $1\frac{1}{2}$ –2 in. long, rose to deep purple; staminodia linear and cuspidate. N. Calif. G.C. III. 20:215.—“The finest species for garden purposes,” according to Baker.

13. *minor*, Wats. (*H. minor*, Greene). Much like a small *B. grandiflora*: scape very slender, 3–6 in.; fls. 2–6 and only  $\frac{1}{2}$ –1 in. long; staminodia broad and usually emarginate; anthers oblong. Calif. to Ore.

14. *stellâris*, Wats. (*H. stellâris*, Greene). Low: scape with long pedicels and 3–6 bright purple fls., with white centers: lvs. nearly terete: anthers winged behind: staminodia white, longer than the stamens, emarginate. N. Calif. G.C. III. 20:213.—Very pretty.

15. *rosea*, Baker (*H. rosea*, Greene). About 3–6 in.: lvs. nearly terete: fls. 5–8, under 1 in. long, rose-red; filaments dilated; staminodia white, obtuse and entire, longer than the anthers. N. Calif. G.C. III. 20:213.—A pretty species.

cc. *Staminodia markedly shorter than anthers.*

16. *Orcuttii*, Bailey (*H. Orcuttii*, Greene). Plant rather stout, a foot or more high: lvs. linear, flat or nearly so: fls. 5–15, less than an inch long, short-tubed, lilac; staminodia a small triangular scale, or none. S. Calif. G.C. III. 20:215.

17. *filifolia*, Wats. (*H. filifolia*, Greene). From 6–12 in.: lvs. slightly flattened: fls. 3–6,  $\frac{3}{4}$  in. or less long, dark-colored; staminodia triangular, twice shorter than the anthers. S. Calif.

AA. Fls. short and flaring.

18. *Purdyi*, Eastw. Different from others in having a short-tubed fl. with broadly spreading, declinate segms., the throat constricted. Cent. Calif., in Sierras.

Group 3.—Corm long and cormiferous: lvs. grassy: scape tall, slender and flexuous; fls. small, in close, head-like umbels, the separate fls. waxy and narrowly tubular; perfect anthers 3, except in *B. capitata*. These species thrive in a loose, perfectly drained, loamy soil, with some humus. Hardy. The species are not readily distinguished. All are from Cent. Calif. to Wash. Known as California hyacinths.

A. Anthers 3.

19. *congêsta*, Smith. Tall (2–3 ft.), with a globular head of purple fls.: lvs. somewhat terete, perishing: fls. 6–12, sessile or nearly so,  $\frac{3}{4}$  in. long; filaments 0,

665. *Brodiea Bridgesii*. (plant  $\times \frac{1}{2}$ )

staminodia purple, 2-toothed. Calif. to Wash. G.C. III. 20:213.—Blossoms late.

20. *multiflora*, Benth. (*B. parviflora*, Torr. & Gray). Similar to *B. congesta*: fls. 6–20, sessile or short-stalked, imbellate,  $\frac{3}{4}$  in. long, blue; staminodia lanceolate, entire. Calif., Ore., Utah. B.M. 5989.

AA. *Anthers 6*.

21. *capitata*, Benth. (*Milla capitata*, Baker. *Dichelostemma capitata*, Wood). Lower (1–2 ft.): lvs. narrow-linear, perishing: fls. many, in a capitate umbel,  $\frac{3}{4}$  in. or less long, lilac (a var. *alba*); three inner anthers winged. Calif., Utah, New Mex. B.M. 5912. G.C. III. 20:238.—Early blooming.

Group 4.—Corm as in Group 1: fls. many, in a dense, or at least a close, umbel, the tube about as long as the segms.; good anthers 6.

A. Fls. essentially capitate.

22. *Douglasii*, Wats. (*Triteleia grandiflora*, Lindl. *Milla grandiflora*, Baker). Lvs. linear: scape  $1\frac{1}{2}$ –2 ft.; fls. few, in a close umbel, saccate as in *Brevoortia coccinea*, blue; segms. as long as the tube, the inner ones wavy; filaments winged. Ore and Wash. B. M. 6907.

23. *Howellii*, Wats. (*Triteleia Howellii*, Greene). Fls. bell-shaped, white: differs from *B. Douglasii* in smaller fls., and segms. not more than half so long as tube. Wash. B.M. 6989.

Var. *lilacina*, Hort. One of the handsomest of all brodieas, and a good grower: fls. porcelain-blue, suggestive of *Brevoortia coccinea*. Wash. G. C. III. 19:767; 20:239. Gn. 46:502.—Large and strong.

AA. Fls. in a close but rather free umbel, the pedicels usually larger than the perianth.

24. *Pálmeri*, Wats. Fig. 666. Lvs. firm and linear: fls. many,  $\frac{1}{2}$  in. long, the segms. about as long as tube, blue. S. Calif. G.F. 2:245 (adapted in Fig. 666).

*B. coccinea*, Wats.=*Brevoortia*.—*B. cracea*, Wats. 1 ft. or more: fls. 6–15, yellow. N. Calif.—*B. insularis*, Greene. Like *B. capitata*, but more robust and larger-fl. Islands off Calif.—*B. Lemmonæ*, Wats. 1 ft.: fls. small, deep orange. N. Ariz.—*B. leptandra*, Baker. 1 ft. or less: fls. 2, purple. Calif.—*B. klacina*, Baker. 1 ft. or less: fls. 10–15, lilac-purple. Calif.—*B. ligens*, Baker. Like *B. ixioides*, but fls. saffron-color within and brown-black on tube and ribs. Calif.—*B. pulchella*, Greene. Probably the same as *B. congesta*.—*B. scabra*, Baker. Like *B. ixioides*, but scabrous: fls. bright yellow. Calif.—*B. volubilis*, Baker=Stropholirion.

CARL PURDY and L. H. B.

**BROMÈLIA** (Bromel, a Swedish botanist). *Bromeliaceæ*. Hothouse plants, grown for the stiff form and clusters of flowers.

About two dozen species of Trop. American herbs, with stiff, pineapple-like lvs., and fls. in heads or panicles; corolla 3-parted; calyx of 3 ovate-oblong sepals. Differs from *Billbergia* and *Ananas* in technical characters, particularly in the deeper-cut calyx. Less popular as stove plants than *Æchmea* and *Billbergia*. *B. bracteata* and *B. macrodonites* of trade-lists belong to *Ananas*. Culture as for *Billbergia*, which see. Monogr. by Mez, in De Candolle's Monogr. Phaner. 9.

**Pínguín**, Linn. PINGUIN of Jamaica. WILD PINE Three to 4 ft. high: lvs. broad-toothed and spiny, bright green, but becoming pink and red with age: fls. reddish, pubescent, in a dense panicle, with a mealy rachis, the sepals acute: fr. as large as plums, acid. W. Indies.—Makes a good hedge in tropical countries, and the fr. yields a cooling juice.

**Binôti**, Morr. Panicle lax; sepals rounded at the top: habit open and spreading. Brazil.

*B. longifolia*, Rudge=Streptocalyx.—*B. tricolor*, Sanders. Lvs.  $1\frac{1}{2}$ –2 ft. long,  $1\frac{1}{2}$ –2 in. wide, the wavy margins creamy yellow except at the rose-red base, the central portion a glossy green. G.C. III. 43:261.

L. H. B.

GEORGE V. NASH.†

**BROMHEADIA** (Sir Edward F. Bromhead, English naturalist). *Orchidaceæ*. Stove orchids, terrestrial or epiphytic, non-bulbous, little known in cult., comprising two species from the East Indian–Malayan region.

Leaves distichous, rigid, often fleshy: fls. showy, white and orange, the parts narrow and pointed; lip 3-lobed, narrow. Prop. by division or offsets after flowering. *B. Finlaysonianæ*, Reichb. (*B. palustris*, Lindl. *Grammatophyllum Finlaysonianum*, Lindl.). Root of stout and fleshy fibers: st. 3–8 ft., with sheathing scales below and a few oblong thick or fleshy lvs. at the middle and elongated scaly peduncle at the top: fls. white, fragrant, the parts  $1\frac{1}{2}$  in. long, oblong-acuminate and nearly equal, spreading; lip oblong, 3-lobed, white outside and purple-lined inside, the middle lobe rounded and yellow at center. B.M. 4001.

**BROMPTON STOCK**: *Matthiola*.

**BRÔMUS** (ancient Greek name for the oat). *Gramineæ*. BROME-GRASS. Annual or perennial grasses with large, usually awned spikelets in panicles.

Spikelets several-fl.; lemmas convex or keeled, 5–9-nerved, usually 2-toothed at apex and awned from between the teeth, sometimes awnless, the awn usually straight.—Species about 100, mostly in the north temperate zone.

The genus contains a few forage grasses and several annual species that have been intro. into the U. S., especially on the Pacific coast, where they have become troublesome weeds. Among the weedy annual species may be mentioned *B. secalinus*, Linn., chess or cheat, with smooth sheaths, drooping panicles of ovate short-awned spikelets, the lemmas convex and smooth; *B. commutatus*, Schrad., resembling the preceding but the sheaths hairy; *B. mollis*, Linn. Resembles chess, from which it differs by its hairiness and more erect panicle; *B. villosus*, Forsk., with large few-fl. spikelets, the awns about 2 in. long; *B. tectorum*, Linn., delicate, slender spikelets in drooping panicles the awns 6–7 lines long; *B. rubens*, Linn., with erect compact panicles of purple spikelets, the awn 9–11 lines long. The last 3 are especially abundant in Calif. Cheat is used for hay in Ore.

A. Plants perennial, producing rootstocks.

**inermis**, Leyss. Awnless BROME-GRASS. Erect, 2–4 ft.: panicle narrow, the branches ascending or spreading in fl.; spikelets about 1 in., the lemmas mucronate or short-awned. Intro. from Eu. Gn. 25, p. 429. Dept. of Agric., Div. of Agrost., 7:298.—Used as a pasture and meadow grass in the northwestern states. Especially valuable in semi-arid regions.

AA. *Plants annual or biennial.*

B. *Spikelets awnless or nearly so.*

**brizæformis**, Fisch. & Mey. One to 2 ft.: panicle 2-6 in., one-sided, nodding; spikelets oblong-ovate, strongly flattened, as much as 1 in. long, 5 lines wide. Eu. Dept. of Agric., Div. of Agrost., 7:298.—A handsome ornamental.

**unioloides**, HBK. (*B. Schraderi*, Kunth). Fig. 667. KESCU-GRASS. SCHRADER'S BROME-GRASS. Two to 3 ft.: sheaths pilose; blades narrow, scabrous: panicle erect, open or narrow, the branches ascending; spikelets 1 in. long, compressed, the lemmas keeled, strongly nerved, acuminate, glabrous or scabrous. Andes. Dept. of Agric., Div. of Agrost., 7:299; *ibid*, Circ. 26:1.—Grown in the southern states as a forage grass.

BB. *Spikelets long-awned.*

**macröstachys**, Linn. One to 2 ft.: panicle narrow, compact, consisting of a few large spikes  $\frac{3}{4}$ -1 in. long; awns spreading or recurved,  $\frac{1}{2}$  in. long. Eu.—Sometimes cult. for ornament.

**madritensis**, Linn. Fig. 668. One to 2 ft., tufted: panicle erect, 2-4 in., oblong-ovoid, contracted; glumes and lemmas narrow, the latter 7-9 lines long; awn straight or somewhat curved, 8-11 lines long. Eu.—Sometimes cult. for ornament.

*B. pratensis*=*Festuca elatior*.

A. S. HITCHCOCK.

667. *Bromus unioloides*.  
( $\times \frac{1}{2}$ )

BROOM: *Cytisus* and *Genista*.

**BROOM-CORN**. Brooms are made of the rays or peduncles of the flower-cluster of *Andropogon Sorghum* (*Sorghum vulgare*), the species which in other forms is known as sorghum, kafir, and Guinea corn. For cultivation of broom-corn, see Cyclo. Amer. Agric., II, 216.

**BRÓSIMUM** (Greek, *edible*). *Moracæ*. A genus of 8 species of large trees of Trop. Amer., yielding edible fr.: fls. monœcious, or rarely dicecious, inside or on the outside of a fig-like receptacle. *B. Alicastrum*, Swartz, is the bread-nut of Jamaica, but it is not grown within the U. S., except in most of the botanic gardens. It bears round yellow fr., about an inch in diam., containing a single large seed, which is edible after roasting. The tree has shining lance-elliptic entire lvs. Prop. by cuttings of young wood in a bell-jar with bottom heat.

**BROUGHTONIA** (named in honor of an English botanist, Arthur Broughton). *Orchidacæ*. Epiphytic orchids, requiring stove conditions.

Pseudobulbs, 1- or 2-lvd., ovoid or globose; infl. terminal, simple or somewhat branched; sepals and

petals similar, somewhat spreading, the latter a little the broader; lip sessile on the base of the column or sometimes a little adnate, lateral lobes inclosing the column, middle lobe spreading; ovary extended into a long cavity; pollina 4, waxy.—A West Indian genus of 2 or 3 species. Sometimes united with *Epidendrum*.

**sanguinea**, R. Br. Pseudobulbs up to 2 in. long, 2-lvd.: lvs. 2-4 in. long, leathery, linear-oblong; racemes of 5-10 fls. about  $1\frac{1}{2}$  in. across and of a crimson-purple; sepals lanceolate, acute; petals oval-oblong; lip nearly orbicular, denticulate on the margin. Jamaica. B.M. 3076, 3536 (as *B. coccinea*).

GEORGE V. NASH.

**BROUSSONETIA** (after T. N. V. Broussonet, a French naturalist). *Moracæ*. Ornamental trees or shrubs, grown chiefly for their large handsome foliage.

Leaves alternate, petioled, serrate, undivided or lobed: fls. dicecious, apetalous, the staminate in cylindrical, nodding catkins, with 4-parted calyx and 4 stamens, the pistillate in globular heads with a tubular perianth including the stalked ovary; stigma filiform: collective fr., a dense globose head consisting of the persistent perianths and bracts with numerous small 1-seeded drupelets protruding at maturity and orange red.—Three species in E. Asia, and there often cult., the bark being used for paper-making.

These are deciduous trees with wide-spreading branches, under culture often shrubby, with rather inconspicuous greenish white flowers. *B. papyrifera*, the hardier of the two species in cultivation, is fairly hardy as far as north New York. It is usually a small tree with a rather low wide-spreading head and may be used in cities in situations in which small shade trees are wanted, as it stands heat and dust well. It is not particular as to the soil.

Propagation is by seeds, sown after maturity or in spring, by greenwood cuttings under glass, or by cuttings of ripened wood, kept in colder climates during the winter in the greenhouse; also by root-cuttings with slight bottom heat and layers. The varieties are also sometimes budded in summer or grafted in early spring on the roots of the type in the greenhouse. Known as paper mulberries.

**papyrifera**, Vent. (*Morus papyrifera*, Linn.). Tree, 30-50 ft., with thick, pubescent branches: lvs. long-petioled, usually cordate-ovate, acuminate, coarsely dentate, often deeply lobed, especially on younger plants, rough above, pubescent beneath, 3-8 in. long: fr.-heads  $\frac{3}{4}$  in. across, red. May. China, Japan. B.M. 2358. S.I.F. 1:38. Var. *cucullata*, Ser. (*B. navicularis*, Lodd.). Lvs. small, concave and curled upward. G. W. 6:601. Var. *laciniata*, Ser. (var. *dissecta*, Hort., var. *Bilardii*, Hemsl.). Lvs. finely dissected into very narrow lobes, often reduced to the nerves and only at the end with a small lanceolate or ovate-lanceolate lft. R.H. 1878, pp. 374, 375. Gn. 15, p. 53.—Very distinct form, low and shrubby, more tender than the type. Var. *macrophylla*, Ser. Lvs. large, usually undivided. Var. *leucocarpa*, Audib. Fr. white.

**Kazinòki**, Sieb. (*B. Sieboldii*, Blume. *B. Kaempferi*, Hort.). Branches slender, glabrous at length: lvs. short-petioled, ovate or ovate-oblong, nearly glabrous, only somewhat rough above, entire or 2-3-lobed, 2-8 in. long: fr.-head less than  $\frac{1}{2}$  in. diam.

668. *Bromus madritensis*.  
( $\times \frac{1}{4}$ )

China, Japan. I. T. 2:45.—This species is more tender than the former. It is cult. sometimes as *B. Kaempferi*, while the true *B. Kaempferi*, Sieb., with the lvs. resembling in shape those of *B. Kazinoki*, but much smaller and pubescent, and with very small fr.-heads, seems not be in cult.

ALFRED REHDER.

**BROWALLIA** (after John Browall, Bishop of Abo, Sweden). *Solanaceæ*. Mostly blue-flowered greenhouse and garden herbs.

A genus of about 6 S. American annuals, with abundant blue, violet or white fls. which are solitary and axillary, or in more or less 1-sided racemes; corolla-tube 15-nerved, straight, which distinguishes it from *Streptosolen*, in which the corolla is twisted.

The seeds may be sown in the open border, but for the sake of the earlier bloom it is better to start them indoors in early spring and transplant into the open about May 15, where they will bloom profusely all through our hot, dry summers, and until frost. They can be grown in poorer soil than most half-hardy annuals, and make excellent bedding-plants. They are also used for winter decoration, the seeds being sown in midsummer, earlier or later according to the size of the specimens desired. They should be placed near the glass and frequently stopped, in order to produce compact plants. Large specimens are excellent for cutting, and small potted plants should be grown more commonly by florists for home decoration at Christmas. It is even possible to lift flowering plants from the open before the first frost of autumn and pot them for con-

669. *Browallia speciosa*, and a flower (at e) of *B. demissa*. ( $\times \frac{1}{2}$ )

servatory decoration, although the flowers are likely to become successively smaller. Blue flowers are rare in winter, and browallias are especially desirable for their profuse bloom all through winter and early spring. The flowers are, however, likely to fade, especially the purple ones. In pots under trees, *B. speciosa* makes an excellent summer plant.

In the names of the early species, Linnæus commemorated the course of his acquaintanceship with Browall: *elata*, reflecting the exalted character of their early intimacy; *demissa*, its rupture; and *alienata*, the permanent estrangement of the two men.

A. Corolla-segms. long, acute or acuminate: corolla-tube at least 1 in. long.

*speciosa*, Hook. Fig. 669. Lvs. sometimes opposite, sometimes alternate: fls. much larger than in *B. grandiflora*, all solitary, axillary; peduncle shorter than the lvs.; corolla-tube thrice as long as the calyx, and abruptly swollen at the top beneath the limb; limb of 5 ovate, striated, dark purple segms., pale lilac beneath. Colombia. B.M. 4339. P.M. 16:290.—There are blue-, violet- and white-fl. varieties. Var. *major*, Hort., has violet fls. 2 in. across. R.B. 20:240. *B. gigantea*, Hort., is a florists' variety, with very deep blue fls. and long-blooming habit. Intro. into American trade in 1899.

AA. Corolla-segms. short, 2-lobed or notched: corolla  $\frac{3}{4}$  in. long or less.

B. Upper lvs. not stalked: fls. all in loose racemes; calyx not hairy.

*grandiflora*, Graham (*B. Roëzlii*, Hort.). St. and lvs. glabrous, or in the upper part of the plant minutely clammy-puberulent: lvs. ovate, the lower petioled: calyx-teeth oblong, somewhat obtuse, equal, scarcely shorter than the tube, spreading: corolla white or pale blue, the limb wider than in *B. demissa*. Peru. B.M. 3069.—In *B. Roëzlii*, said to be from the Rocky Mts., some fls. are white, some pale blue. The name is unknown in N. American botanical literature. No dark blue or violet-colored forms are advertised.

BB. Upper lvs. stalked: fls. solitary and axillary below, racemose above.

c. Calyx hairy.

*demissa*, Linn. (*B. elata*, Linn.). Fig. 669. St. and lvs. pubescent or glabrous: lvs. ovate, with longer stalks than in *B. grandiflora*: calyx-teeth acute, unequal, much shorter than the corolla-tube. The lvs. are variable, cuneate, rotund, or rarely cordate. S. Amer. B.M. 34; 1136. The following are now referred to the above: *B. americana*, *B. elata*, *B. elongata*, *B. nervosa*. This species is the commonest, and is usually known as *B. elata*. Blue, violet, white and dwarf forms are cult.

cc. Calyx sticky or clammy.

*viscosa*, HBK. (*B. pulchella* and *B. Czerniakowskiæna*, Hort.). Plant viscous-pubescent: lvs. short-petioled, ovate, rough-hairy on both sides: pedicels a little shorter than the calyx: calyx-teeth very clammy, oblong, shorter than the corolla-tube. The lvs. are similar to *B. demissa*, but the habit is stiffer and the fls. more numerous. The calyx-teeth spread less than in *B. grandiflora*. S. Amer.

*B. americana*, Linn., is considered by some a separate species from the above, but in Germany, where most seeds of annual fls. are grown, it is used by Siebert & Voss (in Vilmorin's Blumengärtnerei) to include *B. demissa*, *B. elata* and other forms.—*B. Jamesonii*, Benth.—*Streptosolen Jamesonii*.—*B. pulchella*, Hort., is likely to be either *B. grandiflora* or *B. viscosa*.

WILHELM MILLER.  
N. TAYLOR.†

**BROWNEA** (Patrick Browne wrote a history of Jamaica). Sometimes written *Brownæa*. (*Hermesias*, Loeffl.). *Leguminosæ*. A group of 10 small evergreen trees of Trop. Amer., allied to *Amherstia* and *Bauhinia* but little known in the American trade. Lvs. alternate and pinnate: fls. showy, red, in dense terminal or axillary clusters. Cult. in hothouses. *B. Ariza*, Benth. (*B. princeps*, Lind.) has drooping heads of scarlet fls. I.H. 42:38. *B. grândiceps*, Jacq. Fig. 670. Fls. red, in capitate spikes: lfts about 12 pairs, lance-oblong. S. Amer. B.M. 4859. G.M. 31:115. *B. Rôsa-de-Mônte*, Berger. Fls. scarlet, in dense heads: lfts. 2-3 pairs, oval, acuminate. S. Amer.

N. TAYLOR.†

**BRUCKENTHÁLIA** (after S. von Bruckenthal, an Austrian nobleman). *Ericaceæ*. Ornamental shrub, chiefly grown for its profusely produced small spikes of pink flowers.

Leaves linear, whorled; fls. in short racemes; calyx campanulate, 4-lobed; corolla campanulate with 4 triangular lobes; stamens 8, included, connate at the base; disk rudimentary; caps. subglobose, 4-celled, loculicid, many-seeded. — One species in S. E. Eu. and Asia Minor. Very closely related to *Erica*, but differs chiefly in the calyx being lobed only to the middle, not 4-parted, in the rudimentary disk and the connate stamens.

670. *Brownea grandiceps*. (×1-12)

hardy North and requiring the same treatment as hardy ericas; a pretty little plant for rockeries. Propagation is usually by seeds which are freely produced in cultivation and treated like those of *Erica*; also by cuttings.

**spiculifolia**, Reichb. (*Erica spiculifolia*, Salisb. *B. spiculiflora*, Benth.). Tufted shrub, 5-8 in. high; lvs. about  $\frac{1}{2}$  in. long; fls.  $\frac{1}{2}$  in. long; anthers obtuse, 2-lobed at the apex, style exserted. June, July. B.M. 8148.

ALFRED REHDER.

**BRUGMANSIA**: *Datura*.

**BRUNÉLLA** (probably from old German *breune* or *braune*, quinsy, which it was thought to cure). Often written *Prunella*, which was the spelling used by Linnaeus. *Brunella* is pre-Linnaean. *Labiatae*. Low-growing hardy herbaceous perennials.

Flowers usually violet or purple, produced all summer on heads an inch or more high or in bracted spikes; calyx reticulate about 10-nerved and 2-lipped, which distinguishes it from the closely related *Physostegia*, in which the calyx is almost regular.

They are best suited for the rockery and slightly shaded parts of the border, succeeding in almost any soil that is not excessively dry.

**vulgâris**, Linn. SELF-HEAL. HEAL-ALL. Lvs. ovate-oblong, entire or toothed, usually pubescent; corolla violet or purple, rarely white,  $\frac{1}{2}$ - $\frac{3}{4}$  in. long, not twice as long as the purplish calyx. Amer., Eu., Asia.—One of the most cosmopolitan of all plants, being too common in the wild to be cult. A form with variegated lvs. is rarely found wild. Herb considered astringent and vulnerary. Var. *laciniata*, Hort., not Linn. Lvs. much cut and torn; fls. as in the type.

**grandiflora**, Jacq. (*B. pyrenæica*, Phillipe). Lvs. often toothed, especially at the base; corolla over 1 in. long, more than twice as long as the calyx. Eu. B.M. 337.—Perhaps the best of the garden kinds. Var. *alba*, Hort. Fls. pure white.

**Webbiâna**, Hort. Lvs. shorter than in *B. grandiflora*, and not so pointed; fls. very freely produced, more than twice as long as the calyx, bright purple. June-Sept.

N. TAYLOR.†

**BRUNFELSIA** (Otto Brunfels, physician and botanist of the sixteenth century). *Francisceæ*. *Solanaceæ*. Trees and shrubs, a few of which are grown in warm glasshouses.

Leaves entire, oblong, often shining; fls. in terminal cymes or clusters, or solitary, large and showy, sometimes fragrant; corolla with 5 rounded and nearly equal spreading lobes (or 2 of them a little more united); stamens 4, in the throat of the corolla, the anthers all alike: fr. berry-like.—Species above 20, in Cent. and S. Amer. and W. Indies.

Brunfelsias are usually winter-flowering plants. The wood must be well ripened before flowering begins. Grow in a rich open compost, and feed liberally when well rooted. They need a night temperature of 50°. They bloom best when pot-bound. Propagated by cuttings from the new growth in spring, or from pieces of the ripe wood in autumn inserted in very sandy soil and peat and kept close and shaded until rooted. The plants are of easy culture when the simple requirements are understood. Under glass, the bloom begins usually in October and November. They are showy open-air plants in Florida and southern California.

A. Fls. violet or bluish, sometimes fading to white.

**calycina**, Benth. (*Francisceæ calycina*, Hook. *F. pauciflora*, Benth. *F. confertiflora*, Moore. *Besleria inodora*, Vellozi). Habit erect or spreading, branching freely from the base upwards; lvs. shortly petiolate, numerous, glabrous or nearly so, 3-4 in. long, elliptic or elliptic-ovate, acute, rich dark livid green above, pale green below; fls. rich dark purple in dense terminal or axillary cymes; pedicels an inch long; limb salver-shaped, with slightly wavy margins; calyx  $\frac{3}{4}$ -1 in. long, tubular, light green. Brazil. B.M. 4583.—Extremely variable in the size of the fls. and lvs. Some of the most distinct forms have been described as species by various botanists. All have fls. of some shade of purple and are here included as varieties. The following are well-marked forms in cult.:

Var. **eximia** (*Francisceæ eximia*, Scheidw.). A fine free-flowering variety intermediate in size between the type and var. *macrantha* and characterized by the long slender slightly curved and hairy calyx, which is about  $1\frac{1}{4}$  in. long; fls. rich purple on first-opening, but soon fading to almost pure white, about  $1\frac{1}{2}$  in. diam.; calyx rather long for the genus, tube extending to three-fourths its length; whole plant slightly downy. B.M. 4790. F.S. 10:1037.

Var. **floribunda** (*B. floribunda*, Hort.). A dwarf floriferous shrub of free-branching habit and glabrous in all parts: lvs. 2-4 in. long, elliptic, rich dark livid green color, glabrous, and prominently veined on the under sides; fls. rich violet, with small white eye; limb flat or nearly so; calyx  $\frac{5}{8}$  in. long, elliptic in outline; pedicels stout,  $\frac{1}{2}$  in. long.—Largely grown by European nurserymen in recent years. A pretty and desirable form, as it flowers rather early in the year without any extra heat.

Var. **macrantha** (*B. macrantha*, Lem. *B. grandiflora*, Don. *B. Lindeniana*, Nichols.). Fig. 671. A magnificent form of strong and vigorous habit, with rich dark green lvs. often as much as 8 in. long and  $2\frac{1}{2}$  in. broad, glabrous or nearly so in all parts, except the upper part of the corolla-tube: fls. in dense axillary or terminal cymes in the axils of all the upper lvs., rich deep purple in color, with prominent ring of lavender-blue color surrounding the white eye at the mouth of the tube; calyx, 1 in. long, bright green; corolla  $2\frac{1}{2}$ -3 in. diam.—One of the finest and most floriferous shrubs for a warm greenhouse or subtropical country, of

extremely easy cult., and readily trained into fine specimens. Readily conforms to pot culture. Should be kept slightly on the dry side during the winter, but not enough to cause it to lose the lvs.

**ramosissima**, Benth. Lvs. oblong to nearly lanceolate, acuminate or obtuse, glabrous or rarely slightly hairy above and hairy or villous beneath: fls. large, in lax cymes, deep violet-purple, the corolla-tube twice longer than the calyx.—One of the best, with luxuriant foliage; may be grown cooler in winter than the other species. Probably a form of *B. calycina*.

**Hopeana**, Benth. (*Franciscea Hopeana*, Hook. *F. uniflora*, Pohl). A slender twiggy free-branching shrub: lvs. lanceolate-oblong, thin in texture, rich dark green, paler beneath: fls. small but freely produced, solitary or in pairs all along the leafy growths; limb light violet-blue on first opening, fading to almost pure white with age; tube very slender, curved upwards, nearly white, 1 in. long; calyx  $\frac{3}{4}$  in. long, teeth obtuse. Brazil. W. Indies. B.M. 2829. L.B.C. 14:1332.

**latifolia**, Benth. (*Franciscea latifolia*, Hook.). Habit dwarf with slender spreading branches: lvs. elliptic, 2–4 in. long, acute or obtuse, glabrous above, slightly pubescent beneath: fls. in terminal clusters or short axillary, few-fl. cymes; corolla  $1\frac{1}{2}$  in. diam., pale violet, with white center, changing in a day or so to white, sweetly scented; tube  $1\frac{1}{2}$  in. long, slender, slightly curved; calyx erect, campanulate,  $\frac{1}{2}$  in. long, teeth acute. Trop. Amer. B.M. 3907.

AA. Fls. white or yellow.

**americana**, Linn. Habit dwarf, branches slender: lvs. glabrous or nearly so; lamina elliptic-ovate, acute; petiole  $\frac{1}{2}$ –1 in. long, stout: fls. solitary and axillary, or in terminal few-fl. clusters, pure white shading with age to pure yellow and sweetly scented, especially at night; petals obtuse; calyx green, campanulate teeth spreading, nearly equaling the length of the tube. Trop. Amer. B.M. 393.—Of very easy cult., and thriving and seeding freely under the conditions of an ordinary greenhouse. In Fla., grows 4–6 ft. high; the very fragrant fls. are much prized.

Var. **pubescens** (*A. fallax*, Hort.). Resembles the type, but hairy in all its parts, and rather more floriferous.

**undulata**, Swartz. A strong-growing evergreen shrub or small tree, reaching to 20 ft. in its native habitat and flowering freely when quite small: lvs. ovate-lanceolate, margins slightly wavy, light green in color, acute, variable in size up to 7 in. long and 2 in. wide when vigorous; apex acute or obtuse; petiole  $\frac{1}{4}$ – $\frac{1}{2}$

in. long: fls. on the upper parts of the sts. solitary or in pairs in the axils of most of the terminal lvs. forming terminal clusters; calyx cyme green  $\frac{1}{2}$ – $\frac{3}{4}$  in. long, campanulate; corolla white changing to creamy white with age; lobes broadly ovate or orbicular in outline and with beautiful wavy margins. Jamaica. B. M. 8422.—A magnificent free-flowering species and a great acquisition to any garden. Requires subtropical conditions.

67. *Brunfelsia calycina* var. *macrantha*. ( $\times \frac{1}{2}$ )

**jamaicensis**, Griseb. (*B. nitida* var. *jamaicensis*, Hook.). An erect shrub or small tree, sparsely branched in the young state: sts. woody, with the lvs. more or less tufted at the ends of each year's growths: lvs. elliptic or lanceolate, up to 7 in. long, but often small and borne on short lateral tufted growths, glabrous or nearly so; petiole very short: fls. crowded on the apex of the current year's growth, solitary (occasionally in pairs) and axillary; pedicels  $\frac{1}{4}$ – $\frac{1}{2}$  in. long, slender, erect or spreading; calyx erect,  $\frac{1}{2}$  in. long, campanulate teeth spreading, acute; corolla erect, white, changing with age to primrose-yellow. W. Indies. B.M. 4287.—A very fine species for the warmer parts of the S., but a somewhat shy-flowering plant unless the growth is thoroughly well ripened up. There is a general resemblance between this species and *B. nitida* and *B. undulata* and it is possible that they are forms of one polymorphic species.

L. H. B.  
C. P. RAFFILL.

**BRUNSDÓNNA**. A cross between *Brunsvigia* and *Amaryllis Belladonna* has recently been given the garden name *Brunsdonna Sanderæ alba*; it has the umbel resembling typical *A. Belladonna*, and one-sided rather than globular: fls. white. See *Amaryllis Belladonna* var. *Parkeri*, which is a similar cross.

**BRUNSVÍGIA** (after the Duke of Brunswick). *Amaryllidaceæ*. Tender summer- or autumn-flowering bulbs.

Umbels of large numerous brick-red fls.; corolla funnelliformed, 6-parted, deciduous, its segms. nearly equal, recurved at the tip.—Species 9. S. Afr.

The bulbs must be thoroughly rested from the time the leaves fade until the scape appears. *Brunsvigias* are hard to flower. They require rich, sandy soil, plenty of heat and sunlight. When growing, give water and liquid manure freely. They propagate by offsets. For fuller instructions, see *Amaryllis*.

AA. Lvs. strap-shaped.

**Josephinæ**, Ker. Bulb 5–6 in. thick: lvs. 8–10, strap-shaped, glaucous or greenish, thick, closely ribbed, 2–3 ft. long,  $1\frac{1}{2}$ –2 in. broad: scape 1 in. thick,  $1\frac{1}{2}$  ft. long; fls. 20–30, rarely 50–60, in an umbel; pedicels  $\frac{1}{2}$ –1 ft. long: caps. smaller than in *B. gigantea*, less conical and less strongly angled. B.M. 2578. F.S. 4:322.—Named after the Empress Josephine, who purchased the original bulb after it flowered at Malmaison.

AA. Lvs. tongue-shaped.

**gigantæa**, Heist. (*Amaryllis gigantæa*, Van Marum. *A. orientalis*, Ecklon). Bulb very large: lvs. about 4, tongue-shaped, closely ribbed, 3–5 in. broad, usually under 1 ft. long: scape red or green, a finger's thickness; fls. 20–30 in an umbel, paler than in *B. gigantea*, and less numerous; pedicels stout, strongly ribbed, 4–6 in. long. B.M. 1619 (as *B. multiflora*).

*B. falcata*, Ker.—*Ammocharis falcata*.—*B. magnifica*, Lind. Fls. 20–25 in a cluster; corolla short; the segms. white, with medium stripe of red or purplish red: lvs. 1–2 ft. long, 3–3½ in. wide, recumbent.—Thought by Baker to be *Crinum Forbesianum* or near that species.

N. TAYLOR.†

**BRUSSELS SPROUTS**. Fig. 672. A form of the cabbage tribe, grown for the globular buds or "sprouts" produced along the stout upright stem.

The garden varieties of brussels sprouts represent one of the many interesting variations that have taken place in the cabbage family. This plant, while in its seedling stage and during its early life, closely resembles the ordinary cabbage, but later in its development the axillary buds, instead of remaining dormant as is the case with the common cabbage, develop into miniature heads similar in their make-up to an ordinary head of cabbage but very small.

The soil to which the sprout is adapted is, in general, the same as that for late cabbage; in fact, the plant is

always grown in conditions similar to those chosen for late cauliflower or late cabbage, and its range of adaptation is much the same as that of autumn cabbage. The fertilizing of the crop should be the same, in general, as for autumn cabbage. The plants should be set so as to allow them sufficient room for full development, preferably in check-rows 30 to 36 inches apart each way. Young seedlings should be ready for planting in the latitude of New York from June 20 to July 10. The cultivation of the crop, up to the time the sprouts begin to develop, is practically the same as that for cabbage.

The enemies and diseases to which brussels sprouts is subject are the same as those of the fall crops of other cabbage-like plants. Aphis, green-worm, the harlequin-bug and the cutworm are probably the most annoying of the insect pests, while the rots, damping-off fungus and the mildew are more or less troublesome.

Before the sprouts are ready for harvest, the lower leaves of the plants are broken away in order to facilitate the cutting of the miniature heads or sprouts; this is done by means of a sharp short-bladed knife, used to separate them from the stalk of the plant. In sections in which the plant can remain in the open during the winter, two or three cuttings are made. The first sprouts develop in the axils of the leaves nearest the ground, and as the stalk of the plant elongates and more leaves are added, a succession of sprouts develop. The first cutting is confined, therefore, to the older and more fully developed sprouts. When the miniature heads have attained the size of  $\frac{1}{2}$  to 1 inch in diameter, the cutting begins and is repeated at intervals depending upon the development of the sprouts. In regions in which it is not safe to allow the plants to remain in the open during the winter, a small supply for home use or for local market may be stored in a vegetable-cellar or storage-pit, the plants being lifted with earth adhering to the roots and planted in sand that is kept somewhat moist during the storage period. Under these conditions, the sprouts will remain in good condition for several weeks and successive harvests can be made the same as when the plants are standing in the open.

The hand labor involved in gathering the sprouts and preparing them for market is the chief deterrent to the extensive cultivation of this crop. It is only in regions in which mild winter conditions prevail and in which labor is available to harvest and assort the sprouts that the industry thrives on a commercial scale. After the sprouts have been cut and placed in suitable receptacles, they are carried to a packing-house where each head is trimmed by removing the outer leaves. The trimmed heads are then placed in berry boxes holding one quart, those for the top layer being selected for uniformity in size and arranged so as to give a finished appearance to the receptacle.

Several varieties of brussels sprouts are offered by the trade, but there is only one general type, the chief difference being in the length of the stalk of the plant itself and the manner in which the sprouts are distributed along the stalk. This plant, although a popular vegetable in England and on the Continent, is sparingly cultivated in the United States, a few centers only giving attention to it as a commercial crop. Parts of Long Island, in New York, are well known for brussels sprouts production.

L. C. CORBETT.

672. Brussels Sprouts.

**BRYÁNTHUS** (Greek, *bryon*, moss, and *anithos*, flower: growing among mosses). *Ericaceæ*. Heath-like low shrub with pretty pink flowers, suitable for rockeries, but not yet in cultivation.

Leaves evergreen, linear, remotely denticulate: calyx 4-parted; corolla rotate, 4-parted; stamens 8: caps. subglobose, 4-valved.—One species on Kamtchatka and Behrings Isls. The genus *Phyllodoce* has been referred by several botanists to *Bryanthus*, but it differs considerably in its urceolate or campanulate 5-lobed corolla, 10 stamens, 5-valved caps. and solitary or umbellate fls.

This prostrate evergreen shrub has small needle-shaped leaves and small rosy pink flowers in peduncled, slender, 3-10-flowered racemes. *Bryanthus* will probably require the same treatment as *Chiogenes*, *Loiseluria* and *Phyllodoce*. The only species is *B. Gmelinii*, Don. For illustration, see Pallas, Fl. Ross. 2:74 (as *Andromeda Bryanthus*).

*B. Brèweri*, Gray=*Phyllodoce Brèweri*.—*B. empetriformis*, Gray=*Phyllodoce empetriformis*.—*B. erectus*, Lindl.=*Phyllodoce erecta*.—*B. glanduliflorus*, Gray=*Phyllodoce glanduliflorus*.—*B. taxifolia*, Gray=*Phyllodoce taxifolia*.

ALFRED REHDER.

**BRYÒNIA** (Greek, *to sprout*, referring to the annual growth from the tuber). *Cucurbitaceæ*. Herbaceous perennial climbers.

A genus of 12 species of perennial cucurbits, native of Eu. and W. Asia. They are herbaceous from a tuberous root, with staminate fls. in racemes, while *Bryonopsis* is an annual plant, with the staminate fls. in fascicles. All species of *Bryonia* are dioecious except *B. alba*. *Bryonopsis* is monoecious. See Cogniaux, in DC. Mon. Phan. 2:469.

A. Fls. *diæcios*; *stigmas rough*: fr. red.

**diðica**, Jacq. **BRYONY**. Height 6-12 ft.: root long, fleshy, branching, white, a finger's thickness: lvs. ovate or roundish in outline, 5-lobed, margin wavy-toothed, rough with callous points, paler beneath: pistillate fls. greenish white, corymbose, short-peduncled.—Common in England and in Cent. and S. Eu., rarer in W. Asia and N. Afr. Not usually sold in Amer., but a common plant along English highways and cult. in American botanic gardens. It grows rapidly over hedges and fences. Root of this and of *B. alba* are employed principally as a hydragogue-cathartic. The fresh, bruised root applied to the skin causes vesication.

AA. Fls. *monæcios*; *stigmas smooth*: fr. black.

**álba**, Linn. Height 6-12 ft.: roots thick, tuberculate, yellowish outside, white within: lvs. long-petioled: pistillate fls. in long-peduncled racemose corymbs. Eu., Caucasus, Persia.

*B. laciniosa*, Linn.=*Bryonopsis laciniosa*.

WILHELM MILLER.

**BRYONÓPSIS** (Greek, *Bryony-like*). *Cucurbitaceæ*. A genus of two species of annual climbers. Consult *Bryonia* for generic differences.

**laciniosa**, Naudin (*Bryonia laciniosa*, Linn.). Lvs. deeply 5-lobed, rough, light green above, paler beneath; segms. oblong-lanceolate, acuminate, serrate: fls. monoecious, fascicled or solitary, yellow: fr. about the size of a cherry, spherical, green, with pretty white markings. Asia, Afr., Austral. F.S. 12:1202. Var. **erythrocarpa**, Naudin (*B. erythrocarpa*, Naudin). Has red fr. with white marks. I.H. 12:431. F.S. 21:2237. Gn. 6, p. 193.—A warmhouse plant, rarely grown in pots and trained to rafters. Prop. by seeds.

WILHELM MILLER.

**BRYOPHYLLUM** (Greek, *sprouting leaf*). *Crasulaceæ*. A small genus of succulent plants in the same order with stonecrops, hen-and-chickens, cotyledon and echeveria, grown to some extent as flowering plants but more especially as a foliage novelty.

Root-system fibrous and very abundant: sts. upright,

simple or sometimes branching toward the base, of a thick soft tissue over a woody cylindrical core: lvs. opposite, petioled, simple or pinnately compound, succulent: infl. cymose or paniculate; fls. nodding; sepals 4, united into an inflated calyx which incloses the lower half or more of the corolla; corolla cylindrical, ending in 4 petal tips; stamens 8; ovaries 4, separate or more or less united below.

The members of this genus may readily be distinguished from related genera by the "sprouting" habit of their leaves as indicated by the generic name. If a leaf is removed from a plant and placed in a warm moist place, young plants will very soon appear in the notches around its border. This is the simplest method of propagation and is usually accomplished by placing the leaf flat on the wet sand of a growing-bench, in a warm, sunny exposure. Tiny buds will soon appear in the notches and these are followed by numerous fine roots. See Fig. 673. When the small plants have attained a size sufficiently large to be handled, they may be removed from the parent leaf and potted. This method may be employed in growing-houses at any season. Plants are also readily produced from stem-cuttings rooted in sand, or from seed. Seeds retain their vitality more than a year when kept dry. The best plants are to be grown by using rather rich loose, well-drained soil, with plenty of light, heat and moisture. However, they are very tenacious of life and will survive with a minimum of water and a low, but not freezing, temperature. They grow luxuriantly out-of-doors during the summer months but must be housed during the frost period. Useful in various botanical demonstrations.

**pinnatum**, Kurz (*B. calycinum*, Salisb.). Figs. 673-4. Height 2-4 ft.: lvs. opposite, fleshy, becoming leathery with age, earlier ones simple, ovate, with cordate or rounded base, later ones pinnate and then of 3-5 short-stalked lfts., the rachis and petiole with a narrow groove on the upper side, margin crenately doubly-serrate, light green becoming purplish along the veins toward maturity, margin purple as are also the petioles and young st.-growths: fls. pendulous, in terminal panicles; calyx much inflated, purplish green with lighter dots,  $1\frac{1}{2}$  in. long; corolla greenish white with purple-tinted, spreading acute tips. Tropics of both hemispheres. B.M. 1409. L.B.C. 9:877. G.C. III. 41:422. J.H. III. 46:205.

673. Sprouting leaf of Bryophyllum.

R.B. 24:125. R.H. 1900, p. 362. V. 3:117; 4:113; 7:340.—Said to be used in India as a diuretic.

**crenatum**, Baker. Less robust in habit of growth than the preceding: height 2-3 ft.: lvs. very fleshy, simple, 1-3 in. long, becoming smaller upward on the st., ovate with rounded or cordate base, in the latter case strongly crested auriculate, margin coarsely crenate to dentate, bright green with purplish pink margin and strongly bluish glaucous when young as are also the petioles and

sts.; petioles not grooved on the upper side: fls. nodding, in terminal, open, corymbose cymes; calyx membranaceous, inflated,  $\frac{3}{8}$  in. long, pink; corolla  $\frac{3}{4}$  in. long, ending in 4 rounded segms., red. Madagascar. B.M. 7856. G.C. III. 33:59; 41:419. G.W. 10, p. 396; 6, p. 495. R.H. 1900, pp. 175, 176, 362.

*B. proliferum*, Bowie. Occasionally met with, is much more robust in growth, reaching 12 ft. in height: st. 4-angled in new growth, becoming cylindrical later: lvs. pinnatifid to pinnate, the base of the pinnæ very much thickened, blade much contorted and margin finely crenate, rachis and petiole prominently grooved on the upper side. S. Afr. B.M. 5147. F.S. 23:2446.—Of little value more than a novelty.

C. H. THOMPSON.

BUCKEYE: *Esculus*.

**BUCKLEYA** (after S. B. Buckley, American botanist, died in 1884 at Austin, Texas). *Santalaceæ*. Shrubs rarely introduced in botanical collections, without particular ornamental qualities, but interesting as one of the few parasitic shrubs successfully introduced into cultivation.

Leaves opposite, sessile, entire: fls. dioecious, apetalous; staminate in umbels, with 4 short ovate sepals and 4 short stamens; pistillate solitary, terminal, with 4 short deciduous sepals and below with 4 elongated linear-lanceolate persistent bracts; calyx-tube clavate; style short with 2-4-parted stigma; ovules 3-4: fr. a furrowed drupe.—Three species in China and Japan and 2 in N. Amer.

Only the American species, *B. distichophylla*, Torr., is in cult. A slender-branched upright shrub, to 12 ft.: lvs. 2-ranked, ovate-lanceolate or ovate, 1-2½ in. long, acuminate, ciliate: fls. small, greenish: fr. an ovoid or oblong-ovoid yellowish green drupe, about 1 in. long, crowned by the 4 persistent bracts. N. C. and Tenn. G.F. 3:237.—Parasitic on the roots of *Tsuga*. Has proved perfectly hardy in Mass.: there is a plant about 70 years old in the botanic garden at Cambridge. It has also been successfully cult. at the Arnold Arboretum and in a few European botanic gardens. Prop. by seeds; best sown with a potted *Tsuga* in the greenhouse and planted out with its host when the young plants are strong enough, preferably within the reach of the roots of a large *Tsuga*, in order that the original host may be removed later when it crowds the young buckleya too much.

ALFRED REHDER.

**BUCKTHORN**: *Rhamnus*, particularly *R. catharticus*; also *Bumelia*.

**BUCKWHEAT** (*Fagopyrum esculentum*, Moench). *Polygonaceæ*. A tender annual grain plant, flour being made of the large 3-cornered fr. It is much grown in the N. U. S., usually being sown about the first of July. It is also a favorite for bee forage. Buckwheat is native to Cent. Siberia and Manchuria, and is now widely cult., although it is a grain of secondary importance. The Tartarian buckwheat (*F. tataricum*, Gaertn.) is occasionally seen. It has smaller and yellowish fls., and a smaller roughish, wavy-angled fr. This species is often confounded with forms of *F. esculentum*, from which it is really easily distinguished. Buckwheat is a good cleaning crop for weedy and hard lands. For general discussion of buckwheat, consult Cyclo. Amer. Agric.. Vol. II. See *Fagopyrum*.

BUDDING: *Graftape*.

674.

Flowers of *Bryophyllum pinnatum*. ( $\times \frac{1}{2}$ )

**BUDDLEIA** (after Adam Buddle, an English botanist). Syn., *Buddleia*. *Loganiaceae*. Ornamental shrubs or trees, chiefly grown for their handsome flowers profusely produced in showy panicles or globular heads.

Woody plants or rarely herbs, more or less covered with a stellate, glandular or scaly pubescence: lvs. opposite, short-petioled, entire or serrate: fls. in racemes, panicles or clusters; corolla tubular or campanulate, 4-lobed; stamens included, 4: fr. a 2-celled caps. with numerous minute seeds.—About 70 species in tropical and temperate regions of Amer., Asia and S. Afr., of which only a small number of hardier species is cult.

The buddleias are deciduous or sometimes half-evergreen trees or shrubs with usually quadrangular branches, narrow rather large leaves and small lilac, violet, white or yellow flowers in showy panicles or clusters. None of the species is hardy North, but some, as *B. japonica*, *B. Davidii*, *B. Lindleyana* and *B. intermedia* will live through the winter, if protected with dry leaves around the base; even if the stems are killed nearly to the ground, they will freely push forth young shoots in spring, which usually flower the same year. The handsomest in flower are *B. Colvillei*, *B. Davidii*, *B. asiatica*, *B. globosa* and *B. officinalis*.

They grow best in a rich, well-drained soil, in a sunny position; they are rather coarse plants and need much space. Propagation is readily effected by seeds sown in spring in gentle bottom heat, by greenwood cuttings under glass, or by hardwood cuttings taken off in fall and kept during the winter in a frost-proof room.

## INDEX.

asiatica, 7.	intermedia, 2.	officinalis, 5.
capitata, 9.	japonica, 1.	salicifolia, 3.
Colvillei, 10.	Lindleyana, 3.	sinuato-dentata, 3.
curviflora, 1.	macrostachya, 6.	superba, 4.
Davidii, 4.	madagascariensis, 8.	variabilis, 4.
globosa, 9.	magnifica, 4.	Veitchiana, 4.
heterophylla, 8.	neemda, 7.	Wilsonii, 4.
insignis, 2.	nivea, 6.	yunnanensis, 6.

A. Corolla small, with long, narrow tube,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long.

B. Fls. in panicles.

C. Color violet or lilac.

D. Lvs. glabrous or only slightly grayish tomentose beneath: stamens inserted below the middle of the tube.

1. *japonica*, Hemsl. (*B. curviflora*, André, not Hook. & Arn.). Three to 6 ft., with spreading quadrangular, winged branches: lvs. ovate-lanceolate, acuminate, remotely denticulate or coarsely dentate, slightly tomentose or nearly glabrous beneath, 3–6 in. long: fls. in dense, terminal, pendulous racemes, 4–8 in. long; corolla slightly curved, lilac with grayish tomentum outside. Japan. I.H. 17:25. R.H. 1870, p. 337; 1878, p. 330.

2. *intermedia*, Carr. (*B. japonica* × *B. Lindleyana*). Hybrid of garden origin, similar in habit to *B. japonica*. Lvs. ovate-oblong, dark green above, 4–5 in. long: fls. violet, in slender, arching or pendulous racemes, 10–20 in. long. R.H. 1873:151. Var. *insignis*, Rehd. (*B. insignis*, Carr.), has the upright habit of *B. Lindleyana*. Branches distinctly winged: lvs. oblong-lanceolate, often in 3's: racemes erect, rather dense, 4–6 in. long, usually panicle at the end of the branches, with rosy violet fls. R.H. 1878:330.

3. *Lindleyana*, Fort. (*B. salicifolia*, Hort., not Jacq.). Three to 6 ft.: lvs. ovate or oblong-lanceolate, acuminate, remotely denticulate, pale green beneath, and slightly pubescent or glabrous, 2–4 in. long: racemes dense, erect, 3–5 in. long; corolla purplish violet, slightly curved, pubescent outside. China. B.R. 32:4. F.S.

2:112. P.M. 14:5. R.H. 1846:201. Var. *sinuato-dentata*, Hemsl. Lvs. sinuately-dentate. China.

DD. Lvs. densely white or yellowish tomentose beneath: stamens inserted slightly above the middle.

E. *Tomentum close*.

4. *Davidii*, Franch. (*B. variabilis*, Hemsl.). Fig. 675. Three to 8 ft.: lvs. nearly sessile, ovate-lanceolate or lanceolate, acuminate, coarsely serrate, whitish-tomentose beneath, 4–10 in. long: fls. in dense, terminal, erect or nodding panicles, 4–6 in. long or in some varieties longer; corolla lilac, with orange-yellow mouth, glabrous outside. Aug., Sept. China. B.M. 7606. R.H. 1898:132; 1902, p. 383. G.C. III. 24:139. Gn. 55:428; 64, p. 153. M.D.G. 1908:136.—A very handsome species with showy and fragrant fls. appearing in great profusion in late summer; several varieties differing from the type which has rather lax panicles of lilac-purple fls. with an orange eye not very marked, by larger and denser panicles and brighter color. Var. *Veitchiana*, Rehd. (*B. variabilis* var. *Veitchiana*, Hort.). More robust, erect at first, later gracefully arching, with denser and larger clusters of bright mauve-colored fls. with a bright orange eye; begins to bloom early in Aug. J.H.S. 27:182. J.H. III. 45:381. G.M. 51:45. G.W. 16, p. 538. Var. *magnifica*, Rehd. & Wilson (*B. variabilis* var. *magnifica*, Wilson). Similar to the preceding: has larger deep rose-purple fls. with deep orange eye and the margin of the petals reflexed, panicles very dense; begins to bloom about the middle of Aug. Gn. 68, p. 161; 69:288. R.B. 33:281. F.S.R. 3, p. 339. G.M. 52:668. Var. *superba*, Rehd. & Wilson (*B. variabilis* var. *superba*, DeCorte). Color of fls. like the preceding variety but petals not reflexed at the margin and panicles larger. R.B. 35:12. Var. *Wilsonii*, Rehd. & Wilson (*B. variabilis* var. *Wilsonii*, Hort.). Tall and arching, with longer and narrower lvs.: panicles drooping, rather loose, sometimes attaining 30 in. length; corolla smaller, bright rose-lilac with bright orange eye; corolla-lobes half upright and reflexed at the margin: in full bloom through Sept., the latest of all. There are also other named varieties.

5. *officinalis*, Maxim. Shrub, to 8 ft.: branchlets nearly terete, grayish tomentose: lvs. oblong to linear-lanceolate, 2–6 in. long, entire or serrulate, grayish pubescent above, whitish or fulvous tomentose beneath: fls. lilac with orange eye, fragrant, in terminal panicles usually 4–6 in. long, consisting of short-peduncled dense clusters; corolla over  $\frac{1}{2}$  in. long with a slender tube pubescent outside and within and twice as long as the oval obtuse lobes. W. China. B.M. 8401. G.C. III. 49:200.—Tender; flowers during the winter in the greenhouse like *B. asiatica*. Page 3566.

EE. *Tomentum fluffy, white or yellowish: stamens inserted just below the mouth*.

6. *nivea*, Duthie. Shrub, to 8 ft.: branchlets, the under side of the lvs. and infl. densely covered with a pure white woolly tomentum: lvs. ovate-lanceolate, 4–9 in. long, acuminate, coarsely serrate, glabrous above: fls. lilac or purple, small, in long terminal panicles; corolla with the tube tomentose outside, glabrous within except at the mouth. Aug., Sept. W. China. G.C. III. 38:275.—Very distinct on account of its white fluffy tomentum, but fls. less showy than in most other species, nearly embedded in the fluffy tomentum of the infl. Tender. Var. *yunnanensis*, Rehd. & Wilson (*B. macrostachya* var. *yunnanensis*, Dop). *Tomentum* less fluffy, yellowish: lvs. pubescent above: fls. larger; panicles usually solitary. W. China.

cc. *Color white: stamens inserted just above the middle of the corolla.*

7. *asiatica*, Lour. (*B. neêmda*, Roxbg.). Shrub or small tree: branchlets terete with white or buff-colored tomentum when young: lvs. lanceolate, 4-8 in. long, acuminate, entire or serrulate, glabrous above, white or buff tomentose beneath: fls. white, very fragrant, in slender drooping panicles, 3-6 in. long and usually several at the end of the branchlets; corolla with the tube villous outside and spreading suborbicular erose lobes or in a less desirable form with ovate, erect and entire lobes. Jan., Feb. China, India, Java. B.M. 6323. G.C. III. 39:106. Gn. 69, p. 89; 76, p. 80. J.H. III. 52:180. G.W. 10, p. 502.—A very desirable greenhouse shrub on account of its slender spikes of deliciously fragrant white fls. in winter. If prop. early in spring, transplanted several times or planted out during the summer, the plants will be of sufficient size in autumn to flower the following winter.

ccc. *Color yellow.*

8. *madagascariensis*, Lam. (*B. heterophylla*, Lindl.). Straggling shrub, 6-20 ft., with densely tomentose branchlets: lvs. ovate-oblong, rounded or slightly cordate at the base, acuminate, entire, dark green and lustrous above, whitish or yellowish tomentose beneath: fls. tomentose outside, in large terminal panicles, appearing during the winter. Madagascar. B.R. 15:1259. B.M. 2324.—Hardy only in subtropical regions. Sometimes cult. in Calif. and used as a half-climbing plant to cover unsightly objects.

BB. *Fls. in globular heads.*

9. *globosa*, Lam. (*B. capitata*, Jacq.). Three to 10 ft. with the branches and lvs. beneath yellowish tomentose: lvs. ovate or ovate-lanceolate, acuminate, crenate, rugose above, 3-7 in. long: fls. orange-yellow, in dense, long-peduncled, axillary heads at the ends of the branches, fragrant. Chile. B.M. 174. Gn. 33, p. 369. G. 28:505. G.M. 53:979. F.S.R. 3:335 (habit).—A graceful and very distinct shrub, standing some degrees of frost.

AA. *Corolla with broad cylindrical tube, limb over 1 in. broad.*

10. *Côlvillei*, Hook. & Thoms. Shrub, occasionally tree, to 30 ft.: lvs. elliptic-lanceolate or lanceolate, serrate, pubescent, and pale or grayish green beneath, 5-7 in. long: panicles broad, pendulous, 12-18 in. long; corolla purple or crimson, with white mouth. B.M. 7449. R.H. 1893:520. I.H. 41:10. F.S. 14:1487. J.H. III. 31:85.—The most beautiful of all buddleias, and a very desirable shrub for warmer temperate regions; only older plants flower freely.

*B. albiflora*, Hemsl. (*B. Hemsleyana*, Koehne). Allied to *B. variabilis*. Shrub or small tree, to 30 ft.: lvs. lanceolate, 5-9 in. long, glabrous above, white or yellowish tomentose beneath: fls. small, lilac, in elongated spikes, sometimes to 20 in. long. W. China. G. 27:501.—Less handsome than *B. variabilis*: fls. not white, as the name implies, given under the impression that the fls. were white.—*B. americana*, Linn. Shrub, 8-12 ft.: lvs. ovate to oblong-lanceolate, cuneate at the base, glabrous above, yellowish tomentose beneath, 4-10 in.: fls. in terminal densely tomentose panicles consisting of sessile subglobose clusters. Mex. to Peru.—*B. auriculata*, Benth. Straggling shrub: petioles auriculate; lvs. oblong-lanceolate, entire or denticulate, grayish white tomentose below, 1½-3 in. long: fls. cream-colored, fragrant, tomentose outside, in terminal compact panicles; stamens above the middle. S. Afr. G.C. II. 16:633; III. 6:529. I.T. 1:20. Tender.—*B. brasiliensis*, Jacq. f. Upright shrub: sts. quadrangular: lvs. ovate to oblong-deltoid, crenate-serrate, white-tomentose below, 4-8 in. long, decurrent into the winged auriculate petiole; fls. orange-yellow, pubescent outside, in axillary clusters, forming terminal narrow panicles; stamens just below the mouth. Mex. to Brazil. B.M. 2713. Tender.—*B. columbica*, André. Upright shrub, similar to *B. Lindleyana*. Lvs. narrow-lanceolate, entire, 4-8 in. long, glabrous: fls. white in terminal slender panicles; corolla with spreading lobes slightly shorter than the corolla-tube. Spring. Of unknown origin. R.H. 1901, p. 37. Tender.—*B. crispa*, Benth.—*B. paniculata*, Wall. (*B. Hemsleyana*, Koehne)—*B. albiflora*.—*B. paniculata*, Wall. (B. *crispa*, Benth.). 6-15 ft.: fls. lilac, in rather dense panicles; branches and lvs. tomentose. B.M. 4793. F.S. 9:958.—*B. pulchella*, N. E. Br. Shrub, 2 ft.: branchlets terete, tomentose: lvs. hastate, irreg-

ularly lobed, or rhomboid to lanceolate, 1-2 in. long, pubescent: fls. white with orange eye, fragrant, in terminal panicles, 2-2½ in. long; corolla with slender tube, pubescent outside. S. Afr. (?)—*B. salicifolia*, Jacq.—*Chilanthus arboreus*.—*B. saligna*, Willd.—*Chilanthus arboreus*.—*B. stenostachya*, Rehd. & Wilson. Allied to *B. nivea*. Less fluffy: lvs. oblong-lanceolate: panicles usually 3, long and slender; fls. larger, anthers inserted above the middle of the tube. W. China.

ALFRED REHDER.

**BUDS.** A bud is an incipient shoot or short growth-axis concealed by the closely investing leaves, or leaf-parts, that it bears. The foliage-shoots and flower-shoots of all seed plants arise from buds. The leaves converge over the true stem-apex or growing-point. The essential thing is that this growing-point continues the terminal growth and gives rise laterally, behind the point, to new leaves, in the axils of which buds may be formed ultimately. In the plumule of the seed the first bud activity is manifest, and thenceforth a bud marks every growing stem-apex.

676. Apple buds—fruit-bud on the left, leaf-bud on the right.

has a more or less equal work as a part of the bud. As the apex elongates and each leaf develops, greater growth on the inner (upper) surface effects its complete exfoliation. Using favorable material, one may completely dissect the bud, laying bare the growing-point, which may be readily examined with a hand-lens. Either of the little pondweeds commonly cultivated, *Elodea* or *Hippuris*, may be used for this purpose.

The buds which are commonly most conspicuous and at the same time most highly specialized are the "resting" buds of temperate shrubs and trees. Such buds are often scaly buds, and they are characteristic of all climates in which there is an interruption to growth, either through cold or dryness. In this case the stem-apex and younger leaves are normally inclosed by persistent more or less indurated leaf-parts modified as bud-scales. Resinous secretions may accompany the scales and the younger leaves may be covered with hairs. The size, form and minute characters of such buds vary widely, but obviously they are, in general, wondrously efficient in the resistance exhibited towards rigorous climatic conditions. The important point is that the bud-structures quite effectually prevent drying out of the young shoot which is there tucked away.

Particularly interesting is the fact that the resting-bud of many trees includes in miniature the entire vegetative or flowering shoot of the next season. In such case the rapid elongation of the axis and unfolding of leaves in the spring is soon followed by the formation of a new resting-bud wherein the shoot of another year is gradually differentiated. Every gradation occurs between this type and the typical active bud of annuals.

677. Pear twigs—fruit-buds on the left leaf-buds on the right.

Interest in buds centers in their spring activity, properly in the awakening and growth resulting when the conditions have remained favorable sufficiently long. Leaves and axes enlarge and elongate rapidly, bursting asunder the dead scales and often carrying forward the expanding younger ones. The growth of

the younger scales exhibits the true nature of these structures, some of which are found to be leaf petioles; some petioles with minute blades; and various other modifications occur. Many resting-buds are awakened from their comparative inactivity by a few days of favorable weather. These are "early" flowers, and of this type are the lilac and the golden bell. Other buds require a longer period, such as the oak and the hick-

ory. It is not strange, therefore, that some plants lend themselves readily to early forcing by etherization, the hot water treatment, and the like, while others are with great difficulty forced.

In the preceding, more specific mention has been made of buds which develop leafy shoots, that is of leaf-buds. It is clear, however, that the resting-bud, as well as an herbaceous bud, may develop a single flower, as in the peach; a cluster of flowers, as in the red maple; or a shoot with leaves and flowers, as in the apple and Norway maple. The occurrence of leaf- and flower-buds with respect to the age of the twig and the relation of pruning to bud disposition are questions of special horticultural interest, but cannot receive consideration in this brief account. Illustrations of flower-buds and leaf-buds are shown in Figs. 676-679.

Buds are normally produced terminally and in the axes of leaves, the latter arrangement therefore corresponding to leaves; but under exceptional circumstances they may arise from the growing tissue of any member. Buds from the roots of the sweet potato and dahlia are important in propagation; likewise are those produced by the leaves of certain species of Begonia. As a matter of fact, buds originating from internodes, roots and leaves—so-called regenerative-buds—are not uncommon; but the development in such situations occurs as a rule only when normal buds are not present.

Buds with the leaves and leaf-parts surrounding them are sometimes organs of food-accumulation. The typical bulb is little more than a fleshy bud, and there are all gradations between the typical bulb and the typical tuber—the latter with many buds. Small bulb-like buds occur in *Lilium bulbiferum* and a few other plants, and they are always important in propagation. It requires no stretch of the imagination to classify the edible shoots of brussels sprouts among unusual buds, and from this it is no great leap to the monstrous "bud" of the cabbage.

toba and Saskatchewan south to Colorado, Nevada and New Mexico, now grown in the upper Mississippi Valley and northward for its abundant acid fruits.

The buffalo berry was brought into use early, mention being made in Hovey's Magazine of Horticulture for 1841, page 251, of its being frequently cultivated. It is a handsome ornamental shrub, with silvery foliage and red berries. Occasional plants are found with yellow fruit. The plant is dioecious; therefore, care should be taken, if fruit is desired, to plant both staminate and pistillate plants. Western nurserymen are beginning to offer these two kinds of plants separately in the ratio of one staminate to four pistillate plants, but the best proportion is not yet known. Many persons who plant the buffalo berry are disappointed by securing only one sex. The staminate or male plants may be known in their winter condition by the dense clusters of rounded flower-buds; the pistillate or female plants by the smaller, flattened, fewer, more slender flower-buds.

The fruit varies greatly in size, quality and season, and is gathered in large quantities for culinary use. It makes a delicious jelly. Some berries are of sprightly flavor, good for eating out of hand. They can also be dried for winter use. The fruit is generally considered better when touched by frost, less sugar being required. The name is said to have come from the custom of eating the berries as a sauce with buffalo meat in the early days. The buffalo berry makes a fine thorny hedge, that is both useful and ornamental.

It is found that sprouts received as dug up in the native thickets from various parts of the Northwest do not always transplant satisfactorily; a year in a nursery row gives them better roots and secures an

679.

Buds of the peach. The middle bud is a leaf-bud and the large side buds are fruit-buds.

even stand when set in their permanent place. Seedlings are better rooted. Seedlings are easily raised from seed washed free from the pulp in the fall and stratified for winter, keeping in sand in a box buried just beneath the surface in a well-drained spot in the garden. There should be holes in the box for free drainage and the planting should be done very early in the spring. In Bulletin No. 88, June, 1904, of the South Dakota Experiment Station, Plate 19 shows a field of 7,500 buffalo berry plants of the first generation under cultivation. These plants were raised from seed gathered along the Missouri River of South Dakota, where buffalo berries are especially abundant. However, under cultivation the plant does not respond, as regards early bearing, as quickly as its near relative the Siberian sandthorn (*Hippophae rhamnoides*). It was found that the buffalo berries can be worked on the Russian form of oleaster (*Elæagnus angustifolia*). The fault of the buffalo berry is its small-sized fruit and the difficulty of gathering it, owing to its numerous thorns, but it has been and is an abundant source of pleasant fruit to thousands of settlers in the newer regions of the West. The fruit varies greatly in size and degree of acidity, affording opportunity for selection work in its native home along the Missouri River and tributaries. N. E. HANSEN.

**BUGBANE:** *Cimicifuga*.

**BULB, BULBS.** A bulb is a thickened, fleshy, and commonly subterranean bud, usually emitting roots from its under side. The office of the bulb is to carry the plant over an unpropitious season, as over winter or a dry period.

True bulbs are either tunicated, formed in rings or layers, like those of hyacinths and onions (Fig. 681), or scaly, like those of some liliaceae (Fig. 682); but as popularly understood and in commercial parlance, the term bulbs applies to a large class of flowering and ornamental bulbous-like plants in their dormant condition, during which period they are collected, dug, stored, shipped, sold and planted, like so many potatoes. This class includes, in addition to the true bulbs, many that are botanically known as corms, which are solid, as crocus and gladiolus (Fig. 683); tubers which are succulent and have the buds or eyes near the surface, as the dahlia and potato (Fig. 684); rhizomes, fleshy, creeping underground stems like certain iris, ginger, and many wild plants (Fig. 685); pips, the flowering crowns of lily-of-the-valley; and certain other dormant fasciculated fleshy roots like those of peonies, ranunculus, and the like. A variety of bulbs is shown in Fig. 686. The true or feeding roots grow generally from the base of the bulb, the stems, flowers and foliage from the crown

681. Onion bulbs.

of the bulb, or the eyes. There is an exception to this in certain lilies, which throw out roots above the bulb also (Fig. 687). The bulb is a storehouse for the plant, wherein is formed, after flowering, new stems, leaves and flowers. In fact, the bulb contains a new plant, which is protected and sustained within the bulb by the reserve food and energy collected therein

during one season for the plant's successor. After the flowering period, the plant above the bulb and the roots beneath it ripen off and die away. The bulb is then in a dormant condition. It is during this state of rest, lasting approximately from three to six months, that bulbs are taken out of the ground and transported easily and safely from continent to continent, if required; after which the incipient roots, stems, foliage and flowers may develop with as much luxuriance and perfection as if the bulb had remained in its original environment.

Bulbous flowering plants (bulbs) are very popular with flower-loving people. There is a particular charm and interest in growing them. As a rule, they produce flowers of remarkable beauty, unsurpassed by any other class of plants, and many of them are deliciously fragrant. They comprise an endless variety in habit, form, size and color, are adaptable for many purposes, and many of them flower equally well under either garden or house culture. Soon after their beauty fades they die away, or may be removed; and in the interval, their places may be occupied by other seasonable flowering plants. Not the least among the merits of bulbs is their ease of culture, and the great certainty and perfection with which their flowers are produced, under suitable conditions.

Among bulbous plants are many that are sufficiently hardy to withstand the severity of our northern winters. The kinds that are suitable are nearly all dormant in the fall, which is the proper time for planting them, and they will flower the coming season. In March or earlier, spring is ushered in with the blooming of snowdrops, chionodoxas, anemones, scillas, crocus, winter aconites, bulbocodiums and so on, followed in April with brilliant hyacinths, tulips, narcissus and hosts of others. In April appear the unapproachable late tulips, poet's daffodils, dicentras and the like, followed in succession until frost, notably with peonies, irises, hemerocallis, lilies, montbretias, tritomas and others.

Gardeners usually think of bulbs as divided into two classes,—hardy and tender, or those that stand freezing and those that do not. There is a class from South Africa known as Cape bulbs, which usually bloom in the fall. There are now so many improved hybrids and breeds that are crowding out the types, that the term "Cape bulb" has lost its significance in this country. In the present article, bulbs are treated under the following general heads: Hardy spring bulbs for design bedding; hardy bulbs in the herbaceous garden, mixed flower-border or lawn; subsequent treatment of outdoor bulbs; summer- and autumn-flowering tender bulbs for spring planting; bulbs for flowering in the house and greenhouse; the forcing of bulbs; other indoor methods; subsequent treatment of forced bulbs; keeping dormant bulbs, tubers, and the like; propagation of bulbous plants; hints on buying and selecting bulbs; catalogue of bulbs.

#### *Hardy spring-flowering bulbs for design bedding.*

The only bulbs adapted to geometrical beds are Dutch hyacinths and tulips. It is not best to use both in the same bed for really fine effects. For display bedding in parks, public squares, and like places, only solid bright contrasting colors as a rule are used, since brilliancy of coloring is advisable when the taste of large crowds must be considered. This limits the selection in hyacinths to dark crimson, rose-red, pink, purple, blue, lavender, white and yellow (the latter is seldom satisfactory), and in tulips to dark blood-red, scarlet, rose, blush-pink, yellow, white, and a bluish claret, which last is seldom used. On private grounds many beautiful effects can be obtained by the use of the softer colors, particularly in beds that are situated in partial shade. In ordering the bulbs for this style of bedding, it is important to select kinds that bloom at the same time and are of uniform height; and in the case of hyacinths to choose varieties with a strong stem,

for many sorts are liable to fall over from the weight of the spike and are quickly soiled when they lie on the ground. If the item of expense is to be taken into account, it is possible to use second-size bulbs of hyacinths, often listed as bedding sizes, with satisfactory results, although only fine bulbs give fine bloom.

In planting bulbs in "design beds," it pays for the extra trouble first to remove the soil to a depth of 6

682. Scaly bulb of *Lilium pardalinum*.

inches, spade up the lower soil, using well-rotted manure and plenty of bone dust worked in. Then level off, smooth, and cover with an inch of sand. This prevents the manure from touching the bulbs, and allows the water to drain away from immediate contact with them, thus removing causes which may lead to their decay. Bulbs set in this manner on the sand may be placed in their exact position, after which the top soil is carefully replaced. It is a difficult matter to set bulbs just 4 inches deep and 4 to 6 inches apart with an ordinary trowel. The planter is almost sure occasionally to chop off a piece of a neighboring bulb or displace it. Bulbs planted in the manner advised, being all of an even depth, will flower uniformly; often, when planted with a trowel, some bulbs will be an inch too high and some an inch too low, which in early spring makes considerable difference in the time of blooming. Besides, when bulbs are planted with a trowel or dibble, there is danger of "hanging" a bulb occasionally, where it may perish on account of not touching bottom.

*Hardy bulbs in the herbaceous garden, mixed flower-border, or lawn.*

The mixed border is a favorite place for most hardy bulbs. They should be planted in little colonies here and there among the hardy plants and shrubs; and it is here that bulbs seem to thrive and give the most pleasure. As spring approaches, the somber winter browns and dull greens of the deciduous and evergreen plants are suddenly transformed into an unrivaled setting, studded with brilliantly colored and fragrant flowers, the contrasts being exceedingly effective and cheery; and besides, from the border one does not hesitate to cut a few flowers for the house for fear of spoiling the effect, as would be the case in formal bedding. Furthermore, bulbs seem to do better and last longer in a border because the flowers are cut freely in bud or when just approaching their prime, which is the best possible time for the benefit of the bulb, for the efforts of any bulb to form seeds weakens the bulb. A hyacinth bulb that matures seed is virtually destroyed. Then again, in an herbaceous border the bulbs are not disturbed through the necessity for replacing them with other flowering plants, as such a mixed border when properly planted should do much itself to hide the withering leaves. The foliage then remains uninjured until ripe, thus fulfilling its duty of recharging the bulb with new energy for the next season's display. Of course, after three or four years, the bulbs should be divided if they have grown and spread, and judgment must be used to determine when the lifting should be done with the least injury to the other permanent subjects in the border. It is best, perhaps, to associate with the bulbs plants that are not seriously injured by being moved.

Bold clumps of the taller bulbous plants are very effective on the lawn, where beds of one kind should be isolated, and be given a position not too prominent nor too near. The object desired is a mass of one color, which at a little distance is more striking on account of the contrast with the surrounding green grass and trees.

Among the best hardy bulbous plants for this purpose are: *hemerocallis*, such lilies as *candidum*, *Henryi*, *tigrinum*, *speciosum* and *auratum*; also *dicentra*, crown imperials, *montbretias*, *tritomas*, peonies, and *Kaempferi* and *germanica* *irises*.

Bulbs planted right in the sod on the lawn make a very pleasing picture when in bloom in the early spring. Make patches here and there of golden, white and purple crocus, the little *chionodoxas*, snowdrops, *Scilla amara*, winter aconite, snowflakes, *bulbocodium* and *triteila*. These grow, increase, bloom and ripen the foliage mostly before it is necessary to use the lawnmower, so that the surface of the lawn in summer is not marred. The bulbs may be dibbled in when the ground is moist and soft during the fall rains, but it is better to cut and turn back the sod here and there, plant the bulbs under it, then press the sod back again.

For parks, groves and wild outlying grounds beyond the closely clipped lawn, a very happy style of "naturalizing" bulbous and other plants is coming much into vogue. Such bulbs should be used as can be planted in quantity, twenty-five to a hundred or more of a kind in a patch, and only those should be used which are hardy, and will flower and thrive and increase under neglect. Fortunately, there are many bulbous plants that succeed even better in such rough places than in the prim garden. Among them are hardy anemones, *camassia*, *convallaria*, *dicentras*, *erythroniums*, *funkias*, certain *iris*, *liliums*, poet's *narcissus*, *Von Sion* and many other *narcissi*, *trilliums*, and numerous others.

In regard to the preparation of beds for hardy bulbs, planting and treatment, one can only generalize. Detailed directions suited to the different species, and also varieties where treatment varies, will be found under their respective headings in this Cyclopaedia. As a rule, well-rotted manure (mind that it is well-rotted, not fresh and heating) should be liberally applied and dug into the ground deeply. It must be where the long, feeding roots can get at it, and yet not touch the bulbs, nor be too near their base. This is easily accomplished by removing a few inches of the top soil first, as described under "Design Bedding" above. If it is impracticable to do this, then it is not advisable to use manure at all, for the bulbs are liable to come in contact with it and become diseased. Bone meal alone is then the safest fertilizer to use, and it should be applied lavishly. Most bulbs like rich food if properly applied. Although the embryo flowers were formed within the bulb the season before, yet their size, luxuriance and brilliancy this season depend largely upon the nutrition the roots receive. Liberal applications of manure water, when the bulbs are in bud, often produce excellent results.

The proper depth to plant bulbs varies according to the kinds. It is a common fault to plant them too near the surface. Some kinds, notably the Californian *Humboldtii* and Washingtonian lilies, do best when 10 to 12 inches deep; hyacinths, tulips, *narcissi*, and similar large bulbs from 4 to 6 inches deep; smaller bulbs somewhat shallower. A good rule to follow is to make the depth three times the average diameter of the bulbs. Hardy bulbs root during the fall and early winter, and if planted too near the surface the freezing, thawing and heaving of the upper crust of soil in mild winters often causes the bulbs to break from their roots, and, in consequence, only inferior flowers are produced. When good cold

683. Corm or solid bulb of *gladiolus*.

weather has set in and a light crust has been frozen on the soil, then cover the bed with leaves, straw, marsh hay or reeds to a depth of about 4 to 6 inches. This protects not only from severe freezing, but from equally injurious unseasonable thaws. Do not put the covering on too early, for it might warm the soil so that the bulbs would begin to grow and afterward be injured from freezing. Gradually remove the covering in the spring.

The general run of bulbous plants thrive in a loamy soil, inclining to sand. This soil attracts moisture, allows free drainage, and admits air. If the soil is cold and stiff, a liberal admixture of leaf-mold and sand, with the addition of manure applied as previously described, will be beneficial. The texture of the soil should be such that stagnant water will not remain around the bulbs, as it tends to rot them, particularly when dormant. An excess of humus is, therefore, to be guarded against for most bulbs.

While most bulbous plants thrive under the soil conditions advised above, yet there are many exceptions. Happy should be the man on whose grounds is found a variety of soils and exposures, shade and sun. A small wooded valley or ravine, with a brook flowing through it into an open, moist meadow, affords conditions suitable for growing to perfection the greatest variety of bulbous and other plants, many of which cannot be enjoyed in the average garden. The hyacinth is a notable exception in regard to soil conditions. In Holland this bulb is grown in pure sand, and soon becomes diseased in heavier soil. This should indicate that in this country plenty of sand should be added to the natural soil, and that the bulbs should not be left in the ground during the summer.

The sooner bulbs can be put in the ground after they are ripe, the better for the bulbs; for, no matter how long they will keep, they do not improve when out of the ground, but tend to dry out and lose vitality. This is particularly true of the narcissi, which give very noticeably larger flowers when the bulbs are planted early. All of the sorts having a strain of poeticus blood begin the new root-growth almost as soon as they have ripened, and are far better off if they can be in the ground early. There are, however, many reasons why bulbs cannot be planted as soon as ripe; and when they are to be kept for certain purposes, they should be stored as advised below. Hardy spring-flowering bulbs should be planted in the open ground in the fall, not earlier than six weeks before regular frosty and freezing nights are expected. Plant as much later as necessary, providing the bulbs are keeping sound, but it is not advisable to plant them earlier. Cool weather is necessary to deter top growth, which is very liable to start after four

to six weeks of root development; and young, succulent top growth is apt to be injured by the succeeding freezing. In Maine, Ontario, Wisconsin, and other northern parts (about 45 degrees north latitude), such hardy bulbs as hyacinths, tulips and narcissi, may be planted in September. In New Jersey, Pennsylvania, Ohio, and so on (about 40°), plant about the middle of October.

684. Potato.—Example of a tuber.

In the latitude of Richmond, Louisville, and St. Louis, the middle of November is early enough. In the latitude of Raleigh, Nashville, and south, do not plant until middle of December; and for the latter section let the selection of bulbs run to late-flowering varieties, such as Bizarre, Darwin, and late double tulips, late hyacinths, late narcissi, and the like, for they are not so likely to be caught by the occasional freezing weather in January and February. In this southern latitude, however, very early-flowering bulbs, such as Roman hyacinths, Duc

Van Tholl tulips, Early Polyanthus narcissi, and so on if planted in September, are usually through blooming before freezing weather begins. South of the freezing belt, hardy spring-flowering bulbs are not very successful, as a rule, there being no sufficiently cool weather to deter top-growth and force root-action first, without which the flowers and foliage will not develop beyond such sustenance as the bulb can supply; and this sustenance is usually exhausted by the time the flower-spikes are half grown. But there are many half-hardy and tender bulbs that are more easily grown and flowered in the South than in the North.

#### *Subsequent treatment of outdoor bulbs.*

The treatment of bulbs after flowering is important when the bulbs are to be used again, for it must never be forgotten that the flowers and resources for the next season are garnered within the bulb after blooming, through the agency of the roots and foliage. Imperfectly developed and matured foliage this year means poor flowers or none at all next year; so it is best to leave the bulbs alone until the leaves have died down. The further treatment depends upon the kind of bulbs under consideration. Generally speaking, one class may be left in the ground for a number of years, while another thrives better if lifted annually and given a short period of rest out of the ground. Among this latter class must, of course, be included tender bulbs which will not survive the winter if left in the beds or borders and which should be taken up in the fall when matured. Of the hardy bulbs, hyacinths and tulips succeed best if lifted annually. Late tulips in borders may be left undisturbed for two or three years with fairly good results, but the single early kinds ought to be taken up each year.

Lifting of any bulbs should never be done before the foliage assumes a decidedly limp and brown appearance. From that time on until the root-growth begins, they may be taken up, cleaned, and stored away, or divided and replanted at once. The former method is advisable for hyacinths and tulips; the latter for most of the bulbs on the list appended hereto. When bulbs are grown commercially, this yearly lifting is essential in order to make provision for propagation by division or by offsets, as the young bulbs mature more rapidly and perfectly when separated from the parent bulb. When summer bedding-plants are to be substituted, it is sometimes necessary to remove bulbs before ripe. In such cases, the bulbs should be carefully taken up with a spade. Disturb the roots as little as possible, and do not cut or crush the leaves. Heel-in the plants in a shallow trench in some half-shady out-of-the-way place until ripe, taking pains to avoid setting them too close in the trench to secure some air-space about the tops. If the soil adheres to the roots when taken from the beds, the bulbs will be less affected by being disturbed before maturing. As soon as ripe, they should be dug up, cleaned, and stored away. A point to be kept in mind is that it is safer to lift tulips too early than too late; these bulbs should be taken up just before the stems are quite dry. By doing so the protective skin about the bulb is more likely to be retained during the time the bulbs are out of the ground. Darwin tulips have especially thin skins which frequently loosen and come off entirely if the bulbs are left too long, and then the bulbs tend to become soft and flabby during the resting period. Narcissi should be taken up with whatever foliage has not quite withered away. Indeed, it is always wisest never to cut a leaf from choice kinds, but to make plantings of cheap kinds if leaves are wanted for cutting.

#### *Summer- and autumn-flowering tender bulbs for spring planting.*

This class (tender) includes some of our showiest garden flowers, which are almost indispensable. They are of the easiest possible culture. Planted in the spring,

after danger from frost is over, in a sunny position in good rich soil, they will flower with great certainty the same season. After flowering and ripening of the foliage, they should be taken up and stored for the winter as advised under "Keeping dormant bulbs" (p. 593) until wanted next spring. Among the more important species of this class of bulbs are the undermentioned (those marked F must be kept in a semi-dormant condition in a coldframe or greenhouse): *Agapanthus* (F), *Alstremeria* (F), *amorphophallus*, *anomatheca* (F), *antholyza* (F), tuberous *begonia*, *bessera*, *colocasia* (*caladium*), *cooperia*, *crinum*, *cypella*, *gladiolus*, *galtonia* (*Hyacinthus candicans*), *houssingaultia* (*madeira* vine), *montbretia*, *nemastylis*, *border oxalis*, *ornithogalum* (F), *pancratium*, *richardia* (*calla*), *schizostylis* (F), *sprekelia*, *tigridia*, *tuberosa*, *watsonia*, *zephyranthes*.

#### *Bulbs for flowering in the house and greenhouse.*

There is no class of plants that gives more satisfaction for this purpose, with so little skill, than the various bulbs. Perhaps the most important class of all bulbs for winter-flowering and forcing are certain hardy and half-hardy kinds. They are the most easily managed of all, and need occupy no space in the window or greenhouse, excepting when in bud and bloom. Under suitable treatment, they flower with great certainty, and their flowering period may be hastened (forced) or retarded at pleasure, so as to "bring them in" for certain occasions, or to give a continuous succession of bloom. There is a great variety of kinds of bulbs to select from for this purpose (see list of species at end of this article), yet the great demand, at this writing, has centered on the following leaders, especially for forcing purposes: *Allium neapolitanum*, *A. Hermetii grandiflorum*, *Anemone fulgens*, *convallaria* (*lily-of-the-valley*), *Freesia refracta alba*, *gladiolus* "The Bride," early single-flowering Dutch hyacinths and Romans, *Campanelle jonquil*, *Lilium candidum*, *L. Harrisii* and *L. longiflorum*. Several narcissi are in demand, notably among the large trumpet varieties: Emperor, Empress, Golden Spur, Horsfieldii, and Spurius major; among the medium and small trumpets: Sir Watkin, Barrii conspicuus and Poeticus ornatus; of the doubles are Von Sion and Orange Phoenix; of the Polyanthus narcissi: Paper White grandiflora (*Totus albus*), and double Roman (*Constantinople*). Of other species of bulbs, *Ornithogalum arabicum*, *spirea Gladstone*, and single and double tulips of the early varieties are in demand. In the classes of bulbs there is often a great diversity in the fitness of the varieties for forcing. Certain sorts will be found best adapted to early forcing, others to midseason or late work, and in selecting bulbs for forcing these characteristics must be taken into consideration. Besides this general division into early and late forcing kinds, the skilled grower recognizes that each variety has its own peculiar period when it is at its best, if forced. Many tulips and narcissi are very fine if forced early and only moderately good if forced late; the converse is equally true, for often an early variety will do only indifferently well when it is used for late work. This characteristic is well studied by one of the largest forcers for the English market, who devotes whole separate houses to particular varieties of tulips, and puts in charge of each one man who knows the whims of the variety he tends. This should not, however, deter anyone from attempting to force bulbs, as success is sure to be gained if standard forcing kinds are used, and the few important rules are followed. The principles of culture for hardy bulbs for winter-flowering are the same, whether only a few are grown in pots for the window-garden, or whether they are to be forced by the thousand by the florist. The first essential is to secure the strongest bulbs. Remember that the flowers were formed within the bulbs the previous season. If one buys bulbs of narcissi containing only one flower, or hyacinths with only ten bells on a spike, the best

culture possible cannot make them produce more; but good culture will develop such flowers larger and better.

The next most important essential—one might say the secret of success in flowering bulbs in house or greenhouse—is perfect root-development before the tops begin to grow. To aid the uninitiated in this important matter, we will illustrate: When hardy bulbs are planted in the open ground in the northern states in the fall, the weather above them is cool or cold, the ground beneath

685. Example of a rhizome—*Smilacina racemosa*. The figures show the different years' growths.

them is warmer, and the conditions are congenial for root-action but deterrent to top-growth. This results in the perfect development of such flowers as the bulbs contain. On the other hand, when hyacinths, tulips, narcissi, and most other hardy spring-flowering bulbs are planted in fall in our extreme southern states, they may prove disappointing, because the weather is warm, causing the flowers and foliage to begin to grow before the roots; and as soon as such sustenance as the bulb could supply has been exhausted, the plant stops growing and dwindles. When one grows bulbs under artificial conditions, one must make them produce roots first. Failure to do this is responsible for nine-tenths of the disappointments.

When hardy bulbs are to be grown in pots for winter blooming in the house or conservatory, the bulbs should be potted as soon as they are procurable, between August and November. Some writers recommend that bulbs be planted in successional lots to give later and continuous flowers, but such advice is at fault, as the bulbs tend to dry out and lose vitality when kept dry too long. It is no trouble to retard the flowering of hardy bulbs in winter, as hereafter described, without keeping them out of the ground.

The soil should be rich loam. Fresh manure cannot be used. Of thoroughly rotted manure, some may be pulverized and worked into the soil, but it is safer to use pure bone meal, one part to fifty of soil. If the soil is stiff and heavy, mix with it sand and leaf-mold or peat. The size of pots depends upon the kinds of bulbs. A 5-inch pot is best for a first-sized hyacinth, or large-bulbing narcissus, particularly the polyanthus type. Tulips, small narcissi, and bulbs of a similar size, while they can go individually into a 4-inch pot, are better when put three or more of one variety together in a larger pot, as the soil retains a more even temperature and moisture; and for this reason some prefer earthen bulb-pans, which come in various sizes, from 8 to 18 inches in diameter. In potting, place a little broken pottery or lumps of charcoal in the bottom for drainage, then fill the pot with soil and shake it down, but do not pack it. Neither must the bulb be pressed or screwed into the soil, else the soil will be packed under it so that when the roots start they often raise the bulb out of the pot. Plant the bulb just deep enough that its top will not show. Large and soft bulbs, which are liable to rot, may be set in a cushion of sand, and the bulb not covered with soil until it has taken root and become established (Fig. 688).

When planting mixed bulbs in the same pot, pan or box, care should be used in selecting different varieties that will flower at the same time. An early-flowering Duc Van Tholl and a double Tournesol tulip would flower a month apart under the same treatment. Some varieties of hyacinths, of narcissi, and of most species of bulbs vary greatly in time of blooming, which, of course, would spoil the effect.

#### *The forcing of bulbs.*

When florists force bulbs in quantity for cut-flowers, they seldom use pots, but shallow boxes, or flats, of a size to economize bench-room. Usually these boxes are cut down from soap-boxes to a depth of 3 or 4 inches. The bulbs are planted closely in these, from an inch to 2 inches apart, according to the kind. The tops of the bulbs (excepting lilies) are kept about even with the top of the soil. Give a thorough watering to help settle the earth about the bulbs, but give no more water until growth begins, for bulbs in a dormant condition resent an excess of moisture. After the bulbs are potted, or boxed, as described, they should be placed in a cold-frame or cold-pit to root. This is the most important detail in flowering bulbs under artificial conditions.

686. Various types of bulbs and tubers.

1. Tuberose. 2. *Colocasia antiquorum* (*Caladium esculentum*).
3. Easter Lily. 4. Jonquil. 5. *Gladiolus*. 6. *Lilium pardalinum*.
7. Hyacinth. 8. Lily-of-the-Valley.

Cover the pots, boxes or pans with 4 inches of sand, ashes, rotted leaves, tanbark or similar substance, and do not put the sash on until freezing weather, and even then remove the sash on pleasant days. When no coldframe or pits are available, the pots may be covered as advised in a cool cellar, provided close attention is given to be sure that the soil is maintained in a uniformly moist, but not wet condition. It is preferable however, to sink them in the open ground. Very fine flowers were obtained from hardy bulbs when treated as follows: A trench a foot deep is dug in the garden where water will not settle in it, and it is protected from the north and west cold. Three inches of coal-ashes is first placed in the trench, to allow drainage and keep the worms out. The pots are then placed on the ashes, the earth is filled in about the pots, filling the trench rounding over. When the weather gets cold enough to freeze a crust on the soil, an additional covering of about 4 inches of rough stable manure, leaves or straw, is put over. This cover must be heavy enough to keep the pots from freezing, not that this will injure the bulbs, but that it will be almost impossible to remove the pots if the covering of earth freezes solid. Care should be taken that the sides of the trench do not fall in, depositing a layer of earth over the leaves or other cover, which will freeze hard enough to make removal difficult. Often a simple cover of 8 to 10 inches of leaves directly over the pots will be most advantageous if earth has been worked in about the sides of the pots to retain moisture. No further attention is required, as every-

thing is congenial to perfect root-development, while the weather is cool enough to check top-growth. Some early bulbs, such as Roman hyacinths, Paper White narcissi, Duc Van Tholl tulips, and the like, will root sufficiently in five or six weeks to be taken up for first flowers, which should be out by Christmas or earlier, but it is safer to allow all bulbs not less than eight weeks for rooting. A fairly sure indication that the bulbs are ready to be brought into heat is the appearance of about an inch of top growth, and of an abundance of roots through the bottom of the boxes or through the holes in the bottom of the pots. Every two weeks after the first removal of pots, or as needed, further relays of rooted bulbs may be taken out for a continuous display of bloom. When the pots of hardy bulbs have been taken up, place them in a cool greenhouse or cool, light storeroom, with temperature not over 56°. This temperature will allow the flower-stems and foliage to grow, and at the same time prevent the opening of the flowers until the stems have attained their proper height. The pots should be kept shaded for several days until the top-growth has taken on its natural green color, after which the pots may be taken to a sunny, warm window, or wherever they are wanted to flower. Bulbs treated in this manner will produce perfect spikes of flowers.

A practice often followed by florists early in the season is keeping the bulbs in the dark and in heat in order to draw out the flower stems to a proper height. This can often be accomplished by placing an inverted pot over the tops, the light coming through the hole in the bottom being sufficient to draw out the stems. If this is done, the bulbs must be watched to see that the tops are all growing evenly; should some of the bulbs get a start of the others, the pots must be put in the light at once to avoid irregularity in flowering. For early work, this darkening, together with strong bottom heat, will give longer foliage and stem than if the bulbs are subjected to strong light when first brought under glass. But plenty of fresh air must be afforded, and as the buds begin to show color the pots must be removed to a cooler temperature to harden the growth, and enough light given to put color in the foliage and the buds.

A good rule to keep in mind in flowering hardy bulbs is: Temperature, 40° for roots, 50° for foliage and stems, 60° for best flowers, 70° for quick development, 80° to rush bloom with loss of substance and risk of "going blind" (producing no flowers).

The exceptions to the above advice are liliums and lily-of-the-valley. The bulbs of *Lilium Harrisii*, *L. longiflorum* and the various sorts of *L. speciosum*, in addition to throwing out roots from the base of the bulbs, usually form roots from the new stem just above the bulb, and the plants and flowers derive much strength from these top-roots. So in potting lily bulbs, it is best to put them down so deep that there will be sufficient soil above the bulbs to entice and sustain the stem-roots. This may be done when the bulbs are potted, or 2 or 3 inches of soil may be added after growth is under way and the stem-roots have begun to work into the soil. An advantage in the latter method is that some fertilizer may be mixed with the new soil, and sustenance provided when it is most timely. In other respects treat the bulbs after potting as just advised. Winter-flowering lily-of-the-valley forms no new roots. The thick, fleshy, fibrous old roots should be trimmed at the bottom, leaving them from 2 to 3 inches long. This allows them to absorb the abundant moisture with which they should be supplied while the flowers and foliage are developing. They flower just as well in sand or moss, or anything that retains an even moisture and temperature, as they do in soil, but lily-of-the-valley for flowering in the house or greenhouse requires freezing before it can be successfully brought into flower. Without freezing, many pips will "come blind," or pro-

duce malformed spikes. So it is just as well for amateurs to plant their pips an inch or two apart in pots or bulb-pans, and plunge them in the garden, as recommended for other hardy bulbs. Florists generally freeze their pips in refrigerators, or have them placed, just as they arrive from Germany, 2,500 pips in a case, in cold storage, in a temperature of 28° to 30°.

Half-hardy bulbs for winter-flowering and forcing should be treated the same as hardy bulbs, except that after potting they should be placed for rooting where they will not freeze. Yet they can go fairly close to it and be all the better for it. In northern states, a coldframe or pit or cold greenhouse to root them in is, therefore, almost indispensable. For tender winter- and summer-flowering greenhouse bulbs, the culture varies with almost every species, and as no general instructions would suit all kinds, the reader may refer to their individual cultures given under their respective headings in this Cyclopaedia. (See list of species at the end of this article.)

#### *Other indoor methods.*

The flowering of bulbs in glasses, bowls or unique pots, is always interesting. Among the most successful and interesting are hyacinth bulbs in glasses of water. Use early-flowering single varieties only. The seedsmen and dealers in bulbs supply special hyacinth glasses for the purpose. They come in various shapes, colors and decorations, and vary in price from 20 cents to \$1.50 each. These are simply filled with fresh, pure water. A lump of charcoal thrown in absorbs impurities, but it is not absolutely necessary. The bulb rests in a cup-shaped receptacle on top of the glass. In filling, the water should not quite touch the bottom of the bulb. Put in a cool, dark, airy place until the roots have reached the bottom of the glass, which should be in about six weeks. Do not place them in a close, warm closet. They must have fresh air. As the water evaporates, fill the glasses, and change the water entirely when needed to keep it sweet and clear. After rooting, place the glasses in a light store-room where the temperature averages about 50°, until the stems and foliage have developed; then remove to a warm, sunny window for flowers to open. There are other kinds that do equally well when rooted in water, providing the largest healthy bulbs are chosen. Among them are sprekelia (Jacobæan lily), Trumpet narcissi *Horsfieldii* and Golden Spur, polyanthus narcissi *Grand Monarque* and *Gloriosa*, large bulbs of Roman hyacinths, early single tulips, and Mammoth Yellow crocus. Hyacinths have been flowered on a piece of virgin cork floating in an aquarium, a hole being cut through the cork for the roots to reach the water. The so-called "Chinese sacred lily," a variety of *Polyanthus narcissus*, grows and flowers luxuriantly in bowls of water, provided they are not placed in a dry, furnace-heated room, which will cause the buds to blast before opening. Sufficient pebbles or shells should surround the bulbs to prevent them from toppling over.

Crocuses, Roman hyacinths, and lilies-of-the-valley are very pretty when nicely flowered in columnar, hedge-hog- or beehive-shaped hollow pots with holes for the reception of the bulbs. A bulb is placed in front of each hole from the inside, with the crown of the bulb looking outward. The pot is then filled with soil through the large opening in the bottom, moss being pressed in last to hold the contents in place, after which the pots

are put outside for the bulbs to root, as explained for other hardy bulbs for the house.

The growing of bulbs in moss fiber, a method introduced by Robert Sydenham, of Birmingham, England, is well deserving of attention by the amateur. The great advantage of this method is that the bulbs can be grown in decorative china bowls, without drainage, while the compost is clean to handle and, as the bowls are not porous, they may be set about a room without danger of spotting the most highly polished woodwork. The compost is made up of moss or peat fiber and ground oyster-shell in the proportion of three parts dry moss to two parts of the shell; a little pulverized charcoal added tends to keep the material sweet. The moss must be rubbed between the hands thoroughly to break even small lumps and then mix the shell with it very carefully, after which water should be slowly added in the proportion of four quarts to each half-bushel of the mixture. When properly moistened the compost should feel quite damp but no water will be squeezed out if a small quantity is pressed tightly in the hand. A few pieces of charcoal should be placed in the bottom of the bowl to keep the fiber sweet, and the bowls should be filled to within about an inch from the rim. Cover the bulbs with an inch or so of the mixture, taking care not to pack the fiber in so doing, and place the bowls in a cellar or cool room where they can have plenty of fresh air.

For about three weeks the mixture will itself provide sufficient moisture, but after that time they must be examined frequently; nothing is so essential as keeping the fiber uniformly damp to the very bottom of the bowls but there must be no water standing. If dry for but a day there is great risk of the bulbs going blind. The treatment from this point on is identical with that given for bulbs grown in ordinary potting soil.

#### *Subsequent treatment of forced bulbs.*

After being forced or flowered in the greenhouse or window, hardy bulbs are of little value, for most bulbs suitable for the purpose have attained their maximum size, and, in consequence, are ready to break up. Florists usually throw these bulbs away. However, if space can

be spared for the bulbs to complete their growth after flowering, and watering and temperatures are watched, many of them can be matured to be utilized afterwards. The ripening of the foliage is as necessary to forced bulbs as it is to those grown in the open, and to promote this the potted bulbs should receive enough care and nourishment to counteract the artificial conditions under which they are grown. When it is desired to keep forced bulbs, the compost should be made somewhat richer at potting time. After flowering, the pots may be plunged out-of-doors, if freezing weather is over, until the foliage has ripened. Then the bulbs can be shaken out and planted in the mixed border or about the kitchen-garden, where some of them will recuperate and give flowers for cutting within a year or two, and eventually they will regain their vigor sufficiently to be transferred to the bulb-garden. Yet with most of the bulbs the labor involved is scarcely commensurate with the returns, and the bulbs might just as well be discarded at the beginning.

#### *Keeping dormant bulbs, tubers, and the like.*

Bulbs and tubers of the various species, as well as their varieties, vary greatly in size. Some, like oxalis, snowdrops, and chionodoxas, often do not exceed half

687. The Easter lily throws out feeding-roots both below and above the bulb.

an inch in diameter, while other bulbs, such as those of *Caladium esculentum*, certain arums and crinums, attain great size, frequently weighing several pounds each. Such solid bulbs as those of tulips, hyacinths and narcissi, will remain out of the ground solid and plump, in a suitable place, for three or four months. The larger the bulb the longer it will keep, as a rule. Large crinum bulbs have been kept for fifteen months. Still, it is always better to plant the bulbs as soon as possible, for, although they keep, they do not improve, and their tendency is always toward drying out and loss of vitality.

Never keep bulbs packed air-tight. They are liable to generate heat or sweat, mold or rot, or to start. When solid bulbs are to be kept dormant for any length of time, they should be stored away from bright light in baskets, shallow boxes or slatted trays, protected from rats or mice, in a room or cellar in which there is a circulation of fresh air and the temperature is as cool as possible. Forty degrees is the desideratum for all excepting tender bulbs. Scale-like bulbs, as liliums, soon dry out and shrivel, if exposed to the air for any length of time; therefore, they are best kept in open boxes packed with some substance that will retain a slight and even moisture, such as sphagnum moss, rotted leaf-mold, coconut fiber refuse, or moist sand, but they must be kept cold to check any efforts to start. Fleshy roots, like those of peonies, and so on, should be treated like the lily bulbs. When a cold-storage room, with an average temperature of 36° to 40°, is available, it is the safest place to carry over hardy bulbs and roots for spring planting.

Lily-of-the-valley pips are carried in cold storage rooms of about 28° to 30°. The pips and packing freeze solid; and here they are kept for months until wanted for forcing. When they are removed, they must be thawed out gradually and as soon as possible, by plunging in cold water, before they are subjected to any heat; otherwise, they are likely to rot. For this reason, "cold-storage pips" cannot be safely shipped any

683. Bulb with a cushion of sand beneath it to prevent decay.

distance in warm weather, this often being the cause of the country florists' disappointment in results.

Tender dormant bulbs, as begonias, gloxinias, amaryllis, panceratiums, tigridias, tuberoses, must be kept in a warm, dry atmosphere, not below 50°. The cause of tuberoses not flowering is often that the bulbs have been kept below 40°, which destroys the flower germ,

although the foliage grows just as vigorously. Tender tubers, such as dahlias and cannas, should be stored in dry sand in a warm, dry cellar or under the greenhouse bench.

#### *Propagation of bulbous plants.*

Bulbous plants increase usually in either of two natural ways—from division or from seed. Increase by division, with true bulbs and corms, is due, in the first place, to the tendency these plants have after reaching a certain age to break up into a number of smaller parts, each part making a new start for itself and developing with time into a bulb of flowering size. In addition to this breaking up, all bulbs, even those of young growth, form tiny bulbels or offsets, throughout their time of maturing. These bulbels appear in many ways, some forming outside of the protecting skin of the mother bulb, as in the case of the tulip and hyacinth, others developing about the base of a newly-formed corm like the gladiolus. In this connection it is proper to note that the formation of bulbs during the growing season varies

in that some kinds form an entirely new bulb, as the tulip and gladiolus, and others merely add new tissues to the old bulb and increase in size, as the narcissus and hyacinth. As a rule, small bulbs obtained by this process of breaking up do not have the vigor of those from offsets; the younger a bulb is, the greater vigor it always has, although the flower may not show its true size.

Whereas bulbs secured by division always come true, —that is, the flowers resemble that of the parent bulb, allowing for the occasional variation due to "sporting"—propagation by seed is likely to give new varieties, differing in character from the original. Certain kinds of bulbs, such as the scilla, chionodoxa, or freesia, can be propagated by seed and come true, unless cross-fertilized. Bulbs grown from seed take longer to mature than do those from offsets, and for commercial purposes the seed method is seldom employed except when the raising of novelties is an object.

Of the other so-called bulbous plants which are under consideration here, the tuberous kinds increase naturally by the development of new eyes which grow into young plants as the old tuber decays, while the rhizomatous sorts form new plants through the elongation and branching of the running underground stems accompanied by the dying back of the older parts. Artificial propagation of these kinds is an easier affair than with true bulbs, as the separation of the new growth is readily effected by division with a knife, or even with the rougher use of a spade. Such tubers as potatoes, begonias and gloxinias can be cut into small parts wherever an eye has started, and these planted out separately grow into new plants. With certain kinds it is a frequent practice to dust over the tubers where the cut has been made with sulfur or soot to prevent decay. Caution must be used in following this method, as too frequent division of this sort results in weakening the vigor of the stock to be grown. Several tubers, such as the dahlia and begonia, can be propagated either by stem or leaf cuttings taken from the young growth.

Artificial propagation of the hyacinth by cutting the old bulb is the method employed in Holland, while many liliums are increased by loosening the outer bulb scales and inserting them in sand after the manner of cuttings. Certain bulbs like the tulip, as grown in Holland, are subjected to heat after lifting, to ripen the bulbs more thoroughly. Bulbs to be used for propagating are given a higher temperature, which arrests the flowering and tends to increase the breaking up of the mother bulbs. For special methods of propagating, the reader should consult the articles on the various bulbs throughout this Cyclopaedia.

The cultural treatment for the young bulbs is in general the same as that prescribed for the older, larger ones. The offsets need not, of course, be planted so far apart, the very smallest being simply scattered in drills as peas or beans are sown. At first the soil should be somewhat lighter than later on, and must always be kept free from weeds and well cultivated. The young bulbs should be planted early, and when annual lifting is practised they should be the first to come out of the ground.

From an economic point of view it is doubtful whether the so-called Dutch bulbs can be successfully propagated and grown in America. The extremely low cost of labor, and the rapid increase of stocks in the soil and climate of Holland, together with the fact that the secret of ripening the bulbs to perfection is known thoroughly only by the Dutch, makes it improbable that bulbs can be grown as well, or with a reasonable profit, here in America.

#### *Hints on buying and selecting bulbs.*

As already said, bulbs can develop only the flowers which were formed within them before they were ripened. A bulb may be poor because not full-grown or too young, or because grown in impoverished soil or under

XX. A border of hardy bulbs.

uncongenial conditions, or because it may not have been matured when dug; or it may be injured from heating, sweating, rotting or moldiness in storage or transit, caused by improper curing or packing, or it may be dried out from having been out of the ground too long. In the majority of cases in which poor bulbs are planted, however, it is the buyer's fault in procuring cheap bulbs, which in many cases are second grades, lacking age and proper size. The commoner varieties of a species usually propagate the fastest, and it is generally these less salable varieties and inferior seedlings and cullings from the named bulbs that go to make up most "mixed colors" and "mixed varieties." Therefore, for best results, it is advisable to expend a given amount of money for the first-size named varieties, rather than for a larger quantity of cheaper seconds and mixtures, unless, of course, the bulbs are wanted for large permanent plantings, as in promiscuous borders for naturalizing, in which best flowers the first season are of secondary consideration.

The best named hyacinths—"top roots," as they are called in Holland—require from four to six years to attain full size and give best flowers. Such bulbs, according to the variety, should measure from 20 to 24 centimeters (8 to 10 inches) in circumference. These naturally cost more to grow than the younger second or "bedding" grade of bulbs, measuring from 18 to 20 centimeters (6 to 8 inches). There is a third size, ranging from 16 to 18 centimeters (4 to 6 inches), that goes in mixtures, and a fourth size (12 to 14 centimeters) that goes out as "Dutch Romans," "Pan Hyacinths," "Miniatures," and so on. Some growers even scale their sizes a centimeter or two less than mentioned, to enable them to quote lower prices. Crocus, narcissi, tulips and many other bulbs are also sorted into sizes, enabling the growers to catch all classes of buyers.

A first-size crocus bulb should measure 10 centimeters (4 inches) in circumference, and such bulbs produce from six to twelve flowers each. A small, cheap bulb produces only two or three flowers. A narcissus bulb of maximum size will produce from three to five flowers (sometimes more), and an inferior size usually but a single flower. A white Roman hyacinth bulb 14- to 16-centimeter size (5 to 6 inches in circumference) will produce three and often four spikes of firsts and several seconds, while an 11- to 12-centimeter size will average only one first-grade spike and a couple of seconds, or perhaps nothing but seconds. The best lily-of-the-valley pips bear from twelve to sixteen bells on a spike, usually all firsts. Cheaper inferior grades of pips have seldom more than seven to ten bells. If the florist or planter wants the best bulbs, he must pay more money for them, but they are cheapest in the end, for second-grade stock takes up just as much room and requires as much care, fire, and other expenses. It is the grade of flowers called firsts that sell and pay a profit. The supply of seconds is often so abundant that the market price for them does not pay the cost of the bulbs.

Mere size alone should never be taken as the standard in judging bulbs, however, as in this respect there is always a great difference among varieties of the same kind of bulb. A plump, solid bulb, without any suspicion of flabbiness, will give far better blooms than one without these qualities, but if size goes with them the purchaser will be just so much better satisfied. Furthermore, the selection of varieties is of importance since in recent years a great many vastly improved varieties in all classes of bulbs have been introduced. The growers, nevertheless, because of the demand for the older sorts, of which they have large stocks, continue to list many kinds no longer worth growing, unless cheap bulbs are wanted. Attention ought also to be paid to the fact that a number of varieties appear in the lists under different names, a feature of the bulb trade which often leads to great confusion although the rela-

ble dealers usually note synonymous names in such cases. Cheap bulbs may often be secured through the auction sales in fairly good quality, but it is utterly impossible to count upon these being true to name, or even to color. The surest way to obtain first-class bulbs

689. A good pot of narcissi.

is always to purchase from a trustworthy source, and to state clearly, when buying, the exact purposes for which the bulbs are intended and the amount which the buyer desires to spend.

#### Catalogue of bulbs.

To aid in the selection of bulbs for particular purposes, is appended a list of the leading species that are procurable while dormant (between the months specified) from seedsmen and bulb dealers, and a sign is affixed to each to indicate the purpose for which the species—or certain varieties in it—are adapted. Some kinds are useful for more than one purpose, and such have a corresponding number of signs. For example: If a selection of bulbs is to be made for winter-flowering in the house, make a note of those to which an asterisk (\*) is affixed, then turn to their respective headings in this Cyclopedia, where will be found other advice and descriptions; read all cultural instructions carefully, and consult good growers and reliable dealers for the most recent varieties in any species, remembering that new varieties frequently appear.

For winter-flowering bulbs for greenhouse or window, select from species marked \*.

For summer- and fall-flowering bulbs for pots for greenhouse and other decoration, select from species marked †.

For spring-flowering hardy bulbs for gardens, lawns, and the like, select from species marked ‡.

For summer- and fall-flowering hardy bulbs for gardens, lawns, and the like, select from species marked §.

For summer- and fall-flowering (not hardy) bulbs for spring planting in garden, and the like, select from species marked ¶.

For climbing bulbous plants, select from species marked ¶.

Those marked H are hardy; HH, half-hardy; T, tender.

Zephyranthes * ?	HH.	Aug. to Apr.

PETER HENDERSON & CO.

**BULBINE** (Greek, *bolbos*, a bulb). *Liliacæ*. More than 20 species of half-hardy African and Australian plants, allied to *Anthericum*, but practically not cultivated in this country.

Flowers showy, the petals distinct, 1-nerved, spreading and often recurving in age; stamens shorter than the perianth. Some of the species are bulbous, and require the general treatment given Cape bulbs (see *Bulbs*); but none of the bulbous species is known here.

690. *Bulbine annua*.

*annua*, Willd. Fig. 690. Annual, acaulescent, without any rootstock or bulb: lvs. 12–20, erect but weak: fls. bright yellow, racemose. S. Afr. B.M. 1451 (as *Anthericum*). D.C. Pl. Grasses, pl. 8.—Can be grown as an annual S.

N. TAYLOR.

**BULBINÉLLA:** *Chrysobactron*.

**BULBOCÔDIUM** (Greek, *woolly bulb*). *Liliacæ*. Crocus-like bulbous plants of mts. of Eu. and Russian Asia, spring-flowering or autumn-flowering.

Leaves appearing after (or before) the fls., usually 3, narrow, sheathed at base: fls. close to the ground, 2–3 from each bulb, the perianth funnellform, segms. distinct to the base but conniving in a tube; stamens 6; style 3-fld. at the top.—One variable species, treated in general as crocuses are cult. Allied to *Merendera*, to which some of the former species are referred.

*vénum*, Linn. Fig. 691. Blooms in gardens in earliest spring before the lvs. appear, the fls. resting nearly on the ground: fls. rosy purple, white-spotted on the interior, 1–3 from each bulb: lvs. broad and channelled. B.M. 153 (cf. Fig. 691). F.S. 11:1149. Gn. 75, p. 409.—Bulbs should be taken up and divided every 2 or 3 years. Plant in the fall. Usually blooms in advance of the crocus. *B. versicolor*, Spreng. (*B. ruthenicum*, Bunge), is a small handsome form.

L. H. B.

**BULBOPHYLLUM** (Greek, *bulb*-leaf). *Orchidacæ*. Epiphytic plants, creeping upon rocks or trees; cult. in the warmhouse.

Pseudobulbs 1–2-lvd in the axils of the sheaths, and with the infl. arising from the base of the pseudobulb: fls. small and numerous in a raceme, or larger and few

or solitary; dorsal sepal erect or spreading, free, equaling or shorter than the lateral, which are obliquely broadened at the base and adnate to the foot of the column; petals shorter than or nearly equaling the sepals; lip articulated to the foot of the column, incumbent upon the column; pollinia 4.—A genus of about 125 species, mostly natives of Trop. Asia and Afr.—Bulbophyllum needs a moist atmosphere and should not become dry. Grown on pieces of wood or tree-fern stems.

691. *Bulbocodium vernum*.

- A. *Fls. large, solitary.*  
B. *Petals and lip minute; sepals tessellated with pale brown and yellow.*

*grandiflorum*, Blume. Pseudobulbs 2–3 in. long, 1-lvd.; lf. up to 10 in. long and 2 in. broad, emarginate at the apex; peduncle usually not exceeding the lf. with 2–4 bracts and a solitary large fl. about 8 in. long;

sepals tessellated with pale brown and yellow spots, the dorsal sepal arcuate and incurved, the sides reflexed, the lateral sepals deflexed; petals minute, triangular; lip minute, 3-lobed. New Guinea. B.M. 7787. G.C. III. 17:429.

BB. *Petals and lip large, the former as long as the sepals.*

c. *Lip cordate-triangular; petals reflexed.*

*Dèarei*, Reichb. (*B. Godseffianum*, Hort.). Pseudobulbs 1-lvd. up to 1½ in. long; lf. up to 6 in. long, acute; peduncle as long as or exceeding the lf., bearing a solitary large fl.; sepals and petals tawny yellow, the dorsal sepal ovate-lanceolate, red-spotted, the lateral sepals lanceolate, falcate, purple-marked on both sides; petals linear-lanceolate, with the veins deeper, and some purple spots; lip triangular-cordate. Origin uncertain. G.C. II. 20:108 (as *Sarcopodium*).

cc. *Lip cordate-ovate; petals merely spreading.*

*Löbbii*, Lindl. Fig. 692. Pseudobulbs 1-lvd., up to 1½ in. long; lf. about 6 in. long, narrowed into a petiole; peduncle shorter than the lf., bearing a solitary large fl. 3–4 in. across; sepals and petals buff-yellow, the dorsal sepal with lines of purple spots on the back, ovate-lanceolate, the lateral sepals falcate, marked with rose in the center; petals lanceolate; lip yellow, purple-spotted, cordate-ovate, acute. Java. B.M. 4532. G.C. III. 38:184 (var. *colosseum*).

AA. *Fls. less than ½ in. long, in a raceme.*

*Careyanum*, Spreng. Pseudobulbs ovoid or oblong, 1-lvd.; lf. up to 10 in. long and 2 in. broad; scape with many bracts, bearing a dense raceme, 2–4 in. long, of numerous fls. which are orange-yellow or greenish, spotted with reddish brown or purple; sepals oblong-ovate, acute; petals broadly ovate, minutely awned; lip nearly entire. Himalayas.

*B. auricomum*, Lindl. Burma. B.M. 7938.—*B. barbigerrum*, Lindl. Lip long, narrow, with a tuft of long purple hairs at the apex. Trop. Afr. Gt. 46, p. 491. B.R. 1942. B.M. 5288. R.B. 30:253.—*B. Binnendykii*, J. J. Smith. Java. B.M. 8187. G.C. III. 47:84.—*B. birmanse*, Schlecht. Fls. orange-yellow, very small. Burma. O. 1910:107, desc.—*B. Bittnerianum*, Schlecht. Fls. golden yellow; bracts leafy, greenish white, rose-dotted. Siam. O. 1910:108, desc.—*B. calabaricum*, Rolfe. Fls. small, light yellowish green, with a dull reddish purple lip. W. Trop. Afr.—*B. campanulatum*, Rolfe. Sumatra. B.M. 8281.—*B. capituliflorum*, Rolfe. Fls. very small; sepals and petals whitish green; lip deep purple. W. Trop. Afr.—*B.*

*chrysocéphalum*, Schlecht. Dwarf plant: fls. yellow. S. E. Asia.—*B. comosum*, C. and M. Burma. B.M. 7283.—*B. crenulatum*, Rolfe. Madagascar. B.M. 8000.—*B. cylindraceum*, Lindl. Himalayas. G.C. III. 49:3.—*B. Dayanum*, Reichb. Burma. F.S. 21:2236. G.C. III. 45:194.—*B. dichromum*, Rolfe. Annam. B.M. 8160.—*B. Dixonii*, Rolfe. Fls. small, greenish yellow with numerous dark brown spots; petals with bristle-like tails at the apex. Siam.—*B. Ericssonii*, Kränzl. Fls. umbellate, the sepals and petals green, spotted with purple-brown, the lip triangular, broadly cordate at base, acute, marked with red-brown. Malay Archipelago. B.M. 8088. G.C. III. 21:61; 32:383. O.R. 15:233.—*B. exaltatum*, Lindl. Sepals light green, dotted with brown; lip blackish purple, much fringed. Brazil, British Guiana.—*B. fascinator*, Rolfe. Annam. B.M. 8199.—*B. fuscopurpureum*, Wight. Fls. dull reddish brown, about 1 in. across. S. India.—*B. galbanum*, Riddell. Malay Penin. B.M. 8216. G.C. III. 42:42.—*B. Gentilii*, Rolfe. Scape 1–2 ft. long, bearing a densely fld. spike; fls. scarcely ½ in. long; sepals and petals straw-colored and purple. Trop. Afr. G.C. III. 36:266, desc.—*B. glutinosum*, Cogn. Fls. arranged in 2 rows in short spikes; sepals greenish, spotted inside with red; petals minute, white; lip red. Brazil. O. 1910:108, desc.—*B. inunctum*, J. J. Smith. Fls. larger than in *B. Lobbianum*; sepals densely dotted with purple; petals long and drooping. Borneo.—*B. Kerrii*, Rolfe. Lvs. oblong, deciduous; fls. dull yellow, pubescent. Siam.—*B. kintianum*, Wildem. Similar to *B. barbigerrum*, but the hairs on the lip are not club-shaped. Congo Free State.—*B. lemniscatoide*, Rolfe. Java(?). G.C. III. 45:68.—*B. lemniscatum*, Pax. Burma. F.S. 23:2476. Gn. 35, p. 610.—*B. Lépidum*, J. J. Smith.—*Cirrhopetalum*—*B. lilacinum*, Ridley. Fls. in dense racemes or spikes, lilac spotted with purple. Siam.—*B. longispalum*, Rolfe. New Guinea. G.C. III. 42:211.—*B. macranthum*, Lindl. Burma and Malay Archipelago. B.M. 7208.—*B. mandibulare*, Reichb. f. Borneo.—*B. Medusae*, Reichb. f. Malay.—*B. micropetalum*, Rodrig. A small plant with spikes of tiny transparent green fls. with prominent blackish purple stripes. Brazil.—*B. minutum*, Rolfe. Resembles *B. barbigerrum* but has a broader labellum with white feather-like processes Congo Free State.—*B. mirum*, J. J. Smith. Remarkable for its curious fls.; lateral sepals united; petals consisting of a small round disk with motor filaments. Malaya.—*B. morphologorum*, Hort. Fls. curious in having a small triangular plate between the dorsal and lateral sepals. Siam.—*B. nigræscens*, Rolfe. Sepals yellow dotted with blackish purple; petals and lip blackish purple. Siam.—*B. nudiscapum*, Rolfe. Allied to *B. barbigerrum*. Congo.—*B. orthoplossum*, Kränzl. Malaya. G.C. III. 43:406.—*B. Pahudii*, Reichb. f. Malaya. F.S. 22:2268.—*B. papillosum*, Finet. Raceme twice as long as lvs.; rachis and bracts green; lip dark purple. French Congo.—*B. Péchei*, Bull. Burma. B.M. 7286.—*B. polyblepharum*, Schlecht. Fls. solitary, dark purple. New Guinea.—*B. propinquum*, Hort. Fls. green with dense purple reticulation. Siam.—*B. quadrifarium*, Rolfe. Fls. inconspicuous. Madagascar.—*B. radiatum*, Lindl. Fls. yellowish white, with narrow lanceolate petals and sepals; lf. linear. India.—*B. tremulum*, Wight. E. Indies. G.C. III. 49:291. O.R. 9:361.—*B. tridentatum*, Rolfe. Allied to *B. mandibulare*. British New Guinea.—*B. trifarium*, Rolfe. Fls. arranged like the bracts in 3 rows, dull, lurid purple, with numerous minute darker spots on the sepals. Madagascar.—*B. viræscens*, Thouars. Fls. umbellate; sepals and petals 4–5 in. long, pal-

692. *Bulbophyllum Lobbianum*. (×½)

green, the veins and nerves brown; lip rather fleshy, about ¾ in. long, cordate-ovate, pale green, purple at the base. Java. B.M. 8327. G.C. III. 40:260.—*B. Weddellii*, Reichb. f. Brazil. B.M. 7958. G.C. III. 36:382.

GEORGE V. NASH.

**BULLACE.** A name used in England for half-wild, half-domesticated plums very similar in character to the Damsons. In America there exist no plums for which another name can not be preferred. The bullace, or bullaces (for there are several varieties sometimes

spoken of as bullaces) are usually referred to the botanical name of *Prunus insititia* (e.g., Hedrick, *Plums of New York*, p. 40); but they are also classified with the Damsons, thus taking the botanical name of *Prunus domestica* var. *damascena* (See Bot. Gaz. 27:481.)

F. A. WAUGH.

693. *Acacia cornigera*.

on the under side, so that no water can enter. All the species of true bull-horns have a four-lobed involucre on the peduncle of the flower-spike near the base. The bipinnate leaves have nectar-glands on the rachis and petiole, as in many other acacias, and they are still further provided with peculiar processes on the tips of the leaflets, minute wax-like bodies rich in oil and protoplasm, which Thomas Belt, in his "Naturalist in Nicaragua" (1874), discovered to be used as food by the ants inhabiting the spines, and which in his honor were named Beltian bodies. These apical bodies had long been known, and Linnæus called attention to the nectaries on the leaf-rachis, but Belt was the first to suggest that in return for quarters and subsistence the little ants serve their host as a body-guard of soldiers, and Darwin in his work on the "Effects of Cross- and Self-Fertilization in the Vegetable Kingdom," called attention to Belt's interesting observations and deductions.

Francisco Hernandez, the *protomedico* of Philip II of Spain, sent in 1570 to study the resources of Mexico, figured the peculiar spines and the leaves of one species growing in the Huasteca region of Mexico, in the Tierracaliente, not far from the Gulf coast. This author speaks of the intense pain caused by the stings of the ants and describes their larvæ engendered in the hollow spines. Jacquin, in describing a bull-horn acacia growing near Cartagena (Colombia) in 1763, tells how the little insects rush from the thorns when the tree is struck however lightly, falling upon the unwary intruder and inflicting upon him myriads of burning stings. Long before this (1696) Plukenet had figured the bodies on the apices of the leaflets, and Linnæus himself expressed his wonder as to the function of the extra-floral nectar glands.

In all bull-horn acacias, there are two kinds of leaves with accompanying spines: vegetative leaves in which the stipular spines usually become greatly inflated; and bract-like smaller leaves subtending the flower-

heads or flower-spikes on the axillary raceme-like flowering branchlets, with stipular spines usually small and subulate. The extra-floral glands on the leaf-rachis and petiole are either crater-like and more or less elongated, or round and bead-like, often several in a series at the base of the petiole and sometimes one between each pair of pinne.

The flower-spikes or flower-heads are solitary, geminate, or fascicled in clusters of several in the axils of the small bipinnate leaves on the axillary, raceme-like flowering branchlets. In one species, *Acacia Cookii*, there is apparently no specialized flowering branchlet, but the globose heads are borne in dense clusters in the axils of the large slender-pronged equitant spines. In all true bull-horns the four-toothed involucre is at or near the base of the peduncle. In *A. cochliacantha* the involucre is at the apex of the peduncle, very much as in *A. Farnesiana*. In *A. cornigera*, *A. spadicigera*, and *A. Collinsii*, the spikes are dense, cylindrical and more or less like the spadix of an aroid. In *A. sphærocephala* they are spheroid-ovate or ovate-oblong, with the flowers closely crowded on a fusiform receptacle. In *A. Cookii*, the heads are perfectly globose with the receptacle also globose. In *A. Hindsii*, which Bentham put in a section (*Americana laxifloræ*) apart from *A. spadicigera* and its allies (*Pycnanthæ americana*), the flower-spikes are lax and slender with flowers not very closely crowded.

Between the small flowers are stipitate bracteoles or umbracula which may readily be likened to minute umbrellas with slender handles protecting the flowers before anthesis from moisture and fungus spores. The laminae of these may be ovate-acuminate or hastate and long-pointed, as in *A. cornigera* and *A. spadicigera*; ovate with the margin ciliate, as in *A. sphærocephala*; circular or nearly so, as in *A. Collinsii* and *A. Hindsii*, or very broadly ovate, as in *A. Cookii*.

The flowers themselves consist of a tubular calyx, four- or five-toothed or almost entire, a corolla of four or five lobes, in *A. cornigera* and its allies only slightly longer than the calyx but in *A. Hindsii* about twice as long. They are polygamous; that is, some of the flowers are entirely staminate, others are both staminate and pistillate. The stamens are numerous, with a single pistil in the hermaphrodite flowers rising from the center of the mass; ovary several-ovuled; style filiform, stigma minute, terminal.

In one division, to which *A. cornigera* and its allies belong, the pods are indehiscent, inflated, thin, chartaceous, terminating in a sharp beak (Fig. 693). In another division, to which *A. Hindsii* and *A. Collinsii* belong, the pods are dehiscent (Fig. 696). In *A. Cookii* they are very long and slender and two-valved. In all cases the hard smooth compressed seeds are surrounded by sweetish yellow or orange-colored pulp, somewhat like that found in the pods of the algarroba, or St. John's bread, which causes the fallen pods to be eagerly sought by pigs and other animals. This peculiarity at once distinguishes the bull-horn acacias from *A. arabica*, the type of the genus, which has dehiscent pods devoid of pulp.

Following are the leading species of bull-horn acacias:

695 *Acacia sphærocephala*.

694. *Acacia cornigera*.

A. *Involucels at the base of the peduncle (Basibracteatae, Benth.); pedicelled bracteoles of the fl.-heads peltate. TRUE BULL-HORNS.*

B. *Pods indehiscent thin and fragile, terminating in a sharp, spine-like beak.*

C. *Laminae of pedicelled bracteoles (umbracula) ovate-acuminate or hastate; fl.-spikes dense, cylindrical; inflated spines broadly spreading or incurved, closely resembling the horns of an ox.*

D. *Peduncles of fl.-heads puberulent; laminae of the bracteoles long-acuminate, more or less scabrous above; inflated spines usually brown or chestnut-colored at length.*

A. *cornigera*, Linn. (Arbor cornigera, Hernández). HUITZ-MAMAXALLI. BULL-HORN. CUERNITOS. ARBOL DE LAS HORMIGAS. ANT-TREE. Figs. 693, 694. A shrub or small tree with 1-3 erect sts. and a few lateral branches bearing numerous large inflated spines remarkable for their close resemblance to the horns of an ox or buffalo. The pods are eaten by pigs and other animals. E. Trop. Mex.

DD. *Peduncles of fl.-heads glabrous; laminae of bracteoles short-acuminate not scabrous above; inflated spines usually ivory-white or yellowish.*

A. *nicoyensis*, Schenck. NICOYA BULL-HORN. ESPINO BLANCO. WHITE-SPINED BULL-HORN. A shrub or small tree resembling the former. Occurs in Costa Rica, Guatemala and the adjacent regions of Mex. and Salvador.

CC. *Laminae of pedicelled bracteoles ovate, ciliate, not acuminate; fl.-spikes spheroid-ovate or ovate-oblong; inflated spines not broadly spreading, often V-shaped or U-shaped.*

A. *sphaerocéphala*, Cham. & Schl. BULL-HORN. CUERNITOS DE VERACRUZ. CORNIZUELO. ARBOL DE LAS HORMIGAS. ARBOL HORMIGUERO. Fig. 695. A shrub or small tree resembling A. *cornigera*, from the state of Vera Cruz.

BB. *Pods dehiscent, coriaceous or woody.*

C. *Fls. in globose heads on long thick peduncles clustered in the axils of long fork-like spines; pods very long.*

A. *Coekii*, Safford. BULL-HORN ACACIA OF ALTA VERAPAZ. A small tree or shrub with slender fork-like inflated thorns inhabited by stinging ants. Guatemala.

CC. *Fls. in elongated spikes, borne on special flowering branchlets, in clusters of several, subtended by small bipinnate lvs. with subulate stipular spines or by a pair of spines only: laminae of pedicelled bracteoles circular or nearly so.*

D. *Spikes dense rigid oblong-cylindrical; pods thick and woody, straight or slightly curved, obtuse or shortly acuminate; larger spines swollen at base, usually U-shaped and equitant.*

A. *Cöllinsii*, Safford. A shrub or small tree with inflated U-shaped, olive-greenish or brownish stipular spines curving upward, and sometimes twisted around the branch. S. Mex.

DD. *Spike lax, flexible, linear; pods coriaceous, slender, falcate usually long-acuminate; larger spines very broad and flat, terminating in widely diverging, very sharp points, like an inverted bicorn chapeau.*

A. *Hindsii*, Benth. BROAD-THORN ACACIA. BULL-THORN OF MAZANILLO. BUFFALO HORN. Fig. 696. A small glabrous tree remarkable for its broad flat stipular thorns, which resemble in form an inverted military chapeau. W. coast of Mex.

AA. *Involucel at the apex or above the middle of the slender peduncle; laminae of the bracteoles ovate-ciliate (not peltate); larger spines stout and straight widely diverging. Fls. in globose heads, solitary or geminate, on flowering branchlets, subtended by a small bipinnate lf. with subulate stipular spines or by a pair of small spines only; larger inflated spines at length split longitudinally.*

A. *cochliacantha*, H. & B. (Mimosa campechiana, Miller). SPLIT-THORN ACACIA. SPOON-THORN ACACIA. This species is not a true bull-horn since its peduncles have not a basal involucl and its stipular spines instead of being hollow and subject to the perforations of ants become split longitudinally.

W. E. SAFFORD.

**BUMELIA** (ancient Greek name for an ash-tree). *Sapotaceae*. BUCKTHORN; also IRONWOOD. Woody plants sometimes cultivated in botanical collections, but without particular ornamental qualities.

Small trees or shrubs with milky or gummy sap and very hard wood; branches usually spiny; lvs. alternate, entire, short-petioled; fls. mostly perfect in axillary clusters, long-pedicelled; calyx 5-lobed, persistent;

corolla campanulate, 5-lobed; lobes longer than tube with a small appendage on each side; stamens 5, adnate to the corolla, and 5 petal-like staminodes; ovary 5-celled, pubescent; fr. a 1-seeded drupe.—About 20 species from the southern states to Brazil.

These are evergreen or deciduous small trees or shrubs, usually spiny, with generally obovate to oblong leaves and inconspicuous white flowers on axillary clusters followed by black subglobose to oblong-ovoid drupes. None of the species is of much horticultural value, but as most of them grow naturally on dry, rocky or sandy soil, they may be used sometimes with advantage for planting in similar situations. The hardiest are *B. lanuginosa* and *B. lycioides*, which have proved hardy in sheltered positions at the Arnold Arboretum. Propagation is by seeds.

*lanuginosa*, Pers. CHITTIM WOOD. Tree, sometimes 50 ft.: lvs. oblong-obovate or cuneate-obovate, rounded and often apiculate at the apex, dark green and lustrous above, tomentose beneath, sometimes nearly glabrous at length, 1-2½ in. long; clusters many-fl'd.; pedicels slender, hairy; fr. oblong-ovoid or obovoid, ½ in. long. S.S. 5:247. H.T. 376. Southern states north to S. II<sup>1</sup>, west to Texas.—This is the species most often met with in collections.

*B. angustifolia*, Nutt. Shrub or small tree, to 25 ft.: lvs. persistent, obovate to oblanceolate, glabrous, 1-1½ in. long.; fr. oblong. Fla. S.S. 5:249.—*B. lycioides*, Gaertn. Shrub or small tree, to 25 ft.: lvs. deciduous, elliptic to oblong or oblanceolate, acute, glabrous, 1½-4 in. long; fr. ovoid. Va. to Ill., Fla. and Texas. S.S. 5:248.—*B. tenax*, Willd. Shrub or small tree, to 30 ft.: lvs. obovate to oblanceolate, pubescent beneath, 1-3 in. long; fr. oblong. N. C. to Fla. S.S. 5:246.

ALFRED REHDER.

**BUPHANE** (Greek, *cattle-destroyer*, alluding to poisonous properties). *Amaryllidaceae*. Amaryllis-like bulbs, very little known in this country; culture as for *Brunsvigia*.

The buphanes are large plants, with many red fls. in an umbel with 2 involucl bracts: lvs. appearing late, strap-shaped, thick; perianth tubular; segms. equal and narrow, spreading; stamens 6, exserted, attached on the throat; style thread-like, the stigma small.—Two species in Trop. and S. Afr. The fls. appear before the lvs., being as many as 200 together in a single head-like umbel, on a stout peduncle 1 ft. or less high.

*disticha*, Herb. (*B. toxicaria*, Herb. *Hæmānthus toxicarius*, Thunb. *Brunsvigia toxicaria*, Ker-Gawl). Bulb, 6-9 in. diam., tunicate; lvs. several, distichous, 1-2 ft. long; peduncle or scape stout (6-12 in. high) and solid, compressed, glaucous, bearing a dense umbel. B.M. 1217.—Sparingly offered. Lvs. said to be very poisonous to cattle in S. Afr.; bulb furnishes arrow poison for the natives.

*ciliaris*, Herb. (*Amaryllis ciliaris*, Linn. *Brunsvigia ciliaris*, Ker-Gawl. *Crossyne ciliaris*, Salisb. *Hæmānthus ciliaris*, Linn.). Fewer shorter lvs., and shorter peduncle, bearing 50-100 dull purple fls.; may occur in choice collections. B.R. 1153. L. H. B.

**BUPHTHALMUM** (Greek for *ox-eye*). *Compositæ*. A genus of 7 species of European and W. Asian perennial herbs, sometimes grown in the hardy border. Heads large, with long yellow rays and imbricated involucl bracts: lvs. alternate, entire or dentate; pappus short, often connate into a corona; achenes glabrous. Showy plants of easy cult.

*speciosissimum*, Ard. (*Télékia speciosissima*). Two to 5 ft.: lvs. cordate and clasping, the upper ones oval and acuminate; heads solitary on the ends of the sts., flowering in July and later.

*salicifolium*, Linn. (*B. grandiflorum*, Linn.). Lower lvs. oblong-lanceolate, 3-nerved, somewhat pubescent and slightly serrate; fls. solitary and terminal, large.

*speciosum*, Schreb. (*B. cordifolium*, Waldst. & Kit.). Lvs. very large, cordate, coarse-serrate; fls. very large

696. *Acacia Hindsii*.

and showy, on an upward-thickened peduncle: 3-4 ft., blooming in June and later. J.H. III. 53:187. B.M. 3466 (as *Telekia speciosa*).—The best of all, a bold free and showy perennial growing very close and making good mass-effects.

L. H. B.  
N. TAYLOR.†

**BUPLEÛRUM** (Greek, *ox* and *rib*; of no obvious application). *Umbelliferae*. A genus of 75 species of weedy plants of the Old World, of which one (*B. rotundifolium*, Linn.), is naturalized in the eastern states, and another (*B. falcatum*, Linn.), is cult. in Japan for greens. (A.G. 13:9). Lvs. simple, entire, often perfoliate; fls. umbellate mostly without an involucre except in the species below; calyx-teeth mostly none.

**fruticosum**, Linn. Fig. 697. Shrubby, 3-5 ft.: lvs. oblong, leathery, mucronate, sometimes persistent, usually quite sessile; fls. with a reflexed involucre, the umbels also with a set of bracts, also recurved; fr. oblong. S. Eu.—Suitable for dry, almost sterile, places.

*B. crœcum*, Fenzl. A showy perennial with fls. and involucral bracts bright yellow. Asia Minor.

N. TAYLOR.

**BURBIDGEA** (after F. W. Burbidge, who discovered it in Borneo).

*Zingiberaceae*. Allied to *Hedychium*, but with no lateral perianth segms. and the lip reduced to a small blade. The showy orange-scarlet fls. rival cannas in brilliancy. For cult., see *Alpinia* and *Hedychium*.

**nitida**, Hook. f. Tender herbaceous perennial: height 2-3 ft.: rootstock creeping, matted; sts. tufted, slender; lf.-blades glossy, 4-6 in. long, eared at junction with the sheath: panicle terminal, 4-6 in. long, many-ld.; inner perianth-tube 1-1½ in. long; outer segms. 1½-2 in. long, orange-scarlet, the dorsal one shorter and more roundish than the 2 lateral ones. B.M. 6403. G.C. II. 12:401.

*B. schizochella*, Hort. Dwarfer and more compact in habit than *B. nitida*: Lvs. dull green above, brown-red beneath: fls. orange-yellow. Malaya.

**BURCHÉLLIA** (W. Burchell, botanical traveler). *Rubiaceae*. One species from S. Afr., an evergreen shrub, with opposite short-petioled lvs. and dense terminal clusters of sessile scarlet fls.: corolla tubular, bell-shaped; stamens 5, inserted in the tube; fr. a 2-celled, many-seeded berry. *B. capensis*, R. Br., has been in the American trade, being cult. for its rich, dark foliage and brilliant fls. It is very variable, and has received several names. Three to 10 ft. Prop. by cuttings. Grown under glass. B.M. 2339 (as *B. bubalina*). R.H. 1886:420. J.H. III. 34:81. L.B.C. 7:664. B. R. 466.

**BURDOCK**: *Arctium*.

**BURLINGTONIA**: *Rodriguezia*.

**BURNET** (*Poterium Sanguisorba*, Linn.). A hardy rosaceous perennial, the piquant lvs. of which are sometimes used in flavoring soups and salads. The dried roots are occasionally used as a family remedy. Burnet is little known in this country as a condimental herb. It is worthy a place in the hardy border for the ornamental character of its odd-pinnate lvs. and its little heads of fls. with drooping stamens. The lfts. are very dark green, ovate and notched; sts. 1-2 ft. high, bearing oblong or globular monœcious heads. Of easiest cult., either from seeds or by division of the clumps. Native of Eu.

L. H. B.

**BURNING-BUSH**: *Euonymus*.

**BURRIÉLIA**: *Baeria*.

**BURSÀRIA** (*Bursa*, a pouch, alluding to the shape of the pods). *Pittosporaceae*. Two species of shrubs with white fls. in clusters; sepals, petals and stamens each 5, the petals soon withering; fr. a 2-loculed caps., in shape like that of the shepherd's purse.

**spindosa**, Cav. An elegant spiny shrub or small tree, with drooping branches and pretty white fls., produced in summer: lvs. small, oblong-cuneate, alternate and nearly sessile ½-1 in. long; fls. small, lateral or terminal, mostly terminal in broad pyramidal panicles. Austral. Tasmania. B.M. 1767. Andr. Bot. Rep. 314.—Cult. in S. Calif.

**BURSÈRA** (Joachim Burser, a disciple of Caspar Bauhin). *Burseraceae*. Usually tall trees, with simple or pinnately compound lvs.: fls. small, in clusters, 4-5-parted, with twice as many stamens as petals or sepals, and a 3-parted ovary containing 6 ovules; fr. a 3-parted drupe with usually only 1 seed.—About 40 species of trees in Trop. Amer. For *B. serrata*, see *Protium*.
